If Mr Robson finds that in the cases calling for operation one case in every five has stones in the common duct, and if, as all agree, the mortality of the operation for removal of common duct stones is from 4 to 5 or more per cent greater than for ordinary opening and drainage of the gall bladder, ought we not to operate or remove the stones before they have started to migrate?

COMPLICATIONS

What are the complications produced by a stone in the common duct?

1 *Jaundice*—Jaundice is seldom caused by stones confined to the gall bladder An attack of jaundice with colic is very suggestive of the passage of either thick ropy mucus or of a stone into or through the common duct Jaundice is not necessarily produced by common duct stones, a single stone seems to cause jaundice more certainly than a larger number I have seen several stones packed into the duct when there had never been any jaundice at all, and this is not an uncommon occurrence Kerr says that he finds jaundice absent in 33 per cent of the cases where stones are lodged in the common and hepatic ducts As a result of chronic jaundice, we have a decrease in the ordinary coagulability of the blood leading to persistent and fatal hemorrhage from even unimportant operative procedures Chlorid of calcium probably helps to overcome this tendency, as has been suggested by Mr Robson

2 *Cholangitis*—This may be either acute, going on to hepatic abscess, or in a subacute form, frequently with chills fever, sweating, so intermittent in character as to strongly suggest the diagnosis of malaria, as was recently emphasized by Brewer

In this connection it should not be forgotten that syphilitic cholangitis occasionally gives this same train of symptoms, probably due to the inflammation of or to the formation of a small gumma in the common duct Dr J B Murphy recently reported such a case to me in a personal communication, and I have seen one such case myself, both of these cases were temporarily cured by a course of antisyphilitic treatment

3 *Peritonitis*—This from the ulceration through the duct of a large stone, is a not uncommon occurrence Some of these escape through the intestine others form local abscesses if the inflammation does not become general

4 *Inflammations of the Pancreas*—These are undoubtedly associated with impacted or passing choledochous stones The duct of Wirsung occasionally discharges into the duodenum through a separate opening but usually it unites with the common duct to reach the intestine through the ampulla of Vater In this latter case a small stone may obstruct the secretions from both the liver and the pancreas Infected bile may in this way set up an inflammation of the pancreatic ducts or the interference with the flow may allow the entrance of intestinal bacteria

The fact that pancreatic infections are rare as compared with biliary inflammations has always seemed to me to be an argument against direct intestinal infection as opposed to blood or other channels of contamination For, if the bacteria usually came up from the intestine the shorter and more direct duct of Wirsung would be the course which they ought to follow

5 *Cancer*—This is probably a late or an indirect result of the irritation following the prolonged presence of a common duct stone

It has been my misfortune to overlook stones in the common duct on several occasions some of which I have been able to remove at a later date Others have recovered with a persistent biliary fistula, probably due to choledochous stones In some other cases I have removed common duct stones in patients who had been previously operated on by other surgeons

The question naturally arises, how can we best prevent the leaving of stones in the common duct? By placing a sand bag under the small of the back, and by making an ample incision, say five inches in length, and raising and rotating the liver so as to expose the common duct, according to Robson The small, short incision, while giving room enough to deal with the gall bladder, is not sufficient for thorough exploration of the common and hepatic ducts One should make it a rule to thoroughly explore the common duct by passing a finger through the foramen of Winslow in all gallstone cases before the gall bladder is opened and this should be done even in cystic gall bladder cases due to an impacted stone in the cystic duct for even in this class of cases other stones may at times be found in the common duct

If the common duct is dilated, and especially if the gall bladder is small and contracted, there is probably either an impacted ball valve or a floating stone in the common duct and under these conditions it is justifiable to open and explore the duct with spoon probe or the finger, as advised by Mayo, who also says that the finger is the only certain instrument of exploration

I have seen several ducts which contained stones into which I was not able to pass the finger without using undue force, but when it is possible the finger should be passed into the duct, as a small stone especially if it be lodged near the ampulla can at times only be discovered in this manner

After removing a stone from the common duct, how shall we treat the opening? Usually by draining the duct We hear of late a great deal about drainage of the hepatic duct I can not see that the passage of a tube up into the duct can have any advantage over simply stitching the end of a rubber drain into the opening A continuous or purse-string catgut suture which catches the tube on either side will close the opening in the duct and prevent the bile from passing into the peritoneal cavity If the gall bladder or stump of the cystic duct after cholecystectomy, is treated in the same manner, just as thorough drainage will result as if the tube were passed deep into the common or hepatic duct

The common duct tube can be removed as soon as the catgut softens while the gall bladder tube can remain until the bile becomes sterile

I have operated on fifteen gallstone cases during the past seven months in five of which I found stones in the common duct, at the time of the operation and one other vomited up a gallstone after having an attack of colic the day after the drainage fistula closed Fourteen of these cases recovered, and one died The death occurred in a young woman of 27, who had been sick one year had suffered for three months with constant fever chills and chronic jaundice At the time of operation the gall bladder was found thickened inflamed and adherent containing four gallstones while there were eight in the common duct Infected bile flowed very freely from the time of the operation until her death

She died on the fifth day with symptoms of septic meningitis and cholangitis, her liver reaching to the crest of the ilium At the partial postmortem no peritonitis was found

DISCUSSION

ON PAPERS BY DRS RICHARDSON* AND MACLAREN

Dr Joseph D Bryant, New York City—I believe in free drainage of the hepatic ducts, and regard gallstones as agents of trouble that ought not to be lightly considered As an earnest of the latter fact, we have only to note the outcome of the case of an apparently innocuous gallstone affliction just cited by Dr Richardson Probably the handling of the gall bladder with its burden of gallstones precipitated the attack that followed so soon after the manipulation of the organ If this be true, then, indeed, is emphasized the importance in such cases of all bodily movements, especially those of a lifting, straining or jarring nature that might easily disturb the relations of the gall bladder and its contents, arousing to renewed activity the infecting agents that some time since gained a substantial foothold there In other words, it seems to me that in the presence of gallstones in the gall bladder one has but to recall the fact that irritation produced by their manipulation or movement may beget prompt and perhaps continuous trouble So far as my experience goes, drainage seems to be an important proposition We must remember that the bile ducts are of a limited diameter and more or less firmly related to the contiguous liver tissue They possess the characteristics of mucous membrane, and are subject to the same inflammatory processes Undoubtedly infection forms very largely the basis of all inflammatory troubles at this situation Infection gains entrance chiefly by way of the duodenum and the gall bladder The mucous membrane of the ducts in such instance as it seems to me becomes increased in thickness obliterating the lumen of the ducts completely in some cases and in circumscribed portions of the ducts in other instances causing thereby interference with the discharge of the bile into the larger ducts and no doubt, circumscribed collections in the smaller Since the flow of bile from the liver is accomplished under a low degree of pressure it becomes very easy to understand how its free discharge should be encouraged by drainage under these circumstances Early and prompt drainage in connection with operations should be practiced in proper cases If one but stops for a moment to make comparison between infected liver structure and infected portions of other parts of the body making the same application of the principles of drainage in both, it seems to me that the illustration of the need in gall ducts is complete As to the points of drainage We have two distinct points of entrance of infection one by way of the gall bladder and the other through the common duct Therefore, these points—the common portals of entrance—should be the ones through which it seems best that drainage should be established in proper cases That the gall bladder should be utilized for the purpose of drainage seems to me to be a perfectly clear proposition especially since we know that the gall bladder and the cystic duct are common channels of infection and therefore should become at once the direct channels for the discharge of the infecting agents To remove the gall bladder, leaving an infected cystic duct would perpetuate the continuance of infection I regard drainage of the gall bladder in suitable cases in the manner recommended by Dr Richardson as the proper course to be pursued and I regard drainage of the common duct for similar reasons as being a meritorious proposition It is hardly enough to drain the gall bladder only for the relief of infection associated with the common duct

Dr C O Thienhaus, Milwaukee—I shall confine my remarks to one question which nowadays seems to occupy the most prominent place in scientific discussions of gallstone surgery That is the methods of different operative procedures in vogue for stones impacted in the common duct When we consider the anatomy of the common duct and its anatomic relationship with the duodenum, we can differentiate three distinct localities in which stones in the common duct are found and are liable to get impacted, and according to which different methods of operative procedures must be used

---

*The paper of Dr Richardson appeared in The Journal September 3

Stones in the common duct may be found, first, in that portion which lies above the duodenum, the so called supraduodenal portion of the common duct, second, stones may lie in that portion of the common duct which is situated within the wall of the duodenum and near the papilla, the so called papillary portion of the common duct, third, stones may be impacted in that portion of the common duct which lies behind the duodenum, the so called retroduodenal portion of the common duct In the first class, stones in the supraduodenal portion, when there exists no possibility (and such a possibility is extremely rare) to press them back through the cystic duct into the gall bladder, supraduodenal choledochotomy with drainage of the common duct, or, better, the hepatic duct is the method par excellence For the second class, impaction at or near the papilla, the transduodenal route as first described by McBurney, 1891 (lithotomia transduodenalis), is the best method, when attempts to dislodge the stone into the duodenum by manipulation have proven futile This method must be followed by drainage of the gall bladder or the supraduodenal portion of the common duct For the third class, stones impacted in the retroduodenal portion, when they can not be dislodged upward into the supraduodenal portion, retroduodenal choledochotomy or transduodenal choledochotomy come into question and are rival operations Retroduodenal choledochotomy was first advised by Lane, 1894 (Clin Society Trans, p 149) An incision is made 3 or 4 cm long parallel to the duodenum descendens through the peritoneum on the outer side of the duodenum (in the same manner as advised by Kocher in cases of gastroduodenostomy) After blunt dissection the duodenum can easily be detached and turned over to the left side, and there by the retroduodenal region of the common duct together with the pancreas, be freely exposed Then the pancreas is dissected (either by blunt dissection, the thermocautery or the knife), the choledochus opened and the stone extracted

Against this excellent method, used by Czerny, Kehr, Kocher, DeQuervain and others with good results, I have but one objection, and that is, that it can only be employed when there are no dense adhesions to be dealt with, and such cases are comparatively rare When we find, as is usually the case (when stones are impacted in the retroduodenal space for a longer period of time), the duodenum, pancreas and common duct matted together in one mass and surrounded by dense adhesions, retroduodenal choledochotomy is inadvisable and transduodenal choledochotomy followed by choledochoduodenostomia interna has to be preferred It is performed in the following manner Opening of the duodenum, incision through the posterior wall of the duodenum to the impacted stone or near the papilla, extraction of the impacted stone and of other stones higher up in the common duct by milking the choledochus from above downward, the index finger of the left hand being introduced into the foramen of Winslow and the thumb lying above the duct When the common duct is freed from stones it is sutured to the posterior wall of the duodenum, thereby producing a new anastomosis between the common duct and the duodenum Then the duodenum is closed and either the gall bladder drained or the common duct from a supraduodenal incision This latter method I used two years ago in a case which I have cited in the Annals of Surgery, 1902, where the woman was jaundiced for over one year and had lost 100 pounds in weight She is perfectly well to day and has gained over seventy pounds since the operation I am not in favor, in cases of impaction of gallstones in the retroduodenal part or the papillary portion of the common duct, of performing a supraduodenal choledochotomy and introducing scoops and other instruments in the dark to dislodge the stone upward Such attempts have been often followed by severe lacerations of the duodenum and the pancreas and subsequent infection or death from starvation (duodenal fistula) Some have objected against transduodenal choledochotomy that it may be followed by infection from the inside of the duodenum In my opinion, the opening of the duodenum is not more dangerous than the opening of the bowel in any other part of the gastrointestinal tract, and statistics have shown that transduodenal choledochotomy is not more dangerous than supraduodenal choledochotomy

Dr J E Moore, Minneapolis—In my experience in gall bladder surgery, I have been impressed with the importance of saving that organ when possible to carry out the very suggestions made by the writer to-day I learned very much from a very recent experience It emphasized the importance of early operation, of thorough drainage, and that it is wise not to give up the patient as long as he is alive The patient was a little girl, 13 years old, who had been jaundiced since she was eighteen months old She had repeated bellyache all this time and had been under the care of a general practitioner The diagnosis recently made was stone in the common duct and there was a clear history of gallstone colic The child's age interfered with early diagnosis, but an operation was performed and stones were found in the gall bladder and common duct I depended on drainage and made what I supposed was sufficient drainage, but it proved to be not sufficient I introduced a cigarette drain with a good sized roll of gauze surrounded by rubber tissue, and all went well for three days The patient was jaundiced after the operation and on the fourth day I was informed that she had a convulsion The temperature was 103, the pulse 130, and I went to see her immediately I decided it was not a case of peritonitis, but that she was suffering from cholemia I thought I could stop the convulsions although when I got her on the table she was semi comatose I used chloroform, removed the drainage from the abdominal cavity and took a blunt instrument and made pressure on the loin Over this I made an incision and found a pint of bile. I irrigated the abdominal cavity with several gallons of normal salt solution, established drainage from the loin, and she is now convalescing

Dr Ernest Laplace, Philadelphia—Dr Richardson is right in saying that a gallstone should be removed as soon as diagnosed Drainage of the ducts is also essential When a rubber tube is used the surrounding parts should be packed with gauze so as to drain whatever leakage that might take place I insist on an abdominal incision long enough to allow easy access to the entire field of operation I have known gallstones to have been accompanied by local malignant disease to which they possibly were the predisposing cause

Dr William J Mayo, Rochester, Minn—I agree with Dr Richardson most fully that early operation in these cases stands in exactly the same position as does the early operation for appendicitis When the operation for appendicitis was done only when the patient was in a most serious condition the mortality was high and our responsibilities to the public were largely increased It used to be said that if surgeons could not give better results they had better leave the cases to Nature, but to day the practitioner himself must bear a part of that responsibility If he does not send his case to the surgeon soon enough he must bear part of the responsibility for the result, and this will be equally true in connection with gallstones There is one particular point that Dr Richardson has brought out, and that is the necessity for bile drainage in probably about 40 per cent. of the cases I can not quite agree that the operation of cholecystectomy is an obsolete one We find ourselves performing this operation more frequently, but it should be for certain reasons If one has a cystic gall bladder where the stone is obstructing and the gall bladder is free from bile, it can be removed, the cystic duct can be ligated and I have seen no harm follow because Nature has already thrown a ligature in the shape of an obstructing stone Some mild cases of cholecystitis with or without gallstones that have given trouble at various times, but are at the time of operation in a quiescent stage, may be removed, and so far as our experience goes, no harm results—but rather good All of these cases, however, should be drained, for occasionally there will be bile pressure and leakage A light catgut ligature protected by a drain is satisfactory If the cystic duct is obstructed by a stone or stricture, leaving a thick walled functionless gall bladder which may really be followed by cancer, I believe these gall bladders are better out You may say that you can take the stones out of the gall drainage I have never seen sepsis result from so doing As to the common duct stones, I think these calculi should be removed and at a primary operation, as this is the safest time You may say that you can take the stones out of the gall bladder and drain, and later remove those in the common duct, but the second operation is more dangerous than it would have been at the primary It is wiser to remove all the stones at one primary operation As to the McBurney operation of duodenocholedochotomy, it is a good operation in a certain class of well selected cases, but it is better to make this operation in conjunction with the operation on the common duct If you open the duodenum and take away the stone there, it may not be the largest stone present, and others may still remain in the duct, therefore, the common duct should at the same time be opened, explored and drained Remove all the stones if you can and you should nearly always be able to do so In rare cases it may be wiser to do a two time operation, and occasionally a stone will be overlooked with the most experienced

Dr J C Bloodgood, Baltimore—I hope, in the future, that if I am asked to discuss a paper, that the chairman will be good enough to allow me to speak before Dr Mayo, because when one speaks after him on the subject of gallstones there is but little left to say but "ditto" Our experience in gall stone surgery has brought out conclusions very similar to those just expressed by Dr Mayo The two papers under discussion impress us that there is a change in feeling toward the operation of cholecystectomy After this operation was introduced by Finney some years ago, many surgeons throughout the country were influenced to perform cholecystectomy rather than cholecystostomy in the larger proportion of cases irrespective of the condition of the gall bladder Dr Richardson in his paper did not discuss this point, probably because in a very recent article he has given his view in regard to the indications for cholecystectomy In this paper Dr Richardson limits the indications for cholecystectomy The surgery of gallstones may be divided into three groups First those cases in which cholecystostomy and drainage of the gall bladder are sufficient, second, those in which removal of the gall bladder (cholecystectomy) is indicated, in this group, in some instances, the cystic duct may be ligated, in others it should be left open and drained In the third group either a simple or complicated operation on the common bile duct is demanded. As a rule cholecystectomy should not be performed especially in the complicated cases Cholecystostomy is frequently indicated I prefer, after duct operations drainage through the gall bladder rather than through the common duct The experience in Dr Halsted's clinic is most favorable to the immediate suture of the duct I have recently received communications from all cases of gallstone operated on in the Johns Hopkins Hospital surgical clinic and from a good many outside cases These communications have impressed me with the uniformly splendid results after cholecystostomy in appropriate cases Secondary operations have never been necessary except in those cases in which all the stones were not removed either because they were overlooked (all early operations) or because the condition of the patient contraindicated the necessary manipulations The experience in gallstone surgery during recent years most emphatically indicates the earliest possible removal of gallstones and the drainage of the gall bladder in cases of inflammation without the gallstones The chief mortality after these operations is found among those cases in which the stone is in the common duct and in which jaundice has been present many months. In every one of these instances there should have been no difficulty in making the proper diagnosis at a much earlier stage of the disease

Dr. Richardson—The main subject of my paper is the drainage of the biliary passages and the indications for operation In answer to Dr Bloodgood I believe certain gall bladders must be removed whereas others are better drained The best practice is, when possible, the preservation and drainage of the gall bladder In those cases in which we must remove the gall bladder we are learning the immediate and the permanent effects of cholecystectomy When I take out the gall bladder I am having trouble, but just what this trouble is I do not yet know Whether this trouble is caused by inflammatory processes about the remains of the gall bladder and the cystic duct, by gallstones, by adhesions, or by neoplasms, time only will tell Drainage is the chief thing to accomplish—whether we provide it through the gall bladder, the cystic, the hepatic or the common duct I am convinced that cholecystostomy is the preferable operation whenever the gall bladder is normal or comparatively normal Diseased gall bladders, with hypertrophied and contracted walls, and gall bladders that are friable poorly nourished and gangrenous, I should remove

Dr MacLaren—I have had the same experience as Dr Moore, due to leakage of bile about the drain, either from the gall bladder or the common duct The method which will most frequently prevent such a leakage is a purse string suture of catgut tied down tightly on the rubber drainage tube This is easily applied about an opening in the fundus of the bladder and it is almost as easily placed about a common duct opening My experience with a number of these cases is that they drain freely and that there is no difficulty in keeping the patient dry while the tube is in place

---

THE ANATOMY AND RADICAL CURE OF INGUINAL HERNIA *

DANIEL N EISENDRATH, A B, M D
CHICAGO

An accurate conception of the anatomic relations of the inguinal region in its normal condition and again when a hernia is present is essential to the surgeon The inguinal canal as we find it during the course of an operation differs somewhat from that as we know it from our dissections

Normally there is no inguinal canal after the testis has descended into the scrotum Even prior to the migration of the testis from its position just below the kidney to the inguinal canal, the latter contains a pouch or diverticulum of peritoneum which is the vaginal process

If the testis remains in the inguinal canal or even in the upper part of the scrotum (just outside the external abdominal ring) this pouch remains open and a hernia results in the majority (50 per cent) of cases of undescended testis

The same sort of a pouch fills the inguinal canal in the female independent of the descent of any organ of generation

When the testis has descended into the scrotum in the normal manner there is no longer an open inguinal canal but only a vas deferens and its vessels in the male and the round ligament in the female

It is of more than passing anatomic interest to study the constituents of the various walls of the normal so-called inguinal canal because many of the modern operations for the radical cure of hernia are based on the desire to restore these conditions as fully as possible

One of the first points to remember is that the internal or deep abdominal ring (see Figs 3 and 5) is situated about an inch above and somewhat to the outer side of the middle of Poupart's ligament The anterior wall of the canal is thus formed by both muscular (internal oblique) and fascial (external oblique) aponeurosis fibers in its outer third In its inner two-thirds the anterior wall is formed by the external oblique aponeurosis alone (see Fig 4) strengthened by the intercolumnar fibers

These are the conditions as they exist in the male In

---

* Read at the Fifty fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy and approved for publication by the Executive Committee Drs DeForest Willard, Charles A Powers and J F Moore

the female the internal oblique, on account of the greater length of its attachment to Poupart's ligament (see Figs 2, 3 and 5), assists in forming the anterior wall in its outer two-thirds This greater protection and the fact that there is no structure to transmit which varies so in size as the cord, probably accounts in part for the lesser liability of females to inguinal hernia

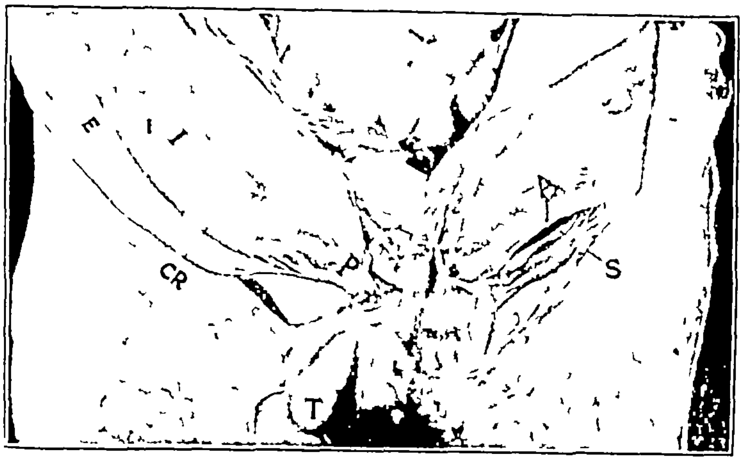

Fig 1 —Dissection of inguinal region Observe undescended testis on right side E External oblique aponeurosis turned back I Internal oblique muscle P Conjoined tendon T Non descended testis CR Cremaster muscle S Spermatic cord A Arching fibers of internal oblique and transversalis

There can be no longer any question that where the cremaster muscle or its fascia are well developed, they play a rôle in protecting the cord on the anterior wall (Fig 1)

The posterior wall of the inguinal canal in both sexes is formed by the transversalis fascia, which is somewhat strengthened by the conjoined tendon of the internal oblique and transversalis muscles just behind the external ring, i e, in its inner third

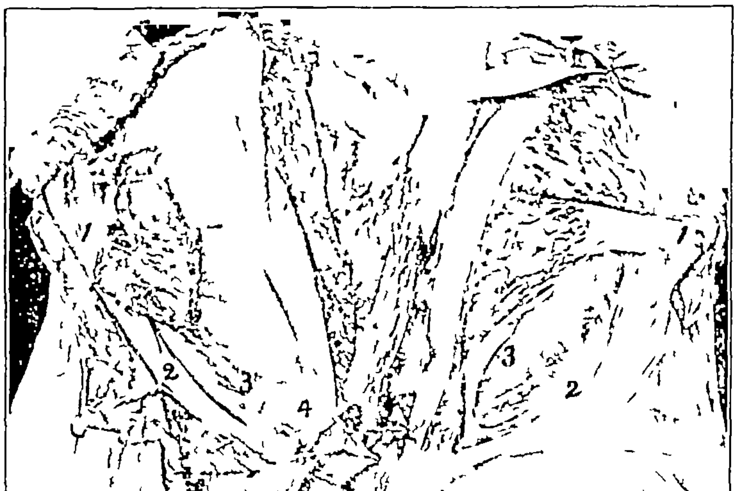

Fig 2 —Dissection of inguinal region of female 1 Anterior superior spines of ilium 2 External portion of aponeurosis of external oblique turned back 3 Internal oblique muscle showing attachment to outer two thirds of Poupart's ligament 4 Conjoined tendon and sheath of rectus

The roof or upper wall is formed by the arching fibers of the internal oblique and transversalis muscles That this arch is shorter in females follows from the greater attachment to Poupart's ligament referred to above (Fig 2)

The floor of the inguinal canal is formed by the shelving edge of Poupart's ligament and when the cremaster is well developed, also by this portion of the original internal oblique muscle

In the child the canal is relatively shorter and straighter than in the adult

In an examination of twenty-five male and nine female normal adult cadavers Dr R C Turck of Chicago[1] found that the average length of attachment of the internal oblique was to the outer two-thirds of Poupart's ligament in the male and to the outer four-fifths of the same structure in the female Drs A H Ferguson and Turck state that a smaller extent of attachment is a factor which greatly favors the origin of an oblique inguinal hernia through taking away one of the anterior supports of the deep or internal ring My own observations have just begun in regard to this point, but in ten male cadavers which I have so far examined the findings were those which are given in the standard text-books of anatomy (Henle Cunningham, Gray, Joessel and Hughes), viz that the internal oblique is normally attached to the outer half only of Poupart's ligament

I mention this fact because one of the arguments advanced in favor of not transplanting the cord and for suturing the internal oblique to Poupart's ligament in front of the cord is that it restores the normal anatomic conditions There are undoubtedly cases of hernia in which a congenital deficiency in the insertion of the internal oblique exists, but their number is a small one

I have taken especial care to observe the internal oblique in a large number of hernia cases and have never observed a case in which the insertion of this muscle was less than to the outer half of Poupart's ligament

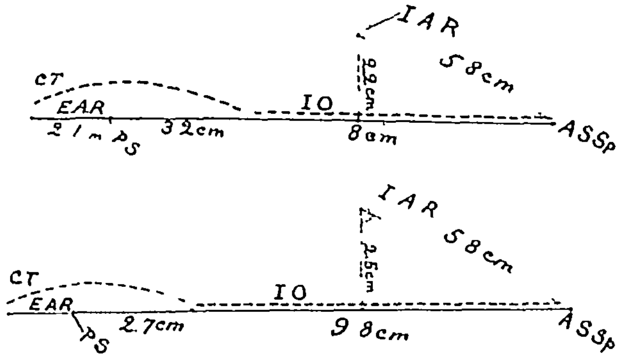

Fig 3 —Taken from article by Dr R C Turck Relation of normal attachment of internal oblique muscle (IO) to Poupart's ligament and to the internal or deep abdominal ring (IAR) CT Conjoined tendon EAR External abdominal ring PS Pubic spine AS SP Anterior superior spine of ilium The upper figure represents conditions in 25 adult males the lower in 9 adult female cadavers

We must look farther for the anatomic factors which favor the origin and development of oblique inguinal hernia, and these are the laxity of the support which the internal ring and posterior wall receive from the transversalis fascia and conjoined tendon

As regards the latter, J B Blake found in twenty-five dissections that the extent of the insertion of this tendon seldom exceeded five-eighths of an inch This has been confirmed by the observations of Bloodgood

A study of the recurrences of radical cure cases shows that in the majority it takes place at or near the internal ring This may be due in part as Halstead and Bloodgood have shown to the space which must be left for the spermatic veins unless they are ligated and dropped back In other cases it is no doubt due to the fact that the muscles which were sutured to Poupart's ligament have retracted or that too much faith was placed in the strength of the conjoined tendon and this part of the canal not sufficiently strengthened

The smaller herniæ, especially if congenital do not cause much enlargement of the internal ring or pushing aside of the arching fibers of the internal oblique or transversalis These structures normally act as a sphincter when the abdominal muscles are contracted, to help strengthen this weak point in the abdominal wall

---

[1] The Journal A M A April 15 1899

The larger herniæ, such as the scrotal, tend to drag on the inner edge of the deep or internal ring so as to cause a considerable enlargement of the same

Every surgeon who has occasion to perform many radical cure operations will frequently encounter cases in which the internal ring has become so greatly enlarged as to lie opposite the external At the same time the gap lying between the arched fibers and Poupart's ligament and the edge of the rectus becomes a considerable one These are the cases in which a plastic operation with the employment of strong structures to fill the defect is needed It is the object of this paper to show that the modification of the original Bassini operation first suggested by Dr E Wyllys Andrews in 1895[2] is the ideal one to use in such patients as well as in those where the defect is not so great.

Before describing this operation permit me to briefly review the chief objects of the various methods of radical cure which are being most frequently employed in this country and abroad

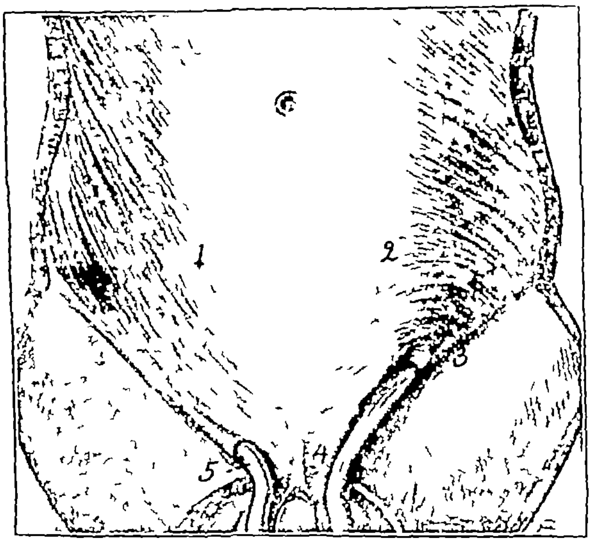

Fig 4—Dissection of inguinal region (superficial layers) 1 Placed on aponeurosis of external oblique muscle 2 Placed on aponeurosis of internal oblique muscle 3 Extent of attachment of internal oblique to Poupart's ligament (outer half) 4 Conjoined tendon of internal oblique and transversalis muscles 5 Spermatic cord emerging from the external abdominal ring

The original Bassini operation (see Fig 10) aimed to strengthen the normally weak posterior wall of the inguinal canal by suturing the internal oblique and transversalis muscles to the inner aspect of Poupart's ligament behind the cord Coley made a valuable modification by inserting a suture above the cord, thus enabling the operator to still further reduce the space left at the upper angle of the wound for the passage of the cord and its vessels The fact that in 917 of his cases there were only 11 recurrences certainly speaks well for this operation These were all cases in which the cord was transplanted In 20 in which it was left behind the muscles there were six recurrences In many of the cases a fatty or atrophied internal oblique or a weak conjoined tendon were no doubt the cause of the recurrence The Bassini operation with the additional suture suggested by Coley is still the operation of choice with the majority of surgeons

Such cases of fatty and atrophic or deficient internal oblique as well as the other causes of recurrence after the typical Bassini operation, led a number of surgeons to devise methods in which the cord should be left in its natural bed, resting on the transversalis fascia and not transplanted The internal oblique and transversalis muscles are thus sutured to the inner side of Poupart's ligament in front of the cord

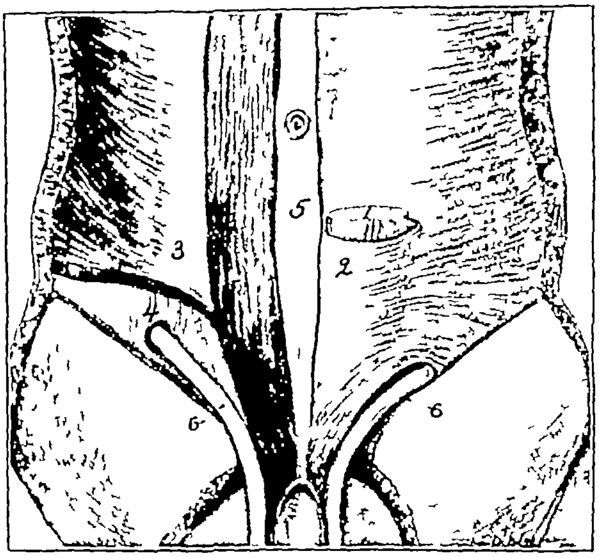

Fig 5—Dissection of inguinal region (deeper layers) 1 Body of rectus muscle lying in its sheath 2 Sheath of rectus formed here by aponeuroses of external oblique internal oblique and transversalis muscles 3 Aponeurosis of transversalis muscle 4 Transversalis fascia and internal or deep abdominal ring 5 Linea alba 6 Spermatic cord

I will describe these briefly in the order of their publication In 1892 Wolfler[3] suggested suturing the internal oblique and transversalis to Poupart's and closing the remainder of the gap by also bringing the edge of the rectus or its sheath to the same ligament.

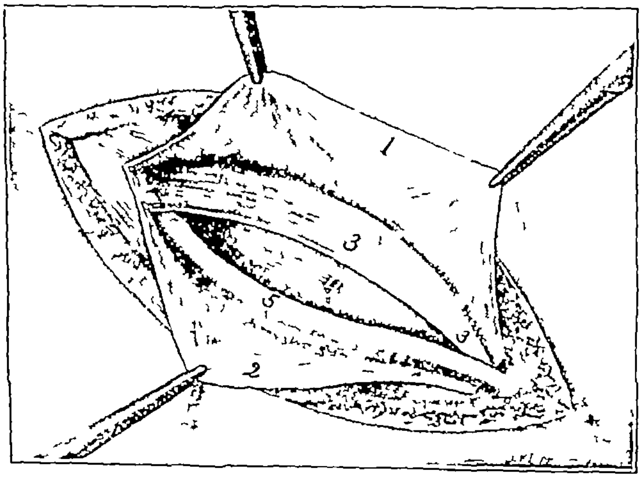

Fig 6—Inguinal canal laid open by incising the aponeurosis of the external oblique muscle (Step 1 of Andrews operation) 1 Internal portion of external oblique aponeurosis 2 External portion of external oblique aponeurosis 3 Edge of internal oblique muscle. 4 Transversalis fascia 5 Spermatic cord.

In 1899 the excellent report by Dr Bloodgood[4] again called attention to his own method of transplantation of the rectus in closing the defect at the lower angle of the wounds

---

[2] Chicago Med Rec August 1895

[3] Wiener medizinische Blätter No 43 1892

[4] Johns Hopkins Hospital Reports vol vii 1899

In the same year Dr A H Ferguson[5] described the operation named after him He laid stress on the observations made by Dr Turck on cadavers (referred to at the beginning of this paper) and to his own clinical experience to the effect that the extent of the normal insertion of the internal oblique was the outer two-thirds of Poupart's In his operation he aims to restore normal anatomic conditions by suturing the internal oblique and transversalis to Poupart's in front of the cord (Fig 10) At the same time he diminishes the size of the internal ring in the transversalis fascia by sutures

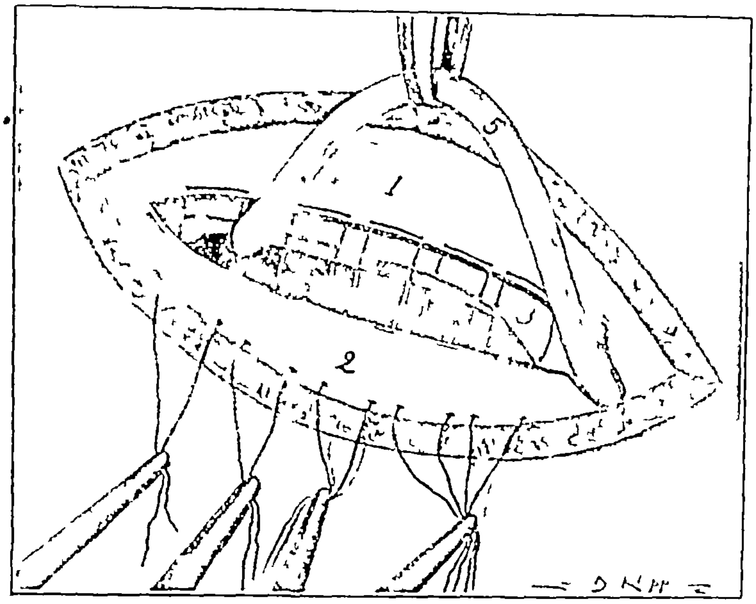

Fig 7—Step 2 of Andrews operation This illustration shows how sutures have been inserted through the internal portion of the external oblique aponeurosis (1) and the edges of the internal oblique (3) and transversalis (4) muscles and carried through the shelving edge of Poupart's ligament and close to the insertion of the external portion of the external oblique aponeurosis (2) One suture is placed above the spermatic cord (5), which is held to one side and 2 to 4 below it (See text)

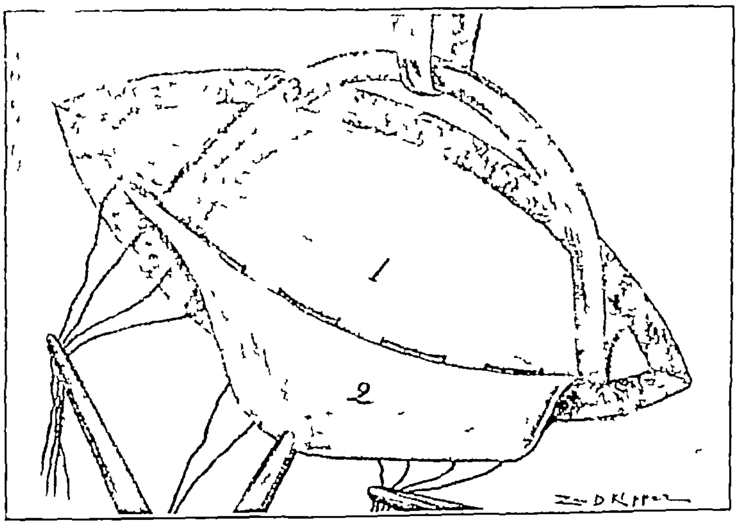

Fig 8—Step 3 of Andrews' operation The structures which have been included in the sutures above and below the cord (3) are drawn over to Poupart's ligament just before tying the sutures and replacing the cord between its new coverings which are the internal (1) and external (2) portions of the external oblique aponeurosis

In 1900 Ch Girard of Berne[6] published a method (see Fig 10), which he states was previously described by one of his students in a thesis in 1894 This latter, so far as I am able to learn, never was published in any journal prior to 1900

Girard advised suturing the internal oblique and transversalis *to Poupart's* ligament without displacing the cord At the same time he imbricates the external oblique edges in a manner similar to that of Andrews (to be described below)

In 1903 Dr W S Halsted[7] (see Fig 10), described the method now in uniform use at the Johns Hopkins Hospital, in which the cord is left in its bed and its veins ligated when large, and the vein stump dropped back The suture with which the hernial sac is ligated is carried far out under the internal oblique muscle and tied after passing through this muscle The cremaster muscle is then sutured to the posterior surface of the internal oblique The edge of the latter muscle, as well as the anterior sheath of the rectus, is now sewed to Poupart's ligament As a last step the external oblique edges are overlapped as in the Andrews operation

In 1895 Dr E W Andrews[2] described a method which he termed the imbrication or lap joint It consisted essentially of adding a third layer to those which Bassini places behind the transplanted cord This third layer is the inner portion of the external oblique aponeurosis which has resulted from the splitting of this structure incidental to opening the canal The cord is then placed on this layer and the outer portion is brought over it somewhat after the manner of a double-breasted coat

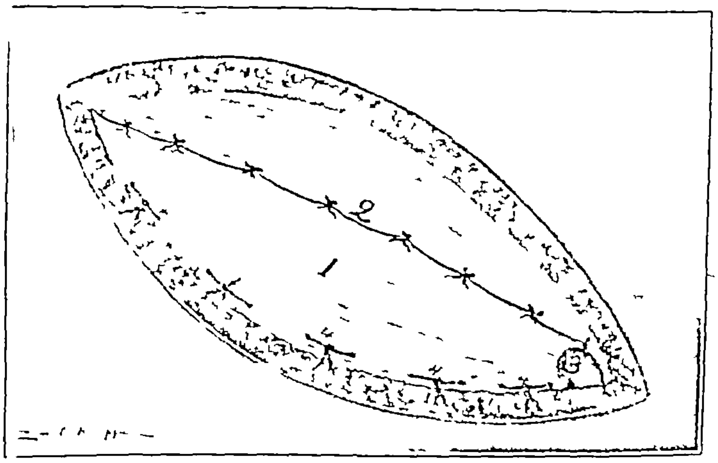

Fig 9—Step 4 of Andrews operation The kangaroo tendon sutures shown in Figures 5 and 6 have been tied The knots (4) lie on the outer side of the external portion (1) of the external oblique aponeurosis The contour of the cord (3) is seen lying in its new canal formed by bringing the edge of the external portion of the external oblique aponeurosis (1) over and suturing it by interrupted catgut sutures to the outer aspect of the internal portion (2) of the same aponeurosis

In this original paper[2] he described and showed illustrations of a number of different ways in which the overlapping could be done In one of these the inner portion of the external oblique aponeurosis, in addition to the internal oblique and transversalis, are sewed to Poupart's in front of the cord

I have mentioned all of these methods briefly to show how different surgeons have striven independently of each other to remedy the defects of the Bassini operation The Wolfler, Ferguson, Girard and recently published Halsted-Bloodgood operation, as well as one of the methods of performing the Andrews operation just referred to, all aim to fill the defect by placing a bulwark of muscles in front of the cord, which latter is not disturbed

[7] Johns Hopkins Hospital Bulletin August 1903

Further experience alone can determine whether we shall adopt these methods universally and discard the transplantation of the cord or continue to transplant by the Bassini or its Andrews modification

Almost any method which completely obliterates the sac alone will suffice for smaller herniæ

For those which are larger and of long duration, in which there is a marked muscular defect and a large internal ring an operation like that of Dr Andrews seems destined to become the ideal one

As early as 1871, Billroth said "the secret of the radical cure of hernia is to find tissues which have the strength of fasciæ This has been accomplished by the operation which I will describe for the purpose of again familiarizing the profession with it The technic is as follows and can be followed by a reference to Figures 6 7 8, 9 and 10

Step 1 —Skin incision having been made from middle of Poupart's to spine of pubes and edges well retracted great care is exercised to secure accurate hemostasis The external oblique aponeurosis is now divided and the two flaps reflected (Fig 6) Sac separated from cord and after being transfixed is ligated with catgut as high up as possible and dropped back The outer portion of the external oblique aponeurosis is made free as far as Poupart's ligament

Step 2 —The cord having been held aside by an assistant kangaroo tendon sutures (Fig 7) are inserted above and below the cord, as follows A needle is threaded on each end of the tendon and the suture first passed through the edge of the inner portion of the external oblique aponeurosis It next includes as much as possible of the muscular fibers of the internal oblique and transversalis and both needles are then carried through the shelving edge of Poupart's ligament The free ends of the suture, after the needles have been taken off lie on the external aspect of the aponeurosis (Fig 7)

The sutures at the angle of the wound which corresponds to the external ring, include the edge of the rectus and conjoined tendon and are inserted as close as possible through the innermost portion of Poupart's where it is reflected on the symphisis pubes One suture above and two to four below the cord usually suffice

Step 3 —The suture above the cord is first tied, then the one immediately below it thus enabling the operator to determine the amount of constriction of the cord The remainder of the deep sutures are now tied the knots lying on the outer side of that portion (outer) of the external oblique aponeurosis, which is attached to Poupart's ligament (see Fig 8) The cord is next laid on the posterior wall of its new canal

Step 4 —The edge of the outer half of the external oblique aponeurosis is brought over so as to cover the cord and sewed by interrupted catgut sutures to the external aspect of the inner half (Fig 8) The skin is sutured with catgut or horsehair

The relations after this operation are well shown by the second diagram of Figure 10 The cord lies in a new inguinal canal whose posterior wall has three layers one of which is a powerful aponeurosis Its anterior wall is composed of one layer of the same strong character

The Andrews operation has been used by a number of Chicago surgeons Drs Andrews, McArthur Greensfelder, Williams Frank Schroeder and myself, in over 1 000 cases, but no attempt has been made to re-examine this large number of cases

In order to determine the results of a number of cases operated on with the same technic by Drs Andrews Greensfelder and myself at the Michael Reese Hospital I sent letters to 110 patients who had been operated on one year prior to June 1, 1903 The majority of surgeons agree with Coley that 80 per cent of all recurrences take place within one year after operation, so that I chose this latter period as a guide

Only those who have attempted the task of examining cases of radical cure of hernia in our larger cities can appreciate its difficulties, so that the comparatively small number of cases examined is no criterion of the value of this operation

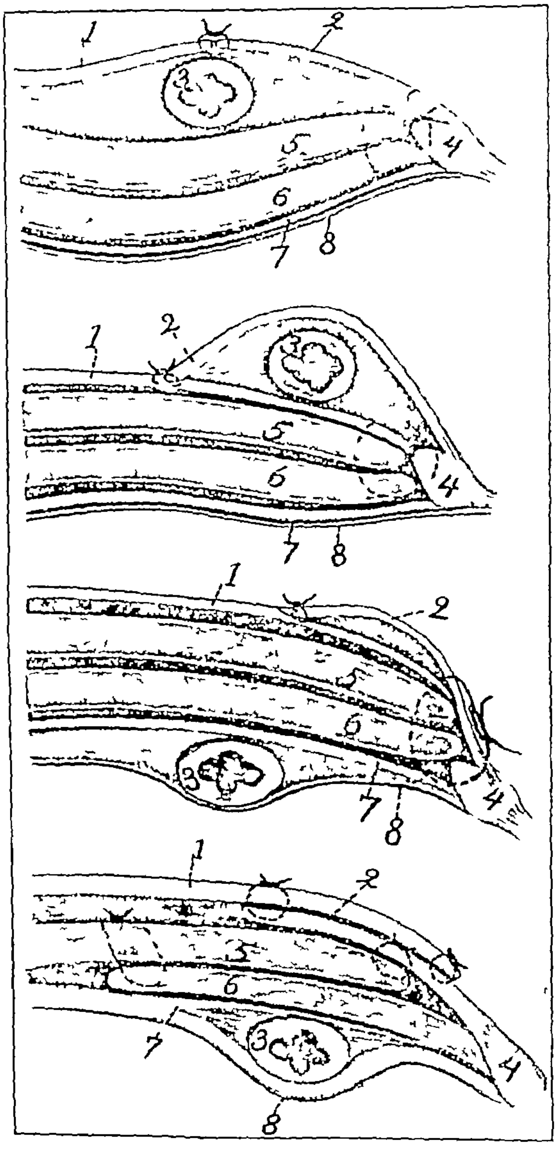

Fig 10 —Arrangement of aponeurosis and muscles in various modern operations (semi diagrammatic) for radical cure of inguinal hernia A. (Uppermost) *Typical Bassini* B (*Second from top*) Andrews modification of Bassini C (Third from top) Ferguson (Girard Wolller) D (Bottom) Halstead Bloodgood. 1 Internal portion of external oblique aponeurosis 2 External portion of external oblique aponeurosis 3 Spermatic cord. 4 Poupart s ligament showing shelving edge 5 Internal oblique muscle 6 Transversalis muscle except in *Halstead* s operation, where represents cremaster muscle 7 Transversalis fascia 8 Peritoneum

Of 110 patients whom we wished to examine 27 were no longer in the city directory Letters were sent to the addresses given in the directory of 52 patients, but none responded Of 28 who were examined by myself there were two recurrences In one of the cases the patient had been operated on five years before, had gained fifty pounds in weight and had become dropsical The hernial protrusion had only occurred two months before the examination, so that the onset of the ascites from cirrhosis of the liver, combined with hard work as a baker, would in a great measure favor a recurrence

The second case of relapse occurred two years after operation in a patient with a severe chronic bronchitis Two other patients answered by letter that their hernia had not recurred and that they were able to do heavy work

As I stated above, it does not seem fair to figure percentages from the 30 cases examined because the other patients are to a great extent of a migrating class, but who would probably come to the same hospital if a relapse had occurred

There is no question in the mind of everyone of us who has employed this modification of the Bassini operation that it is the ideal operation, especially for cases of hernia with large ring and extensive muscular defect

The advantages of overlapping the aponeurotic and muscular structures are that the former while elastic, possess great strength and are not so likely to pull away from Poupart's ligament The sutures placed just above and below the cord enable one to greatly decrease the size of a large internal ring so that it is not necessary to resect the veins unless they are markedly enlarged

At the Johns Hopkins Hospital the early period cases of resection of the veins showed atrophy of the testis in 10 per cent, but in his recent article Halsted states that there have been no unfavorable results since resection of the veins is used as a more or less routine measure when the veins are large Nevertheless the profession in general has been rather skeptical in regard both to the necessity and advisability of such a procedure I have employed the method in two recent cases without bad results

In a hernia associated with non-descent of the testis the resection of the veins as pointed out by Griffith and Bevan is of great aid in bringing the testis down The fear in general of gangrene or atrophy of the testis is probably an exaggerated one, because the cord receives an arterial supply independent of the spermatic vessels

CONCLUSIONS

My conclusions are as follows

1 In the normal inguinal canal the anterior wall is relatively stronger than the posterior

2 This condition is exaggerated in inguinal hernia so that the larger the hernia the greater the muscular gap between the arching fibers of the internal oblique and Poupart's ligament

3 In the smaller herniæ almost any of the modern operations either with or without transplantation of the cord will suffice

4 When the muscular gap is marked some method must be employed in which a strong aponeurotic structure is used to fill the gap

5 The Andrews modification of the Bassini operation, by utilizing a portion of the external oblique aponeurosis as an additional layer in the posterior wall of the canal, gives the latter great strength

6 The majority of surgeons believe best results are obtained by not transplanting the cord It is still an open question whether or not the veins should be resected

NOTE—The discussion on the papers of Drs Eisendrath and McArthur will follow the paper of Dr McArthur in a week or two

THE RELATION OF ACUTE INFECTIONS TO ARTERIOSCLEROSIS *

WILLIAM SYDNEY THAYER, M.D
Associate Professor of Medicine in Johns Hopkins University,
AND
CLINTON ETHELBERT BRUSH, Jr, M D
Assistant Resident Physician, Johns Hopkins Hospital
BALTIMORE

In a recent study in which one of us has been engaged, on the cardiac and vascular complications and sequels of typhoid fever,[1] several rather suggestive facts have come to light with regard to the possible causal relation of this disease to sclerotic changes in the arteries

One hundred and eighty-nine individuals who had passed through typhoid fever under our observation were examined months and years after their infection It was found that among these individuals

(*a*) The radial arteries were palpable in a surprisingly large proportion of cases as compared with control observations on healthy men and women who had never had typhoid fever

Between the ages of 10 and 50, 48 3 per cent of the old typhoids showed palpable radials, as compared with 17 5 per cent among ordinary healthy individuals These proportions held in every decade, and were not essentially modified in tables from which all giving a history of serious infections or alcoholic habits had been excluded

(*b*) The average systolic blood pressure (Riva-Rocci) was materially higher in every decade among the old typhoids than in control observations on healthy individuals who had not had typhoid fever

(*c*) The average size of the heart was larger among the old typhoids when considered in groups arranged by age, according to decade, than in figures obtained from examination of the typhoid patients at the time of admission to the hospital

Furthermore, we have been rather impressed by the frequency with which early endarteritic plaques are found in the aorta and coronary arteries of patients dying of typhoid fever

Out of 95 necropsies on patients dying of typhoid notes were made on the condition of the aorta in 52 In 30 of these sclerotic changes were observed These are described as fresh in at least 21 instances

In 62 cases the condition of the coronary arteries was noted In 19 of these definite sclerotic changes were described, while in 4 others "yellow opacities of the intima" were observed In 13 cases the changes were described as "early" and "fresh"

These figures would tend to support the view that typhoid fever must be regarded as a factor in the production of arteriosclerosis The rôle of infectious diseases in the production of acute arteritis in medium-sized and smaller vessels is undoubted Their influence, however on the development of the more chronic changes which are included under the term arterio sclerosis has been and still is a disputed question

[1] Thayer On the Late Effects of Typhoid Fever on the Heart and Vessels, Am Jour Med Sci, 1904 vol cxxvii, p 391 Thayer On the Cardiac and Vascular Complications and Sequels of Typhoid Fever, the Jerome Cochran Lecture Mobile Medical and Surgical Journal, 1904, vol v No 1

EDITOR'S NOTE—One of the authors wishes it understood that the spelling used in this article is according to the standard adopted by THE JOURNAL

It occurred to us that some light on the relative influence of acute infections as compared with other, probably more important causal factors might be obtained by a consideration of the records of palpability of the peripheral arteries in a large number of consecutive histories of patients in Professor Osler's wards In these histories careful inquiry is made, not only into the record of previous infectious diseases, but also into the habits of the patient with regard to alcohol and heavy work

It may be well to say at the outset that these figures deal entirely with the records of palpability of the radial arteries It is well recognized that the palpability of a radial artery alone may bear little relation to the existence of sclerotic changes in other vessels and, in the individual case, by no means justifies the assumption that arteriosclerosis exists elsewhere It is also recognized that, in thin subjects, radial arteries which are free from change may at times be rolled under the finger On the other hand, it is common enough to find grave changes in the aorta, coronary arteries and other vessels with perfectly soft radials Again, in the later decades, the palpability of the radials is, in a certain proportion of cases, dependent on calcification of the media, which is entirely independent of arteriosclerosis as such Notwithstanding these considerations, we believe that changes in the radial arteries sufficient to justify a note in the course of an ordinary visit are in a considerable proportion of cases associated with arteriosclerotic changes elsewhere, and that this proportion is large enough to give a certain value to a series of observations such as we wish to present

CHART 1 —Showing the percentage of cases in which the radial arteries were papable in patients giving the histories of various acute infections, alcohol and work compared with those cases in which there was a history no causal factors

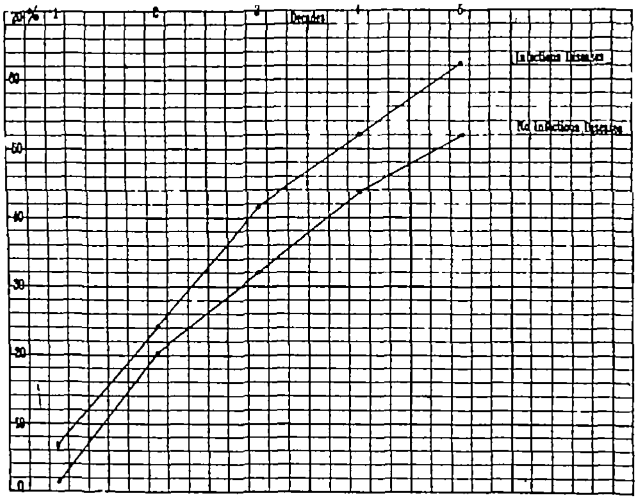
Pr ct	0	43.6	59.4	64.8	70.8	Alcohol
Cases	1	103	589	490	357	
Pr ct	0	48.1	58.1	68 [illegible]	69.6	Work
Cases	0	83	340	312	254	

Out of 3,894 consecutive patients admitted to the medical wards of the Johns Hopkins Hospital, the radial arteries were described as palpable in 1,860 instances, or 47.7 per cent No note was made as to the condition of the vessel in 1,192 cases, while it is expressly stated that the arteries were soft in 582 cases

These cases were separated into groups in which a history was obtained of diphtheria, scarlet fever, malarial fever, typhoid fever, pneumonia, rheumatism, syphilis, gonorrhea, alcohol and heavy work Another group consisted of those cases presenting none of these causal factors It should be said that under alcohol are included, not alone those who used alcohol to excess but all patients who acknowledged that they took alcohol in any form

Chart I shows the proportion of cases showing palpable radial arteries in each one of these groups arranged according to age by decades Recognizing the fact that, above the age of 50, the proportion of cases showing calcification of the media might well be large enough to materially vitiate the results, we have considered the figures for the first five decades only

CHART 2 — Showing the percentage of cases in which the radial artery was palpable in 2,031 cases in which a history of the more serious infectious diseases was obtained and 1,111 cases in which there was no such history arranged according to age by decades



Pr ct	6.8	24.3	41.8	52.1	62.1	History of infectious diseases
Cases	44	255	664	619	149	
Pr ct	0.8	20.2	37.0	43.9	52.3	History of infectious diseases
Cases	119	25[illegible]	350	241	149	

It becomes evident from a glance at this chart that the statistics with regard to syphilis and gonorrhea must be of little value on account of the absurdly small proportion of cases in which a history of venereal disease was acknowledged The curves fall into three main groups Those for work, alcohol and syphilis stand materially above the others Below this group comes a second, consisting of the remaining acute infections and lastly, toward the base line is the curve of those cases in which the history of no causal factor was present Rheumatism, typhoid and malarial fevers seem to lead in the second group

In order to gain a more definite idea of the statistics with regard to infectious diseases in general, the cases were divided into two groups according to the presence or absence of a history of the above-mentioned acute infections In each of these groups the percentage of cases in which the radial arteries were palpable was estimated This resulted in a demonstration (Chart 2) of the fact that the radials were palpable in considerably higher proportion in those cases giving a history of previous infectious disease

Inasmuch as in the great majority of cases each individual presented a history of multiple causal factors, it seemed to us important to prepare a third chart in which there were included only those cases where a single one of these factors was present When considered from this standpoint, the number of cases in each group is so small that a consideration of curves by decades becomes impossible

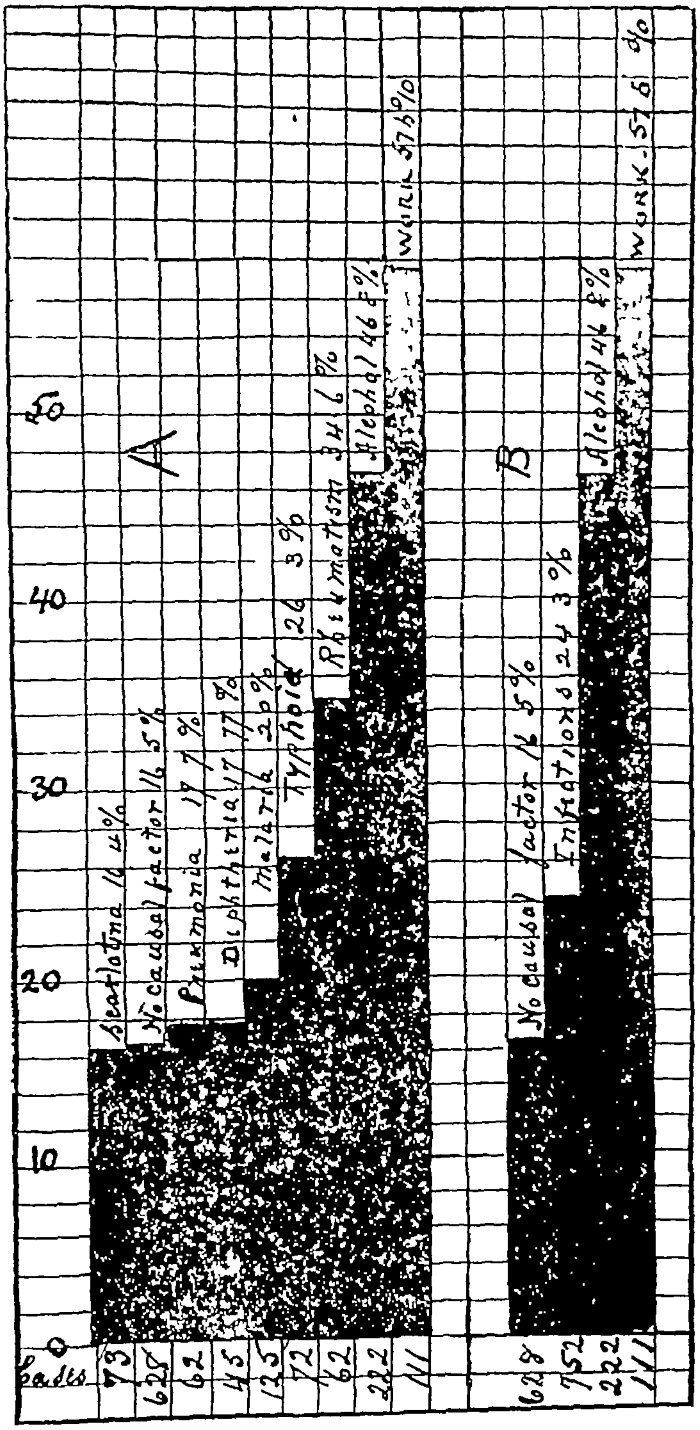


Chart 3

Figure A in Chart 3, therefore, represents the proportion of palpable radials in the first five decades of those cases in which a history of only one of the several causal factors which we have mentioned was present

An examination of this chart reveals the fact that the figures simply emphasize those brought out by Chart 1 By far the highest percentage of palpable radials was found among the cases with a history of heavy labor (57 6) Next to this come the figures for the patients who gave only a history of alcohol (46 8 per cent) Among the acute infections, rheumatism, as might be expected, leads (34 6 per cent), with typhoid fever second (26 3 per cent), the other infections occupying a subordinate position

The cases giving a history of syphilis and of gonorrhea alone were so absurdly small in number that they have been omitted from the list Only 12 cases under 50 years of age gave a history of syphilis alone, among these were 2, 16 6 per cent, who showed palpable radials, 10 cases gave a history of gonorrhea alone, in 40 per cent of these the radial was palpable

Chart 4 illustrates the proportion of palpable radial arteries in those cases in which there was a history of acute infections only, along with those presenting a history of alcohol and work alone The lower line represents the cases in which there was a history of no causal factor

CHART 4—Illustrating the percentage of cases showing palpable radial arteries in patients giving a history of heavy work, alcohol or infectious diseases alone as compared with those cases in which the history of a causal factor was obtainable

	1	2	3	4	5	
Pr ct	0 82	16 6	21 4	18 6	32 6	No causal factors
Cases	121	186	167	102	52	
Pr ct	7 1	15 4	23 9	26	30 8	Infection alone
Cases	42	149	255	188	118	
Pr ct	0	35 4	43 7	56 9	63 0	Alcohol alone
Cases	0	31	80	65	46	
Pr ct	0	68 0	50 0	60 0	58 3	Work alone
Cases	0	25	42	20	24	

The relation of the percentages of palpable radials in these several groups is brought out more clearly in Figure B of Chart 3 The small proportion of palpable radials among the cases giving a history of acute infections alone (24 3 per cent), as compared with those giving a history of heavy work (57 6 per cent) or alcohol (46 8 per cent), stands out strikingly

CONCLUSIONS

As the result of an analysis of the records of nearly 4,000 patients entering consecutively the medical wards of the hospital, we find that

1 The percentage of palpable radial arteries is materially higher among those individuals in whom there is a history of heavy physical labor and of the use of alcoholic stimulants than in the remaining cases This

percentage is appreciably higher in the cases giving a history of heavy work

2 The percentage of palpable radial arteries is higher among those cases presenting a history of severe infectious diseases than among those in which this history is absent or among those in which a history of no causal factor could be obtained The proportion is, however, far below that in the case of work or alcohol

3 Rheumatism appears to be the acute infection after which the percentage of palpable vessels is highest, and next to rheumatism, typhoid fever

As previously stated, it is well recognized that the results of such an investigation as this justify only rather rough generalizations

Are we even warranted on a *post hoc propter hoc* principle, in assuming that work, alcohol and, in a subordinate way, the infectious diseases are the main or important causes of the changes which result in palpable radial arteries? Not necessarily It is, however, not uninteresting that the results should, so far as they go, support the generally accepted views

It seems to us there can be small doubt that the main etiologic factor in the development of the hyperplastic thickening of the intima, which constitutes so important an element of arteriosclerosis, is overstrain of the vascular walls, continued or intermittent high tension, whatever its ultimate cause may be Heavy physical labor is assuredly one of the most important of these causes It is not inconceivable that the rôle of the acute infections may be rather in the production of those focal degenerations with secondary regenerative changes which constitute the other important element in arteriosclerosis

ARTERIOSCLEROSIS OF SYPHILITIC ORIGIN *

C TRAVIS DRENNEN, M D

HOT SPRINGS, ARK.

Undoubtedly syphilis is quite capable of producing, and does produce, in certain instances, arteriosclerosis, but the existing relationship is somewhat obscure

There is no disease in the whole category of diseases which brings to view so many and varied symptoms as syphilis, and it would be singular, indeed, if it did not enter as a causative factor in the production of arteriosclerosis when taking into consideration its known tendency to produce sclerosis in various organs

That syphilitic arteritis and endarteritis do occur not infrequently, and that, too, early during the history of this disease, is recognized as a fact both by clinician and pathologist, furthermore, there is probably no disease which is so amenable to treatment, if such be instituted prior to pathologic changes which are not absolutely beyond repair It will perhaps ever remain an open question as to just how syphilis attacks the vessels but enough is known to lead us to presume that it comes about through the lymph spaces supplying the vessels

I have often wondered if one day we would not come to recognize that vascular changes invariably occurred prior to organic changes in many of our so-called nervous diseases Nerve-cells must be fed and any alterations of the vessels themselves necessarily would secondarily bring about a starvation process provided such alteration became permanent

That arteriosclerosis is responsible for locomotor ataxia in certain instances and that syphilis enters largely as a factor in bringing about these results is a view regarding which I have rather firm convictions I have long been persuaded that arteriosclerosis does not depend on any specific irritant for its production, but that in all cases a combination of elements enter as causative factors Any agent or combination of agents that is continuously left to circulate within the vessels which are foreign to normal cell life will sooner or later be followed by the very changes now under consideration, no matter whether said agent or agents be alcohol, lead syphilis, auto-intoxication, or otherwise To me it is passing strange that a drug like mercury, which is more commonly used in the treatment of syphilis than any other, and has been for ages past, has not been considered one of the chief agents in the production of arteriosclerosis When we come to consider the fact, it would be almost marvelous if at times we did not recognize the possibility, and even the very strong probability, of such being true, when we know so well the method commonly adopted by the profession at large to-day in the administration of mercury for the relief of syphilis

What has been the custom and teaching of some of our very best writers regarding this subject for the past quarter of a century? Have we not been led to believe that the so-called tonic treatment of syphilis with mercury was the only royal road to success? Has it not been the practice of many physicians to prescribe mercury for a period of two years, practically without interruption?

I maintain that mercury is a metallic poison and altogether foreign to normal cell production, and when it is thrown into vessels, and there left to circulate for many months, and even years, whether done on the advice of a physician or through self-prescribing we will find an agent that is just as capable of producing arteriosclerosis as syphilis or any other agent

So many times has it happened that patients have come to my office who have been under continuous syphilitic treatment for many years, and, after having given a complete history of the affair, draw from their pockets a little bottle of mercury pills or of some other pharmaceutic preparation, and relate with painstaking care just how much of this very much abused drug they have been taking during the past three or five years—daily, as the case may be—practically without interruption It is common enough, I assure you, to warrant me in the belief that to-day more persons are treating themselves for syphilis than are under treatment by regular physicians With this reckless senseless and indiscriminate use of a drug like mercury, need we expect otherwise than to find arteriosclerosis resulting particularly so when combined with one of man's oldest and most treacherous *enemies*, syphilis?

A Law in Puerperal Pathology?—The *Semana Medica* No 10, 1903 quotes Corminas to the effect that in his large experience he has never known a fatal case of puerperal infection associated with acute mammitis Recovery is the invariable rule when the puerperal infection is accompanied by an acute mammary lesion He suggests that the presence of a lesion with attenuated infection may induce the formation of antibodies which exert a favorable influence on the virulent focus in the uterus It is possible, he adds, that if fixation turpentine abscesses were made in the breasts instead of elsewhere they might have a more powerful immunizing action especially in case of infection involving the genital apparatus

ARTERIOSCLEROSIS OF NEPHRITIC ORIGIN *

GEORGE DOCK, M D

ANN ARBOR, MICH

Perhaps many of you will think of the celebrated chapter on "Snakes in Iceland" in connection with the title assigned to me Most authors on the subject say little or nothing in line with the view suggested, some dismiss it by saying that arteriosclerosis is a common cause but rarely a result of nephritis, while others say that nephritis and arteriosclerosis are often combined and due to the same cause A few admit that nephritis may cause arteriosclerosis by the prevention of elimination and the throwing into the circulation of substances that either injure the walls of the arteries directly or increase vascular tension, so causing hypertrophy of the heart high pressure and later disease of the arteries

It is doubtless true that in many cases the arterial disease causes the renal disease It is of great clinical importance that the kidney lesion may be very severe, yet latent, and we often see how, under the influence of an acute intoxication, as in infectious diseases, severe symptoms may suddenly develop, and quickly cause death when advanced renal degeneration is discovered In pneumonia, influenza, appendicitis and many other diseases such events often far outweigh the importance of the acute malady It is generally accepted that a chronic nephritis, either interstitial or parenchymatous in a person with previously healthy blood vessels, may cause arteriosclerosis by retention of injurious substances, which act either on the walls of the vessels or cause reflex spasm The arterial spasm in turn is assumed to be either general or largely renal It is often supposed, also, that in interstitial nephritis the mechanical obstruction to the circulation assists in causing high pressure, and, as every parenchymatous nephritis is associated sooner or later with some interstitial change, it is easy to explain many cases of arteriosclerosis on the grounds just mentioned But it is well to remember that there is a great deal of assumption and no actual knowledge of such processes

The recognition of the earliest stages of arteriosclerosis is only beginning to assume a practical character By the use of instruments for measuring blood pressure, and by the more careful study of symptoms and physical signs, it will be possible to put this subject on a more definite basis than at present

The relation of acute nephritis to arteriosclerosis is also a promising field for observation Hitherto comparatively little has been done If chronic nephritis can injure vessel walls by poisonous substances or spasm, there is good reason for thinking that acute nephritis can do so In fact, the toxic symptoms in acute nephritis are often more marked than in chronic cases, and if the duration is often short we must believe that sufficient time is not rarely present for serious damage of tissues Moreover, the edema that occurs early in some cases of acute nephritis is generally, and I think correctly, ascribed to an injurious action of products of disease on the blood vessels, and even if these are smaller vessels the ultimate danger must still exist

The pathology of such processes has been assigned to abler hands, so that I need not discuss it I wish to call attention to the value of clinical study The importance of hypertension in causing vascular disease is now well recognized The detection of the supposed toxic substances and the explanation of their mode of action on the cells need not detain us now If there is hypertension in acute nephritis, we must admit that it may lead to disease of the intima, followed by compensatory and later, by degenerative changes

There is but little literature on this, but now that methods of investigation are becoming simpler the evidence is certain to increase In a recent case in my clinic, a previously healthy boy of 15 years had acute nephritis following a sore throat so mild that it was not treated by a physician In about three weeks there was slight anasarca, the urine solidified on boiling, and contained many casts, but no blood There were several attacks of uremia of various degrees, and after two months death suddenly occurred in another attack During the whole course of the disease the blood pressure was high, measuring from 170 to 190 mm on the Cook's Riva-Rocci instrument It was interesting to note that with this pressure, and an accentuated aortic second sound there was no evidence of dilatation of the heart

Many cases of acute nephritis apparently as severe as this one recover, and I think we must believe that when they occur they may act as causes of vascular sclerosis Further investigations will show whether the milder affections of the kidney, so common in acute infections are associated with high blood pressure It must, of course, be remembered that the other causes of arteriosclerosis, emotional, dietetic, infectious and toxic, are also to be searched for in such cases What I wish to do now is to assert the possibility of renal diseases of all kinds assisting in the production of arterial disease, and to plead for a more extensive clinical investigation in order to show the extent and, if possible, the explanation

Note —The rest of the papers in this symposium together with the discussion will appear next week

THE UNITED STATES PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE

PART II THE SERVICE AS IT IS TO DAY

(Continued from page 667)

(C) THE FUNCTIONS OF THE SERVICE

The functions of the Public Health and Marine-Hospital Service may be considered two-fold, viz , those of a Marine-Hospital Service and those of a Public Health Service It must not be supposed, however, that any such division really exists in the service An assistant surgeon has a tour of duty at each of the various kinds of work, and is early in his career equipped by practical experience to perform any of the varied duties required of an officer of the Public Health and Marine-Hospital Service These young officers are sent successively to the large marine hospitals, to the quarantine stations, to the immigration inspection stations, and to the hygienic laboratory, in order to round out their professional training

The two classes of work are inseparably associated The splendid clinical advantages of hospitals where over 58,000 seamen are treated annually, and of immigration inspection stations, through which hundreds of thousands of immigrants pass each year, give the young officer an educational experience which will be invaluable to him in his future quarantine work, while the training in the hygienic laboratory and in the practical disinfection of ships at quarantine stations, increases his efficiency in the work required in a modern marine hospital

The service operates 22 marine hospitals, maintains 121 relief stations, where hospital and dispensary treatment is furnished, and treats annually over 58,000 sick and disabled seamen of the merchant marine Its hospitals and relief stations are located at all the important ports of the United States, including Hawaii and Porto Rico

The class of cases treated in the service hospitals is necessarily varied The wide distribution of the hospitals in every climate, from Alaska to Florida and from Porto Rico to Hawaii, insures a wide range of diseases, and even to the hospitals on the seaboard of the United States proper, unusual and interesting tropical diseases are brought by deep-water sailors from all parts of the world

The surgical work of the service covers a very large field, and if we except gynecology, embraces all branches of surgical work The average number of operations requiring an anesthetic performed during the year at the United States Marine Hospitals exceeds 1,300

Beneficiaries of the service are as follows (*a*) All persons employed on board in the care, preservation, or navigation of any registered, enrolled or licensed vessel of the United States, or in the service on board of those engaged in such care, preservation or navigation (*b*) Officers and crews of the Light-House Establishment (*c*) Officers and crews of the Revenue-Cutter Service (*d*) Seamen employed on vessels of the Mississippi River Commission (*e*) Seamen employed on vessels of the Engineer Corps of the Army (*f*) Keepers and crews of the U S Life-Saving Service (*g*) Officers and seamen of vessels of the Coast and Geodetic Survey who are not enlisted men of the Navy (*h*) Seamen employed on U S Army transports or on vessels belonging to the Quartermaster's Department of the U S Army who are not enlisted men of the Army

The service also conducts the physical examination of surfmen of the Life-Saving Service and the examination of the claims of these men for benefits under the act of Congress of May 4, 1882

By law, service officers are also required to serve on boards of retirement for officers of the Revenue-Cutter Service By regulation, the service conducts the physical examination of candidates for enlistment, and of officers for promotion, in the Revenue-Cutter Service, and on request officers of this service are also detailed for duty aboard vessels of the Revenue-Cutter Service as surgeons Examinations of applicants for masters' or pilots' licenses, in which particular attention is paid to the color-sense of the applicant, are conducted for the Steamboat Inspection Service

Examinations of applicants for appointment in the Coast and Geodetic Survey and the Light-House Establishment are also made by officers of the service

The service maintains at Fort Stanton, New Mexico, a sanitary ranch with an area of 38 square miles for the treatment of tuberculous seamen Consumptives are removed from the various marine hospitals and sent to this sanatorium at Fort Stanton with a view to their improvement or recovery, and also to remove sources of tubercular infection from the general hospitals The reports from Fort Stanton Sanatorium are very encouraging, quite a large percentage having recovered and a number leaving greatly improved, in spite of the fact that all classes of cases the advanced as well as the incipient are sent there

The site selected for the sanatorium at Fort Stanton is almost ideal for the purpose It has an elevation of over 6,000 feet, an annual rainfall of from 14 to 17 inches, and a mean average temperature of 55 6 degrees Fort Stanton, as its name implies, was formerly a United States Army post, but had been abandoned for several years when turned over to the Marine-Hospital Service The sanatorium is equipped with ice and cold-storage plants, steam laundry, and a modern system of plumbing, sewage and waterworks It is the intention of the surgeon general to make the station in time self-supporting By irrigation, large crops of hay, grain and garden truck are grown A herd of Jersey and Holstein cattle furnishes abundance of fresh milk and a part of the butter used on the reservation A herd of range cattle is maintained, is growing rapidly, and in time will supply the station with all the beef used

The work done by the service in beautifying the grounds, repairing and altering the buildings, and installing the latest scientific equipment and apparatus makes Fort Stanton one of the finest sanatoria in the United States

PUBLIC HEALTH WORK OF THE SERVICE.

The public health work of the service embraces the maintenance of the national quarantine system, including its insular and foreign service, the enforcement of the interstate quarantine laws and regulations, the prevention and suppression of epidemic disease, publication of the weekly *Public Health Reports* and other publications of professional or scientific interest, the maintenance of a hygienic laboratory for the investigation of disease and matters relating to the public health, and the medical inspection of immigrants

The national quarantine system of the United States, as controlled by the Public Health and Marine-Hospital Service, may be considered under three heads—domestic, insular, and foreign The domestic quarantine service consists of a chain of quarantine stations extending from Portland, Maine, to Cape Nome, Alaska, and covering every possible entrance through which disease might be introduced A few of the stations are still operated by state or municipal authorities, but their number is constantly growing less, and within the past few years the states of Florida, Georgia, Maine and New Jersey transferred their quarantine stations to the Public Health and Marine-Hospital Service

With regard to the few quarantines still operated by state and local authorities, the Secretary of the Treasury is empowered by law to prescribe the minimum quarantine requirements, and state and local authorities are obliged to observe these minimum requirements, but may impose additional ones if they deem fit The surgeon general is empowered, either personally or by the detail of an officer of the service, to inspect the maritime quarantine of the United States, state and local, as well as national, for the purpose of ascertaining whether the quarantine regulations prescribed by the Secretary of the Treasury are being complied with If the state or municipal quarantine authorities should fail or refuse to enforce the minimum rules and regulations prescribed, the President may detail officers to execute and enforce the said rules, and adopt such measures as may be necessary to prevent the introduction and spread of epidemic diseases

The quarantine stations operated by the service number 60, of which 42 are in the United States proper A few of these are merely inspection stations, but most of them are large establishments with hospitals, detention barracks, disinfecting plants located on piers or floats, boarding steamers, and other requisites of a complete quarantine station

By insular quarantine is meant the quarantine as maintained by the service in Hawaii, Porto Rico and the Philippines With the military occupation of Cuba, following the Spanish-American war, the national quarantine system was extended to Cuba, and the Public Health and Marine-Hospital Service instituted and maintained during that eventful period in the history of Cuba an efficient quarantine at Havana and all the subports on the island This rigid quarantine played no small part in the sanitary regeneration of Havana and other Cuban cities by preventing reinfection from without The stations were turned over to the Cuban authorities in smooth running order when the American military forces evacuated the island, and with the stations the Cubans received many expert quarantine attendants disinfectors and acting assistant surgeons, who had been trained by the Public Health and Marine-Hospital Service officers during the period of American occupation

An act of Congress, approved April 12, 1900, provided "that quarantine stations shall be established in Porto Rico at such places as the Supervising Surgeon General of the Marine-Hospital Service shall direct and the quarantine regulations relating to the importation of disease from other countries shall be under the control of the Government of the United States Under this act a complete system of quarantine is maintained by the service at San Juan, Ponce and the other seaports on the island

The service carried national quarantine to the Hawaiian Islands in accordance with act of Congress approved April 30, 1900 and now maintains a complete quarantine system at Honolulu and the various subports

By executive order dated Jan 1 1900, the service took charge of the quarantine work in the Philippine Islands The work there has been very heavy, protecting the islands from infection through the intimate commercial relations existing between Manila and Hongkong, Calcutta, Bombay and other badly infected ports, as well as inspecting, and when necessary, cleansing ships about to leave Philippine ports for the United States The transactions of the Manila quarantine probably exceed those of any other maritime quarantine station in the world, and so well has this work been done that, although cholera was epidemic in Manila, no case of the disease has reached the United States and by excluding fresh infection from other Asiatic ports it has been possible to suppress the epidemic of cholera in the Philippine Islands

The domestic quarantine work is facilitated by a system of inspection and application of our quarantine regulations in foreign ports This system is based on the quarantine law of 1893 which provides that no vessel shall enter a port of the United States from a foreign port without a bill of health from the United States consul or a medical officer of the United States Government, and further provides a penalty of $5 000, to be imposed on any vessel coming into an American port without such bill of health By the same law the Secretary of the Treasury is directed to frame rules and regulations to be observed by vessels at ports of departure and on the voyage and the President may detail a medical officer of the government to serve in the office of the consul at any foreign port for the purpose of making the necessary inspection of vessels to see that the regulations are complied with, to sign bills of health, and to furnish information

In carrying out these provisions, officers of the Public Health and Marine-Hospital Service have been sent to foreign ports whenever such ports have been considered infected or a menace to the United States At various times of national danger they have been so stationed in nearly every European and Asiatic seaport of importance, as well as in Mexican, Central American, South American and West Indian ports

At present, officers of the service are signing bills of health for American-bound vessels in the American consulates, at Naples, Italy, Yokohama, Nagasaki and Kobe, Japan, Calcutta and Bombay, India, Hongkong and Shanghai, China, Tampico, Progresso and Vera Cruz, Mexico, Havana, Santiago, Matanzas and Cienfuegos, Cuba, Bridgeton, Barbadoes, La Guayra, Venezuela, Belize, Livingston, Ceiba, Bluefields, Bocas del Toro, Puerto Cortez and Port Limon, Central America, Guayaquil, Ecuador, Callao, Peru, and Rio Janeiro, Brazil

The quarantine duties of the Public Health and Marine-Hospital Service are not restricted to maritime quarantine but, under the interstate quarantine law of 1890 and the quarantine law of 1893, the government has the right to prevent the spread of contagious disease from one state to another

Section 3 of the act of Congress approved Feb 15 1893, requires that if, in the opinion of the Secretary of the Treasury, the rules and regulations of the several states and municipalities are not sufficient to prevent the spread of contagious or infectious diseases from one state to another, additional rules and regulations shall be made by him, which shall be enforced by the state or municipal health authorities, if they will undertake to execute and enforce them, but if they fail or refuse, the President shall execute and enforce the same and adopt such measures as in his judgment shall be necessary to prevent the spread of such diseases, and may detail or appoint officers for that purpose

Practically the same provisions exist in the act of March 27, 1890, but it is further provided in Sections 2 and 3 of that act that any officer or agent of the United States at a quarantine station, or other person employed to aid in preventing the spread of disease, who shall willfully violate the laws of the United States or the regulations of the Secretary of the Treasury shall be deemed guilty of a misdemeanor, and be subject to a fine of $300 or imprisonment for not more than one year or both, in the discretion of the court, and that any common carrier, who shall willfully violate such rules and regulations shall be subject to a fine of not more than $500 or imprisonment for not more than two years or both, in the discretion of the court

Under this law, regulations have been prepared by the surgeon general under the direction of the Secretary of the Treasury the enforcement of which is one of the duties of the Public Health and Marine-Hospital Service

Epidemics of yellow fever and other contagious diseases are always intimately associated with the sea-faring community, and necessarily the medical officers engaged in taking care of sick sailors became familiar with these diseases, which many physicians seldom or never have opportunity of observing Their stations at seaports placed them at the gateways through which infection must come and made them pioneers in quarantine ideas and methods They manifested interest and rendered assistance during epidemics to local physterns at an early date, and in the Supervising Surgeon's annual report for 1873 exhaustive reports were made by the surgeons in charge at New York, New Orleans, Pensacola, Memphis, Shreveport, Mobile and other ports where yellow fever had appeared These reports were made in response to an order issued by the Supervising Surgeon and, together with the Public Health Reports, contain the only complete record of yellow fever epidemics in the United States, as well as valuable information concerning modes of introduction, mortality, relation of yellow fever to dengue, and methods of preventing its spread

The service as reorganized controlled wholly or in part epidemics of yellow fever in the United States in 1873, 1876, 1877, 1878, 1882, 1887, 1888, 1893, 1897 1898, 1899 and 1903

During these epidemics the service contended for the abolition of 'shotgun' quarantines and unnecessary restrictions on commerce, and while hampered in the earlier outbreaks by state's rights theorists and lack of authority, the service usually succeeded in preventing the spread of the disease and stagnation of commerce Instead of the absolute non-intercourse with infected towns which was insisted on as soon as yellow fever was discovered, the service substituted the detention camp in which refugees from infected places could be held under observation for the requisite number of days corresponding to the period of incubation of the disease and then released

The service has controlled, or assisted in controlling, epidemics of smallpox in Alabama, Arkansas Florida Georgia, Texas, West Virginia and other states When cholera had gained admission to Jersey City in 1895 service officers took charge of the situation, and there was no spread of the disease The work accomplished by the enforcement of the quarantine regulations of the service in preventing the entrance of cholera into the United States can be illustrated by the following example

After cholera had been declared epidemic in Naples, three vessels left for the United States—the *Massilia, Weser* and *Cashmere*—and all were made to conform to the regulations They all arrived at the port of New York, with no cholera en route or at time of arrival During the same period four vessels, with the same class of passengers and their places of origin similar, in many cases identical, the water and food supply being the same as on the vessels of the United States, left for South America, and all were turned back by the South American authorities and returned to Naples One the *Vincenzia Floria,* had about 50 deaths, the *Andrea Gloria* 90 on the way out, total not ascertained Another, 84 deaths, and the fourth, 230 deaths from cholera

The work done by the service in suppressing bubonic plague in San Francisco and yellow fever in Texas is a matter of recent history Under the direction of service officers the destruction of rats and the cleansing of Chinatown have been so vigorously prosecuted that no case of plague has been reported since February 1904

When the medical officers of the Public Health and Marine-Hospital Service took charge of the yellow fever situation in Texas late in September, 1903 the disease had existed for weeks Cases were reported rapidly from widely separated points showing that the disease was disseminated over a comparatively large area, and had obtained a firm foothold in Texas There was an abundance of *Stegomyia* thousands of unscreened water-tanks and other ideal breeding places for mosquitoes There was an entire lack of police or other authority to enforce sanitary measures, and an epidemic of mammoth proportions was raging in the Mexican town of Nuevo Laredo, immediately opposite, as well as in other towns of northern Mexico

In the Texas town of Laredo, the Federal officers, after October 1 screened all cases of fever, oiled water-tanks, and other possible breeding places, and disinfected infected premises and surrounding abodes to kill mosquitoes As a result of these operations, although the population was almost entirely non-immune, less than 10 per cent contracted the disease, while 50 per cent of the population of the Mexican town of Nuevo Laredo were stricken with yellow fever

The vigor of the crusade was not relaxed with the disappearance of the epidemic in the late fall, but the same prophylactic measures were maintained throughout the winter and spring up to the present Daily inspection of all the houses in Laredo was made during the period of greatest danger, and cases of fever of whatever origin were promptly screened As a result, there has been no recrudescence of the epidemic, and it is reported that for the first time in many years the people of Laredo are enabled to sleep with comfort without having recourse to mosquito bars

(*To be continued*)

MEDICAL AFFAIRS IN THE HAWAIIAN ISLANDS

NICHOLAS SENN, M D

CHICAGO

PAGO PAGO, SAMOA, July 21

The recent annexation of the Hawaiian Islands as a territory of the United States has awakened among us a new interest in their agricultural, commercial, professional and educational status The wisdom of the consummation of such an act can not be questioned, as the United States has thereby gained a firm foothold in the Pacific Ocean at a point of great strategic importance and the islands have secured for themselves a permanent form of government and the most advantageous commercial relations with the outside world The inhabitants will be made to feel that

> "In no other state except that in which the power of the people is supreme has liberty any abode, than which nothing assuredly can be more delightful "—Cicero

The islands have natural resources that must be made available to the natives The rapid transitions from barbarism to a kingdom and from a kingdom to a republic, and from a republic to a territory of the great republic have left the agricultural and commercial interests of the islands in an unsettled state which, however, under the new administration will soon be remedied Since the foreigners have taken the reins of government in their hands prosperity and depression have followed each other at variable intervals of time, and the gains have found their way largely into the pockets of a favored few It is to be hoped that under the new rule booms and depressions will give way to a steady and more healthful development of the undeveloped resources in which the natives will reap their legitimate share

The scenic beauty of the Hawaiian archipelago is exquisite The islands are of volcanic origin, mountainous, and clad with verdure and intersected by fertile valleys

HISTORICAL SKETCH OF THE ISLANDS

It is supposed that these gems of the Pacific Ocean became populated by the Polynesians from the distant Samoa Islands about the year 500 A D It is claimed that they were first seen by Juan Gaetano, a Spanish mariner, in 1555, but as he left no record, either at home or on the islands, of his visit their discovery must be credited to Captain Cook, who sighted them in January, 1778, and named them Sandwich Islands, in honor of Lord Sandwich On landing, the discoverer found them densely populated, the people peaceable, hospitable and extremely modest and courteous as they prostrated themselves on his approach and remained in this humble position until he and his escort had passed, a courtesy they always extended to their chiefs He found no indications of cannibalism, but human sacrifices, as in all the South Sea islands, were frequently offered. On his return from a voyage to the west coast of America the next year he was killed by the natives soon after landing at the island of Hawaii, at a place now indicated by a monument to the memory of the intrepid explorer The killing of Captain Cook was provoked by a drunken brawl of his sailors, which incensed the natives, and their wrath centered on the leader of the expedition His body was interred, and not eaten, as is so often claimed The political condition of the islands under the rule of different chiefs was a stormy one, wars between the different islands and tribes being frequent, until the Napoleon of the islands, Kamehameha I—born 1737, died on the island of Hawaii, 1819—after many bitter wars gained supremacy over all of the islands and ruled them in the capacity of a king His reign was humane and wise He abolished human sacrifice and introduced many other reforms most creditable to savage rule With the death of Kamehameha V the reigning family became extinct, and Kalakaua was elected king He died at the Palace Hotel, San Francisco January 20, 1891 His sister, Liliuokalani, succeeded to the throne By a bloodless revolution she was deposed, and the kingdom became a republic, January 19, 1893 After a number of futile previous attempts annexation was effected by an act of Congress, July 14, 1900 The present administration has already made many radical changes in the government of the islands which can not fail in bringing about a more prosperous future

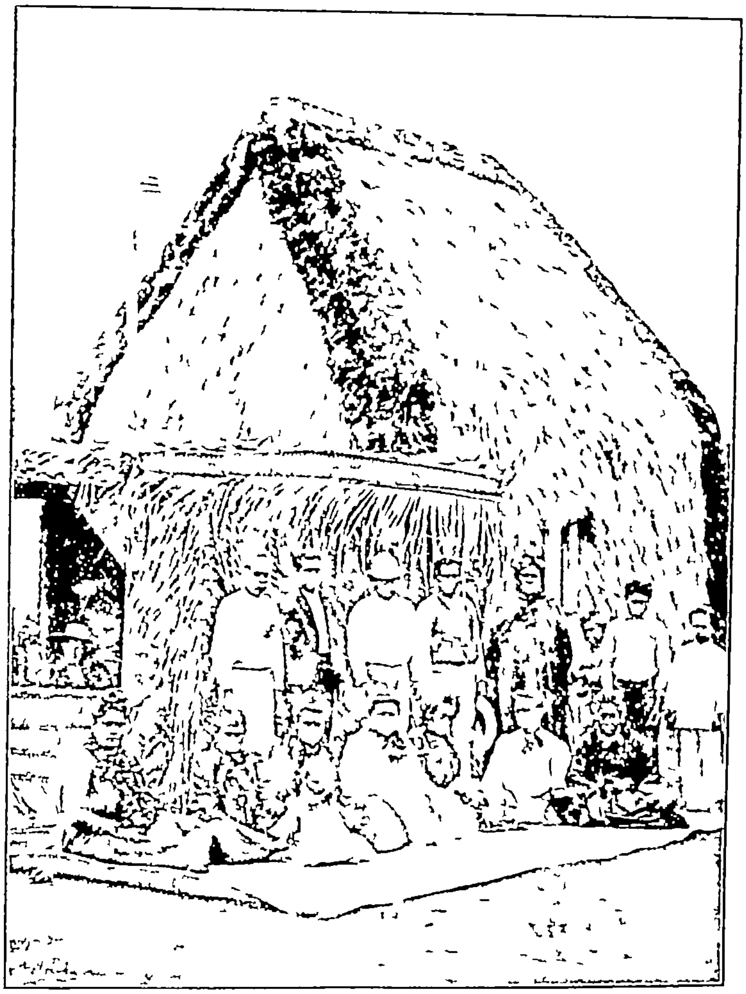

Fig 1 —Natives and native house

CLIMATE

The Hawaiian Islands enjoy an equable and salubrious climate It is the land of sunshine and breezes The northeast trade winds fan the islands 225 to 301 days out of the year, and their cooling and invigorating effects are enhanced by the daily land breezes Anyone who visits Honolulu for the first time and walks or rides along its well paved and clean streets any time of the year from 8 a m to 5 p m may feel the effects of heat and be thrown into a perspiration, when suddenly a land breeze descends from the mountains, cool and refreshing, making the visitor forget that he is in a sub-tropical region It is only when the atmosphere sleeps during midday that the stranger feels at all uncomfortable and seeks relief in the shade The average temperature throughout the year is from 69 to 78 F extremes, 50 to 90 F

NATIVE POPULATION

The Hawaiians are Polynesians resembling in habits and appearance the South Sea Islanders who by migration eastward from the Malay peninsula progressed from island to island, undergoing certain changes under climatic and other influences, but retaining to a great extent their originality In intelligence they are far superior to the negro race, to which they have absolutely no resemblance (Fig 1) Their greatest fault is the inborn indolence The average native makes no unnecessary effort, mental or physical They are as indifferent as children They abhor agricultural pursuits and prefer to live on the waterfronts, where they can secure their fish supply without much effort and amuse themselves with their national sports, swimming and canoe or surf riding They do not take kindly to the professions, and will only work under the pressure of necessity Civilization has rather increased than diminished their repugnance to labor

Fig 2 —Luau feast

The natives are generous to a fault, honest, easy going, with a happy disposition, but have an inordinate fondness for flattery They are very fond of flowers and music, but have little, if any, sense of art The leis (flower wreath) is found on all festival occasions, and is especially conspicuous at the luau feasts (Fig 2)

The mortality among the natives since the whites came to the islands has been frightful When Captain Cook discovered the islands all of them were densely populated, not less than 200,000 In 1836 their number was reduced to 108 579, and at present it does not exceed 30 000 In 1848 one fourth of the population was carried off by an epidemic of measles, shortly after another 3,000 died of smallpox The rapid decrease in the native population and their unwillingness to work creates a field for foreign laborers In 1898 there were in the islands 30,000 Japanese, 24,000 Chinese and 16,000 Portuguese, and since that time the number of foreign laborers must have certainly rather increased than otherwise, as there has been a considerable influx from Porto Rico since the Spanish American war

The effects of civilization on the natives has been harmful as well as beneficial The first missionaries came to Honolulu in 1820, when it was a village of huts, with 3,000 inhabitants For a long time they labored in vain, but in 1837 a strong religious movement swept over the islands and in a very few years paganism had entirely disappeared, at least on the surface Religion, however, did not change the habits of the people to any extent, for

> "Nothing is stronger than custom"—Ovid

The missionaries have brought these people the inestimable blessings of religion and education, but

> 'No sooner is a temple built to God, but the
> Devil builds a chapel near by"—*Herbert*

Education in Hawaii is now compulsory and within the reach of every child. There is no need for any young man or woman to leave the islands for a good general education as Honolulu has most excellent schools including a college and high school

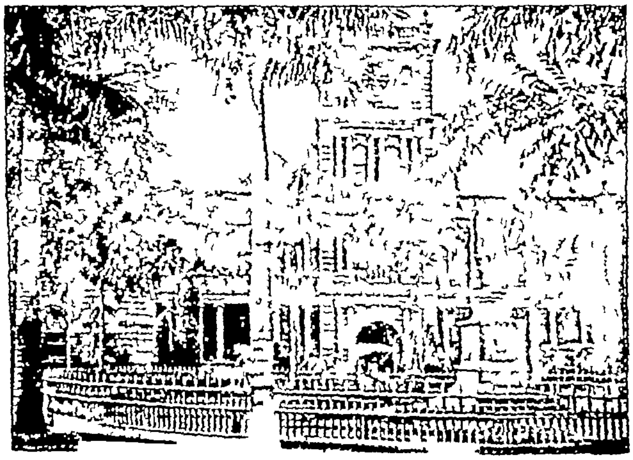

Fig 3—The government house Honolulu

Churches are numerous, both Catholic and Protestant The churches are better attended than in the states, and the people pay closer attention to the worship than our own They are emotional and easily influenced for right and wrong On the whole, the moral status of the Hawaiian would compare well with that of any of our communities On the other hand, the whites brought to the islands the devastating infectious diseases which have already destroyed nine tenths of the population, and which threaten complete extinction The rum shops and gambling are likewise the fruit of the white man s invasion Syphilis was unknown until the sailor and the adventurer disgraced the soil of Hawaii It must not be forgotten that the mind of the aborigines is more susceptible to the reception of vice than virtue, and the Hawaiians are no exception to this rule, so that many of their original natural virtues are on the wane On the whole the natives have paid dearly for what they received from the white man, as the very soil which belonged to them has largely passed out of their hands and is now owned by foreigners

PREVAILING DISEASES

Since the government of the islands has fallen into the hands of the white population every possible effort has been made to protect the natives against the spread of infectious diseases The board of health has been watchful and active in their efforts to improve the sanitary condition of the islands more especially that of the capital city, Honolulu Like all primitive peoples the Hawaiians have absolutely no appreciation of the importance of hygiene and sanitation, and consequently the surveillance of sanitary matters requires constant watchfulness on the part of the board of health

The efficiency of the Hawaiian Board of Health will compare well with any of our state boards It is made up of energetic men, who do their duty fearlessly and without regard to consequences The present board, recently appointed and organized, is made up of Dr C B Cooper, president, Dr W H Mays, S K Kane, Esq, M P Robinson, Esq, F C Smith Esq, E C Winston, Esq, and Lorrin Andrews, Esq

The last report, for the six months ending June 30, 1903 contains much valuable material concerning the present prevailing diseases It is a source of gratification to know from this publication that the reports of the government physicians from nearly every district are unanimous in stating that pulmonary tuberculosis, that has gained such a firm hold on the natives, is not increasing This report shows that during that time occurred 13 deaths from bubonic plague, from typhoid fever, 11, diarrhea and dysentery, 32, pulmonary tuberculosis 84, beri beri, 6, pneumonia, 30 The great mortality from tuberculosis shows to what extent the disease is still prevailing Honolulu, being one of the stations on the ocean highway to the Orient, is constantly menaced with the plague, and notwithstanding the great vigilance of the quarantine physician isolated cases will occur from time to time The stringent measures resorted to by the board of health the moment a case is discovered have so far protected the islands against an epidemic of this much dreaded disease. The most severe outbreak of the plague occurred in 1899 The disease was imported from Hongkong, and broke out among the Chinese and Japanese with great virulence, and soon attacked 80, of which number only 14 recovered A group of suspects of 500 to 700 was quarantined and in this way the further spread of the disease was checked After all danger from infection had been passed the barracks were burned During the entire epidemic only 3 whites were

Fig 4—Queen Emma consort of King Kamehameha III

attacked, and one of them died The same can be said of cholera In 1895 cholera, also imported from the Orient, broke out, but thanks to a stringent quarantine of the 80 or 90 cases, 70 per cent being natives, the disease was promptly stamped out, never extending beyond the limits of Honolulu In 1880 a severe epidemic of smallpox broke out and proved very virulent in the natives, as more than 10 per cent of those attacked died

Compulsory vaccination is now enforced by the board of health, will prevent all possibility of a similar occurrence in the future Scarlet fever has never been epidemic, and diphtheria has always been observed, and that very seldom in isolated cases Syphilis is not so common as formerly, but the hereditary effects are widespread and severe, and present and future generations will be made painfully aware of the truth of

'Posterity pays for the sins of their fathers"—
Quintus Curtius Rufus

Measles has always been the great curse of the primitive races, and it has claimed thousands of the Hawaiian population The fearful mortality attending this disease is usually attributed to the recklessness of the patients, as they will not keep their bed, but will persist in bathing to find relief from the fever heat I believe, however, that such imprudence on the part of the whites would not result so disastrously and that the frightful death rate is more attributable to the slight resistance to the disease on the part of the natives There ought to be very little, if any, typhoid fever in Honolulu under the present perfect system of water supply and sewerage The disease occasionally affects small communities where the sanitary conditions are not so completely under the supervision of the government physicians stationed in the 23 different districts Maui is the island that records the largest number of cases of malaria, 121 cases of dengue and malaria in six months, as stated in the last health report, while Kauai and Molokai report none, and only 3 cases are credited to Oahu and 3 cases of typho malaria and one case of typhoid The islands continue to supply the leper settlement with new inhabitants to take the place of the dead According to the report referred to above the number of lepers at the settlement at present is 888 In six months the population of lepers was increased by 62, at this rate the annual addition to the number of lepers would still be 124 The report also refers to a large number of suspects that remain under observation, and from which a large number will be recruited for the settlement as soon as an absolute diagnosis can be made

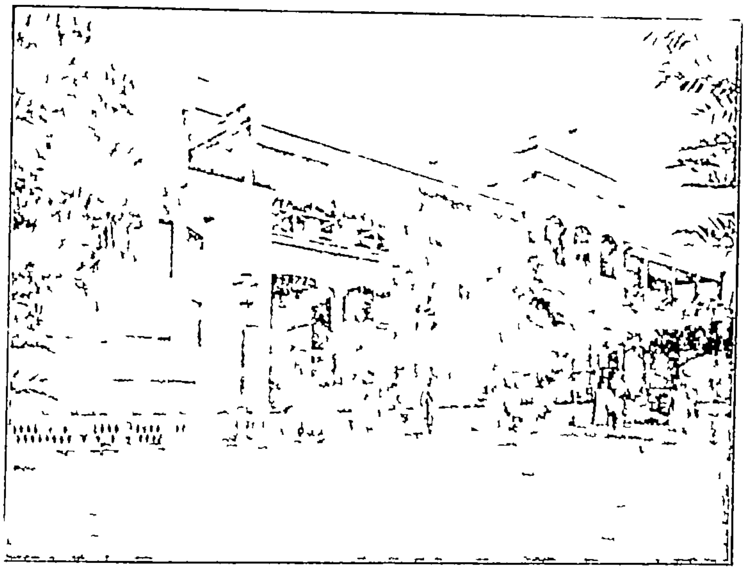

Fig 5—Queen's Hospital, Honolulu established by King Kamehameha III and Queen Emma in 1860

Dr W J Goodhue, a recent graduate of Rush Medical College, has taken up the cause of the Molokai lepers, and is the present resident medical superintendent He has already introduced many reforms, and is earnestly seeking for a remedy that will cure his patients He continues the Goto treatment but has no faith in it At the suggestion of the board of health he is also experimenting with the "Violet Ray" At present he is encouraged by the results of sodium cacodylate In his report he says "In sodium cacodylate, an arsenical derivative of relatively slight toxicity containing over 50 per cent of arsenic, I believe I have found a remedy of great promise in the treatment of leprosy My attention was first attracted to the remedy by clinical reports of the success attained with it in the treatment of psoriasis, and in diseases in which the wasting and disassimilation are marked features, although I can not find any account of its ever having been employed in leprosy It is administered hypodermically, per os, or by rectal enema, and it appears to be entirely free from any appreciable irritative effects on the intestinal or rectal mucosa. I have a limited number of patients on this treatment who, so far, after being on the treatment for from two to three months show very decided improvement, and I am only awaiting a large supply of the drug before materially increasing the number of patients when I hope to submit a detailed and favorable account to the board of health of the results obtained"

Before disposing of the subject of leprosy and in reference to a former communication on the same, I will add that during my short visit at Honolulu *en route* I met a number of the most influential physicians, and they were all unanimously opposed to making the whole Molokai Island a leper home They base their opposition on business principles They, as well as the business men in the islands, fear that if this were done the outside world would be prejudiced against the islands, and in consequence the value of property would be depreciated and business injured There is considerable weight to this argument for the present, but as in the course of time, when it becomes generally known that the colonization of the lepers would be limited to the Molokai Island, such objection would no longer apply Still, this is a matter, as I have stated before, for the territorial and general government to consider and decide

THE MEDICAL PROFESSION

The medical profession of the island territory is one of the most desirable things that we have inherited by the annexation, a worthy addition to the large body of practitioners of the United States It is made up largely of young, energetic men who came here well prepared for their lifework The door of entrance to the practice of medicine is well guarded Every candidate must pass a satisfactory examination before a board of examiners appointed by the governor This board consists of four members who, to judge from the character of the men who have been licensed, make no farce of the examination, as is only too often done in the states The question of school is not considered, all must pass the same critical test, and if found qualified they can practice any system they please There are now about 100 licensed physicians in the islands about 60 in Honolulu, and the rest scattered in the 23 districts

Every district has what is called a government physician, who looks after the poor and sanitary matters, and is paid on an average about $1,000 a month for his services These doctors make a semi annual report of their work to the board of health Through these channels the board of health reaches the most distant parts of the islands, and thus insures prompt and efficient sanitation Among the older practitioners in Honolulu belong Drs McGrew and McKibbin, and Dr W E Taylor, a retired naval surgeon Dr C B Cooper is president of the territorial State Board of Health Dr F R Day, a graduate of Rush Medical College, Dr C B Wood, ex interne at Cook County Hospital, and Dr Walter Hoffmann, a graduate of Germany, are the leading practitioners The sick of the yellow races are cared for by 12 Japanese and 2 Chinese physicians For the benefit of recent graduates I would say that Hawaii has all the physicians it can well support at present it is no Paradise or Eldorado for a new beginner The field is well occupied, as most of the men would be hard to discount, and the present depressed condition of the sugar interests is felt throughout the islands There are only three or four men in Honolulu who have been there for years and who are very popular that can put down their annual income in five figures

Some of the physicians with a smaller income add to it by conducting at the same time some business enterprise

QUEEN S HOSPITAL

Queen's Hospital is the only hospital in Honolulu It was erected and endowed by the late Queen Emma (Fig 4) who took a deep interest in charity work (Fig 5) It is a handsome structure *located in the center of a park* ornamented with flowers and tropical trees and shrubs The palm avenue leading from the street to the entrance of the hospital, is one of the finest *I have ever seen* The hospital is managed by a board of trustees, composed of forty members, and represents the most influential men of the city The hospital has a capacity *for ninety patients* and the new wing which is nearing completion will accommodate an additional fifty Four physicians appointed by the board of trustees constitute the staff Formerly these physicians were salaried, but I presume in consequence of the additional expenditure incident to the building of the new wing, and the depression in the value of the real estate in which *the endowment* largely consists, the salaries have been withdrawn The equipments of the hospital are adequate, and the new operating room will fill *a long* felt want The nursing is in the hands of eight trained nurses, who receive a monthly salary of from $40 to $50 Experiments have been *made to train native young women*, but they failed, so that the hospital is put to the large expense of hiring trained nurses The indigent native sick are amply provided for and others pay according to their means

MEDICAL SOCIETY OF THE HAWAIIAN TERRITORY

The first attempt to organize the medical profession in Hawaii was made through the instigation of Dr H W Howard, in 1893, when the physicians of Honolulu met from time to time in each other's houses, thus combining social with professional *interests Under the above title a permanent organization* has been effected with monthly meetings at which physicians from the different islands attend so far as transportation facilities will permit It is a source of regret that the transactions, so far, have not been published, and, in view of the importance *of the subjects that are discussed from time to time, more* particularly everything pertaining to tropical diseases and island sanitation, the reports of many of these meetings would *make interesting* and profitable reading for the medical world

Clinical Reports.

A PROCEDURE FOR FACILITATING THE EXPERIMENTAL TESTING OF RABIES

A P OHLMACHER, M.D

(From the Pathological Laboratory of the Ohio Hospital for Epileptics)

GALLIPOLIS, OHIO

In the course of a *considerable number* of cases in which our laboratory has been called on *to make a diagnosis* of rabies in dogs or cattle, I have found it possible to expedite the examination and minimize the danger to the operator by a simple method which is not described, and which is original if not novel As is well known to those interested in the experimental study of hydrophobia *the material for examination* which usually finds its way to a laboratory consists either of the carcass or the head and neck of a dog or other suspected animal To prosecute the requisite tests one must obtain certain ganglia for making the rapid histologic examination (the Van Gehuchten Nelis test), and *a portion of the brain or cord, preferably* of the medulla, for experimental inoculation Ordinarily the brain of the suspected animal is exposed by piecemeal clipping off the dome of the skull and the arches of the vertebra by means of bone forceps This process is laborious and dangerous, inasmuch as the operator may injure his hands on projecting spiculæ of bone or be struck by flying osseous fragments The substitute which I have adopted and successfully practiced consists in transecting the skull by sawing after dissecting away the soft parts For this purpose we are *accustomed* to employ the modified butcher s saw recently described and illustrated by my *associate, Dr* W H Buhlig,[1] although any large saw will answer the purpose The line of saw cut is midway between the orbits and the auditory meatuses at right angles to the cranio vertebral axis By means of heavy gloves the hands of the assistant who steadies the head and those of the operator are protected *The sawing is continued until all resistance* by bone beneath the skull is overcome, then the bisected portions may readily be pressed apart and the divided brain becomes fully exposed

With a sterilized spatula the posterior portion of the cerebrum is removed Then the tentorium is chipped away with sterilized heavy scissors, or *bone forceps, though it is possible to dig out the cerebellum and* expose the fourth ventricle without doing this With the dorsal surface of the medulla thus laid bare, it becomes *a simple matter to cut out* with sterile scissors or scalpel, and forceps, one or more small cubes which constitute the material from which the emulsion for experi*mental inoculation is prepared It is our practice to make* such an emulsion for immediate use from one portion of the medulla, *and to preserve another portion* in sterile glycerin for future use Furthermore, we practice two methods of inoculation in rabbits—the intra cerebral injection of Leclainche Morel[2] and the intranasal method of Galtier[3]

It now remains to obtain ganglia for the Van Gehuchten Nelis *histologic test I have found the gasserian ganglia to present* very excellent and characteristic histologic pictures in dogs affected with street rabies, and have accordingly made it a routine procedure to obtain both these ganglia, each of which, because of its large size *may be split on the flat*, one slice being fixed in absolute alcohol or Carnoy's acetic acid chloroform-alcohol mixture for the rapid preparation of sections, after *paraffin imbedding, the other portions being fixed in formalde*hyd solution to prepare for immediate frozen sections or for permanent preservation With the skull bisected as described above, and the brain removed it becomes a *simple matter* to dissect out the gasserian ganglia

Ordinarily it is also desirable to secure one or more intervertebral ganglia to control the histologic test These are to be obtained by *opening the cervical vertebral canal by clipping away* the arches of the vertebra in the usual manner, fully exposing the spinal cord and its nerves with their ganglia

---

METRORRHAGIA IN TYPHOID FEVER

WILLIAM HIMMELSBACH, M D

SAN FRANCISCO

Woman, aged 35 unmarried, presented herself at my office with a temperature of 102 5 F and a history of bronchitis vomiting and general malaise She was at once sent to Lane Hospital In a few days the case was *diagnosed typhoid fever* Enlarged spleen, "*pea soup*" *diarrhea and abdominal spots* manifested themselves, Widal reaction being negative, finally with interval of several days, a positive Widal was obtained thus clinching diagnosis On January 20 there was a pronounced uterine hemorrhage, prior to this the temperature was 103 5, shortly *followed by a drop to 100*, with subsequent rising A careful bimanual pelvic examination excluded any lesion, and close questioning and absence of characteristic odor eliminated the menstrual flow *All efforts* to check the hemorrhage were futile. After two days it ceased spontaneously About the *twentieth day* the temperature declined to 100 2 F , and suddenly, preceded by a pronounced chill, shot up to 104 F An examination *of the chest* demonstrated a pneumonia involving the lower lobe of the right lung

It took the usual course, and the patient was eventually discharged some six weeks later

BACTERIAL INVASION OF THE BLOOD

Examination of the blood of patients for bacteria during life is altogether too infrequently practiced in view of its extremely great diagnostic value, and until the last few years it has been almost entirely neglected In consequence of this our knowledge of the bacteriology of the specific infectious diseases has been largely derived from findings made through cultures obtained at postmortem examinations, and the value of such findings as an index of the conditions that existed during the life of the patient has been open to question It is known that during the last hours of life the resistance of the blood to infection may be so lowered that an "agonal invasion" by pathogenic bacteria may occur Again, putrefactive bacteria are liable to spread from the intestines and make their way through the body, causing postmortem invasion" Hence the actual value of cultures made at autopsy from the heart's blood and the different viscera has been somewhat uncertain Since so much of our information rests on such results as postmortem examination can yield, the publication of results obtained in 1,200 autopsies under carefully supervised conditions is of no little importance Dr M Simmonds publishes the complete report of the bacteriologic examination of the heart's blood of cadavers made by himself and his assistants in the general hospital at Hamburg from 1900 to 1903, and analyzes them critically in a recent number of Virchow's *Archiv*[1]

From their results it would seem that such postmortem examinations, if made within forty hours after death, and on a body kept in a cool, dry place, give a much better index of the antemortem condition of the blood than has generally been believed In such cases as had been examined during life for bacterial invasion of the blood, the findings at autopsy were regularly the same In the rest of the cases the blood was found sterile or infected with whatever organism would be expected to be present in the disease that caused death Postmortem invasion of the heart's blood seems to occur very seldom within forty hours after death if the body is kept cold, and the importance of agonal invasion seems to have been exaggerated

About half of all the bodies examined (48 per cent), death having resulted from all sorts of causes, were found to contain bacteria in the blood of the heart As this blood cools down slowly after death, because of its central location, the number of bacteria is quite different from the number in the circulating blood, for they may multiply greatly after death, but otherwise the findings afford accurate information concerning the blood during the patient's last hours A number of striking facts are developed from these results First may be mentioned the infrequence of mixed infection, for of 575 positive findings in but 26 were two kinds of bacteria demonstrated, and but once three kinds, in 95 per cent a single variety of organism was present in pure culture Of the different forms present, the streptococcus is by far the most important, for it was found 363 times in this series which represents the ordinary causes of death as seen in a large general hospital, while the pneumococcus appeared but 101 times, colon bacillus 97 times and staphylococcus 34 times

In other words, in almost one-third of all fatal diseases as they occur in the population at large, streptococci have entered the blood before death, and presumably played a greater or less part in bringing about the fatal termination The overwhelming importance of this organism is made very apparent by this study It appears in the blood in all sorts of conditions, and in many diseases is probably the chief cause of death Its relation to scarlet fever, which we have discussed in these columns before, is clearly shown, for it was present in 88 of 129 fatal cases, the blood being sterile only in the cases where death occurred in the first three or four days before pharyngitis had set in, or when death was due to nephritis or other complications after the acute stage of the disease was over Simmonds agrees with von Dencker that in most cases the malignancy of scarlet fever is due to this organism but that it has nothing to do with the cause of the disease Streptococci are but little less often invaders in diphtheria and here also enter the blood when there are serious lesions in the pharynx and upper air passages The diphtheria bacilli themselves were not found in the blood once in 68 fatal cases In measles streptococci were found but four times in ten cases

Bacillus coli has generally been looked on as a source of error because of its supposed frequent entrance into the blood and tissues shortly before or shortly after death Simmonds, however, found it in the heart's blood chiefly in diseases in or near to the alimentary canal, and does not consider it likely to be present in the blood after death unless it has entered during the course of the disease Chronic heart disease, nervous diseases poisoning and acute tuberculosis cases gave almost invariably no growths from the blood, showing that our ideas of "terminal infection" "agonal" and "postmortem" invasion have probably been exaggerated

An important observation is that bacteria may enter the blood in large numbers within a very short time after operations and injuries, and later again disappear entirely Also in peritonitis from appendicitis, etc the blood was frequently sterile whereas if the peritonitis followed an operation the blood was almost always infected, apparently indicating that the wound favors the entrance of bacteria into the blood, this must have much effect on the outcome of the peritonitis

---

[1] 1904 vol clxxv No 1

Many fatal cases occur in which, without the bacteriologic examination of the blood, it would be impossible to determine the cause of death, as in acute septicemias, and many others are easily capable of wrong interpretation. It is not going too far to say that any autopsy made without a bacteriologic study of the blood and the organs is but half made No matter how clear the anatomic findings may be, there is always a large possibility that the bacterial findings may alter considerably the final conclusions concerning the case

THE IMPORTANCE OF DROPLET INFECTION IN PULMONARY TUBERCULOSIS

Some three or four years after the discovery of the tubercle bacillus by Koch, the researches of Cornet demonstrated the great part played by dried sputum in the spread of the disease, particularly the pulmonary form In fact, the idea that the inhalation of dried sputum was almost the only, or at any rate by far the most common, method of transmission of pulmonary tuberculosis, gained a strong footing in the medical profession The idea that the tuberculous individual could exhale from the mouth infective material seemed at first an improbability on account of the well-recognized bacteriologic law that bacteria are not detached from moist surfaces Still, it was known to bacteriologists that bacteria could be detached from moist surfaces in the form of a spray, and it remained for Flugge and his pupils to show, in 1897, that in tuberculous individuals during coughing and even during speaking, a fine spray actually is given off the watery droplets of which contain tubercle bacilli As a result of this discovery, Flugge formulated his theory that the inhalation of these droplets, which are found floating in the air for some distance around the patient is one of the important sources of infection in pulmonary tuberculosis There can be no doubt that from a purely experimental point of view the researches of Flugge and his pupils uphold the possibility of this mode of infection Heymann for example, exposed cover-slips in the near neighborhood of thirty-five tuberculous patients while they were coughing, and was able to demonstrate tubercle bacilli in the cover-slips from fourteen of them The same observer was able to produce tuberculosis in guinea-pigs by exposing plates in the neighborhood of tuberculous patients and inoculating the animals with washings from the plates He was also able to produce tuberculosis in six out of twenty-five guinea-pigs by merely leaving them in the near proximity to coughing tuberculous patients

In a recent study Saugman[1] thoroughly reviews the literature of this subject and gives his own conclusions based on an extensive study He points out very properly that theories like that of Flugge, while they are based on sufficient experimental evidence, are often accepted before they are thoroughly tested under natural conditions In the case of droplet infection he points out that we have one class of individuals in whom it should certainly occur if there is anything in the theory namely, physicians in sanatoria for tuberculous patients, and physicians in nose and throat clinics There is evidence to show that in the latter there is plenty of opportunity for infection Tubercle bacilli have been isolated in such clinics from head mirrors, from spectacles worn by physicians, and even from the cheeks of the physician It is apparent, too, that physicians who are daily examining the lungs of tuberculous patients must similarly be exposed to droplet infection As a basis for his study, Saugman collected statistics from a large number of sanatoria and nose and throat clinics as to the history of the physicians who had been employed in those institutions So far as the sanatoria were concerned, it was found that many of the physicians were suffering from tuberculosis when they entered as assistants, but of 174 physicians who entered the sanatoria in perfect health, and lived there three or more years, none had died of tuberculosis, and only two had contracted it The returns from physicians who worked in throat clinics were even more striking, though here a smaller number of returns were obtained Of 64 physicians working in throat clinics who entered on their work in perfect health, not one had contracted tuberculosis

Saugman discusses in a general way the reason for this immunity He naturally finds it difficult to do this on account of our lack of accurate knowledge as to the exact factors which predispose to tuberculosis On the grounds that some local defect in the lungs must be present (local predisposition) he suggests the possibility of its absence in these cases but excludes this, as it would be extremely improbable that such a lack of local predisposition would occur in so many individuals On the same grounds he excludes an immunization due to old healed foci He thinks it possible that physicians of the class mentioned may become gradually immunized against tuberculosis by daily infection with very small doses of the bacilli, and in this connection he points out that the average droplet given off by coughing only contains from one to twenty bacilli, and that the dose needed to infect is probably thousands of bacilli His conclusions appear conservative, he merely states that his study shows that the droplet infection probably plays but little part in the infection of adults in health He fully realizes that the same may not be true of children or those weakened by disease, and he also recognizes the fact that physicians, particularly those living in sanatoria, are under exceptionally favorable hygienic conditions We need hardly point out that among the poor and uncleanly in crowded tenement districts droplet infection may play a much more important rôle. In any event, the results of Sangman's studies, as he himself insists, should not cause us to abate one jot our precautionary measures.

ACID INTOXICATION

It is said that acetone in small quantity appears normally in the urine, but the amount becomes pathologic at times in connection especially with certain disorders of metabolism, of which diabetes is the most familiar example. Of itself it gives rise to no symptoms, but its presence is often associated with that of other substances, especially diacetic acid and beta-oxybutyric acid, and when abnormal phenomena make their appearance they are probably due to the latter. All of these are probably the results of some derangement in fat-metabolism. The development of stupor followed by coma and death, after operations on patients, particularly diabetics presenting acetonuria, has been observed rather frequently, while the occurrence of acid intoxication under various conditions had been earlier recognized.

Drs. E. G. Brackett, J. S. Stone and H. C. Low[1] report a group of cases presenting the following symptom-complex: Vomiting, associated with collapse, weak and rapid pulse, absence of fever until just before death, cyanosis in the fatal cases with extreme dyspnea, apathy and stupor alternating with periods of restlessness at first, but in fatal cases gradually deepening into coma and death, and the presence of acetone on the breath and in the urine. In six cases the symptoms developed in the sequence of operation, while in seven they set in independently of any operative procedure. Of the former three and of the latter one died. The children in whom the symptoms were severe exhibited a high-strung, nervous temperament. The symptoms were in general more severe in those operated on than in those not submitted to operation.

The first symptom to attract attention was the vomiting. The vomitus was always bile-stained, becoming dark but never bloody. Restlessness was at first associated with the vomiting, but occasionally there was a certain amount of apathy either preceding or alternating with periods of restlessness. The milder cases presented a varying degree of restlessness, while in the severer cases collapse was marked. In some of the severe cases cyanosis became pronounced in a short time. Recovery occurred in no case in which cyanosis was marked. As the color changed restlessness was followed in some instances by delirium, but in all of the fatal cases stupor gradually supervened, becoming more profound and gradually passing into coma. In the fatal cases death resulted in from twelve to thirty-six hours after the onset of the symptoms, generally after about thirty hours. Death seemed to be due in some cases to lack of oxygen. Postmortem examination in several cases disclosed fatty degeneration of the liver and of the muscles. Acetone and diacetic acid were found in the urine in practically all of the cases in which they were looked for. In a number of cases muscular atrophy was present.

In the line of treatment the administration of sodium bicarbonate by mouth or in enemata and infusion of large amounts of saline solution proved most serviceable. The etiology and pathology of the condition are obscure, the only satisfactory explanation attributing the symptoms to some derangement of metabolism giving rise to acid intoxication.

MORAL INSANITY

The line of demarcation between sanity and insanity, like that between health and disease, is sometimes so nebulous that it becomes exceedingly difficult to decide where the one ends and the other begins. It is not a matter of wonder, therefore, that differences of opinion should arise in this connection, particularly when the question of responsibility is raised. There has been not a little discussion as to the existence of so-called moral insanity as an entity, but despite the objections to its recognition the disorder has retained its place in mental nosology. Perhaps the term moral imbecility would be preferable. The affection must be looked on as a degenerative one of congenital origin. The general intellectual functions may be unimpaired, while the moral sense is lost in greater or lesser degree.

What must be considered one of the most remarkable instances of moral or criminal responsibility on record has been reported by Dr. H. R. Stedman[1] in the case of an unmarried professional nurse 45 years old, who, there was sufficient ground for believing, had fatally poisoned twenty persons and on several occasions had made attempts at incendiarism. She also twice took poison with suicidal intent, assigning jealousy as the reason for her act. Her favorite method of administering the poisons employed was in Hunyadi water or by enema, combining the drugs in kind and proportion so that the resulting effect was an unusual and perplexing set of symptoms. There were no delusions of enmity or persecution. The patient was examined by a commission of three physicians, appointed by the court as the result of an arrangement between the prosecution and defense, and the conclusion was reached that she was insane and irresponsible at the time of the homicides, without hope of recovery. The patient was accordingly declared not guilty by reason of her insanity, and she was thereon committed to a state hospital for the insane for the remainder of her life. During the trial the attitude of the woman is described as more that of an interested spectator than that of a prisoner on trial for her life.

For a year or more the patient did well, but subsequently developed delusions of persecution and poisoning, with hallucinations of hearing, and her nutrition became greatly impaired. Her father had been an eccentric man, who had placed her and her sister in a foundling asylum. One of her sisters was a chronic dement, mother led a dissolute life As a girl the patient exhibited incorrigible propensities for deceit, falsehood and trouble-making She began her career as a nurse at the age of 28, attending successively two training schools, but being dismissed from both before graduation She was recognized to be queer and peculiar In some instances she secured the removal of patients not agreeable to her by making false charges against them, and in other instances she kept favorite patients in the hospital by reporting the presence of fictitious symptoms

[1] Boston Medical and Surgical Journal, July 21, 1904, p. 57.

ARTERIOSCLEROSIS

The subject of arteriosclerosis is one of perennial interest, and one concerning which, in spite of the immense amount of study which has been devoted to it, much yet remains to be cleared up It has recently been discussed in Germany before the Congress for Internal Medicine,[1] and in this country before the Pathological Society of Philadelphia[2] and the American Medical Association

The paper of Marchand before the German congress which discusses the subject in its wider pathologic aspects, considers under the term arteriosclerosis all those changes in the arteries which lead to a diffuse or nodular thickening of the wall, especially of the intima, in the development of which degenerative, sclerotic and calcareous changes occur This conception necessarily excludes pure hypertrophy of the media, and syphilitic processes occurring in the medium sized and small arteries The essential factor which is at the bottom of all cases of arteriosclerosis according to this author is a mechanical one, *viz*, *an over filling, or temporary or permanent increase of the arterial pressure, which may be due to local injuries, or to general processes in the form of intoxications, general nutritional disturbances, or similar factors* The primary change in the vessel walls in all of these cases is in the elastic coat, and consists of a weakening of this The later changes of a degenerative and sclerotic nature are essentially secondary and compensatory in character Coplin's study, which covers essentially the same ground as Marchand's, leads him to practically the same conclusions, he also lays great stress on the fact that the disease is primarily a disease of the elastica

The importance of increased arterial tension as a *causative factor in arteriosclerosis* is forcibly brought out by the experimental studies of the younger Erb which completely confirm the similar studies published by Josué[3] Erb was able to produce experimentally lesions which essentially resembled those of human arteriosclerosis by frequently injecting into the circulation of animals small doses of adrenalin Coplin has been able in a number of cases of human arteriosclerosis to find lesions in the adrenals and this fact, together with the occasional observation of increased arterial pressure in certain adrenal lesions, such as adenomata, should lead to a much more extended study of these glands in arteriosclerosis Even at the present time certain writers have suggested that arteriosclerosis is always of adrenal origin, and that toxic substances which were supposed to produce vascular lesions directly do so rather by their indirect action on the adrenals which they stimulate and cause to hypertrophy

Inasmuch as adrenalin is being advocated in an increasing number of conditions, and particularly in various forms of hemorrhage, these observations should lead to a care in the selection of cases in which it is used While its temporary use in acute illnesses like typhoid fever seems perfectly justified, it would seem inadvisable to use it for any length of time, particularly as the liability to arterial change which follows this disease is now well recognized It can be imagined that where the hemorrhage is due to, or accompanied by some subacute or chronic vascular lesion, the use of adrenalin might be contraindicated Our knowledge of the action of this substance at present covers almost entirely its action on normal vessels, and only clinical experience will certainly define its dangers In any event caution in the use of this remedy seems indicated

THE ABOLITION OF THE BREAD TAG

It is reported in the daily press that the United Master Bakers, in their recent convention at St Louis, have decided to discontinue the practice of pasting labels on loaves of bread This is an eminently rational decision It is apparently a small matter at first sight, but the unhygienic possibilities of the practice readily suggest themselves It is not a pleasant thought that the union label, pasted on an important article of food, has been stuck there by the spittle of the workman, but it is a probability that can not very well be ignored We all of us have to eat dirt more or less throughout our lives but this does not imply we should be compelled to do so needlessly The bakers' decision is a commendable one and shows that they are properly awake to hygienic demands

THE PRESENCE OF BACTERIA IN THE VISCERA OF HEALTHY ANIMALS

There has been not a little discussion as to whether the solid viscera of healthy animals contain bacteria or not, and the evidence bearing on this question has been most contradictory There are, however, so many opportunities for contamination and loopholes for error in investigations along this line that the reported results can not all be accepted without reservation A valuable contribution to the data on this subject has recently been published by Dr *H deR Morgan*,[1] who made a careful study of the viscera of rabbits, cats and dogs with the strictest precautions, and found micro-organisms *in 26* per cent of the examinations The bacteria however, were those ubiquitous in the atmosphere, and there is reason to believe that their presence was accidental, the germs or their spores probably adhering to the moist surface of the viscera during their exposure in the course of the postmortem examination The correctness of this latter suspicion was demonstrated by exposing sterilized viscera under like conditions, and obtaining the same micro-organisms on culture Accordingly, the conclusion is definitely reached that normal organs do not contain pathogenic bacteria, while the presence of non-pathogenic bacteria in cultures is probably due to accidental contamination

TUBERCULIN IN TREATMENT OF NON TUBERCULOUS AFFECTIONS

A recent communication[1] from Maragliano's clinic at Genoa calls attention to the constancy of a great increase in the number of red corpuscles in case of a small, rather torpid tuberculous focus somewhere in the body These findings suggested the possibility that the minute amounts of antibodies generated in the course of such an inactive process, might be the cause of the hyperglobulia observed This assumption was sustained by the constantly positive findings when guinea-pigs were injected with small, repeated doses of tuberculin the result invariably being a pronounced hyperglobulia These findings further suggested in turn the possible application of the measure in treatment of all kinds of anemia and chlorosis, not necessarily of a tuberculous character Tuberculin in the minute "refractory" doses employed is harmless and is being given a thorough trial now in the clinic, the results seem to be promising, although it is too early for a definite conclusion to be reached The subjects are patients with blood impoverished from any cause Hyperglobulia may co-exist with pallor which is probably the reason why so little attention has been paid to the hyperglobulia of incipient tuberculosis or it may be due to the fact that by the time the patient reaches the physician this early stage of hyperglobulia may be past The induced hyperglobulia may be one of the factors co-operating in the benefit that has followed tuberculin treatment of tuberculosis Swan's article on the "Blood in Tuberculosis," in THE JOURNAL March 12, 1904 is cited in the communication but Swan's patients had passed beyond the phase of a merely torpid focus

CONTRACT PRACTICE

From time to time THE JOURNAL has editorially called the attention of its readers to the evils of contract practice and the need of eternal vigilance on the part of the profession to prevent the installation of a condition of affairs in this country similar to those existing in other lands like Great Britain Germany and Australia It has seemed to us at times that the medical press in this country was not sufficiently alive to these evils which have already appeared in some sections In a recent issue of the *New York Medical Journal* Dr Burnside Foster of St Paul calls attention to the need of action on the part of the profession, and points out the dangers from already existing contract practice in certain parts of the country Dr Foster shows that the remedy for the condition rests with the profession itself, and that only by its united action can its own further exploitation be stayed We need not here repeat the arguments against this form of practice, they should suggest themselves to every thinking physician We have the advantage of the experience of our brethren in other countries, and it would be a pity if we should have to learn in the same hard school Inaction on our part, however, will inevitably lead to this result Every form of contract practice proposed or already existing should have the most rigid scrutiny of the profession When cabinet ministers, as is alleged is the case in Australia, take advantage of membership in so-called benevolent societies to sweat the medical profession, we can see how far the evil may progress There is need of some addition to the published ethical principles as regards this point, and it is a good sign that in Minnesota and in a few other states they are already alive to the situation

OPTIMISTIC PROPHESYING

We are somewhat accustomed to optimistic statements in medical literature The advances in medicine have been so marked in late years that it seems rational to some people to anticipate in the near future results that a few years since would have seemed impossible, if not miraculous Thus we hear the extermination of tuberculosis confidently foretold, and some are even ready to prophesy that all disease and physical afflictions, excepting surgical accidents, will be abolished by the triumphant advance of medical science One of the latest of these prophets, in Great Britain, is reported to have claimed that all infection will be done away with, all noxious bacteria exterminated, and men in a hundred years from now will live a century, death being a sudden collapse from a painless exhaustion of the organs Even "a general flavor of mild decay," which would be due to the continued action of hostile bacteria is apparently not included in his consideration of the subject We can admit that a great deal has been done toward conquering disease, and that some of the most formidable scourges of mankind have been robbed of their terrors, and that the advance of medicine along this line still continues We must remember, however, that death and decay are as natural laws as birth and growth and that with all our knowledge of the causes of disease and its prevention, there yet remain many lacunæ Some diseases are conquered, others seem likely to conquer us It is not long since that a leading surgeon pointed out that at the present rate of increase of cancer mortality it would soon be the prevalent cause of death, at least in certain sections of the country This is not a pleasant prospect, and there are other disorders of which similar things may be said Our discovery of the microbe of a disease does not necessarily insure our ability to prevent or conquer it Pfeiffer's bacillus is hardly if at all less malignant at the present time than it was when grip first became epidemic Diseases of the heart and nervous system show few or no signs of decrease and new disorders appear from time to time We would not discourage a rational optimism but a reasoned apprehension of possible evils is safer than rainbow chasing in medicine at least is a guide to conduct Certainly it is far better than any reliance on presumptious prophesyings, no matter by what high authority Our profession will not be out of business for some time yet

---

Medical News.

CONNECTICUT

Medical Examiner—Dr D Chester Brown, Danbury, has been appointed medical examiner of Sherman, vice Dr John N Woodruff, Sherman, deceased

Home and Abroad—Dr Thomas H Welden, first selectman of South Manchester, returned from Europe, August 22 ——Dr Anthony J Hill, Torrington, sailed for Queenstown August 25 ——Drs Edward M McCabe and Stephen J Maher New Haven sailed for Germany, September 1

Infectious Morbidity—During July the State Board of Health received reports of 103 cases of measles in 26 localities 65 of scarlet fever, in 22 localities, 5 of cerebrospinal fever in 3 localities, 63 of diphtheria, in 25 localities, 31 of whooping cough in 9 localities, 61 of typhoid fever in 26 localities and 27 of consumption in 17 localities

July Mortality—The total reported mortality for July was 1 405 276 more than for the previous month 9 less than for July, 1903, and 6 less than the July average for the five preceding years The mortality was at the annual rate of 17 6 per 1,000, and 32 per cent or 450 deaths were due to infectious diseases Nervous diseases caused 133 deaths, violence 102 consumption, 100, heart disease, 99 and pneumonia 38

ILLINOIS

Peru Man Not a Leper—A conclave of Peru and La Salle physicians, aided by an expert from Chicago, has decided that Mathew Nubraski, supposed to be suffering from leprosy, was suffering from a skin disease of an entirely different nature

Fined, But Escapes.—Father Anseline, the so called "Quaker doctor,' who has been vending patent medicine in Moline, and was charged with practicing medicine without a state license was found guilty and sentenced to pay a fine of $100 and costs The defendant took the precaution to cross into Iowa before the verdict was announced

Milk Sickness Reappears—The State Board of Health on account of the reappearance after a lapse of many years, of what used to be known as milk sickness," and was supposed to be contracted by drinking the milk or eating the flesh of cows that had the "staggers," is continuing a study of the disease, and is accumulating information regarding it from the four counties in which it has appeared Four of the cases have proved fatal

Personal.—Drs James L. Taylor and B Barret Griffith have been appointed members of the Springfield Board of Health ——Dr Frank R. Wheeler, Auburn, is seriously ill from overwork, and has gone to Denver ——Dr Charles N Palmer, Clyde, was robbed of $180, while leaving an excursion steamer in Chicago ——Dr John N Nelms, Taylorsville was thrown from a bicycle, August 27, fracturing his right malar bone and bruising his head and shoulders

Chicago

Money for St Luke's.—By the will of Mrs J H McVicker $10,000 is devised to St Luke's Hospital

Deaths of the Week.—During the week ended September 3 491 deaths were reported, 10 more than in the previous week, an annual mortality rate of 13 27 per 1,000 Violence caused 69 deaths, acute intestinal diseases, 86, consumption 61, and heart diseases, 32

Hospital Dedicated.—The Washington Park Hospital, at 6010 Vincennes Avenue, was formally dedicated, September 5 Dr Carl O Young is chief of staff, and the staff includes Drs John B Murphy, Frank Billings, Archibald Church, William A Evans and Alfred Hakanson

August Mortality—The annual death rate for August was 12 93 per 1,000, 18 6 per cent lower than the average rate of the past decade The most important decreases were in deaths of children under 5, and especially in the contagious diseases of childhood, and in impure water diseases The principal cause of death was acute intestinal disease, with 467 deaths, consumption caused 256 deaths, Bright's disease 125 and pneumonia, 116

Statistics of the Summer Quarter—There were 5,820 deaths in June, July and August, equivalent to an annual mortality of 11 95 per 1,000 This is a reduction of 15 6 per cent, as compared with the summer quarter of 1903 The greatest reduction, 502, was among those under 5 years of age—a decrease of nearly 22 per cent Among the important causes of death showing an increase were Apoplexy, 5, Bright's disease, 21, consumption, 32, suicide 13, and other forms of violence, 33 Among those showing a decrease were—the acute intestinal diseases, 168, bronchitis, 60, cancer, 11 convulsions, 24, diphtheria, 59, heart diseases, 13, measles, 52, nervous diseases, 167, pneumonia, 150, typhoid fever, 29, scarlet fever, 48 smallpox, 6 sunstroke 20, and whooping cough, 9

INDIANA

Kokomo Hospital Gets Farm.—Mrs Anna Cage, Kokomo, who died recently, bequeathed a farm valued at several thousand dollars to the Kokomo Hospital Association

Smallpox.—Ten additional cases, with two deaths, are reported from Goshen The spread is charged to the negligence of physicians who diagnosed the disease as varicella

Fined for Illegal Practice—At the instance of the State Board of Medical Registration, Le Roy Rogers, Kewana, who held a license prior to the passage of the present law, but failed to have it renewed, was prosecuted, found guilty, and fined

Personal.—Dr John W Younge, Fort Wayne, has returned from the Holy Land ——Dr John N Hurty, Indianapolis, has been appointed a member of the committee of awards in the Medical and Hygienic Department of the Louisiana Purchase Exposition ——Dr Warren R. King, Greenfield, has been elected surgeon general of the Grand Army of the Republic ——Dr Andrew J Chittick Burlington, is seriously ill from septicemia

IOWA.

Waverly Hospital Dedicated—The new hospital presented to Waverly by Abraham Slimmer, was formally dedicated August 28

Culture Stations To Be Established—Culture stations for the investigation of contagious infections and transmissible diseases were expected to be ready for work September 1 The appropriation of $5,000 makes it possible at first to undertake only the diagnosis of diphtheria, typhoid fever, tuberculosis and rabies Examinations are made at the state university, free of charge

Must Furnish Statistics—The new law regulating the gathering of vital statistics which will be in effect as soon as the blanks are available, provides that all births and deaths shall be reported to the local health officers The law does not provide for payment for such reports, and there is a strong undercurrent of opposition among the profession, which thinks that the state should pay for work done

Faculty Changes—Dr Thomas J Maxwell, Keokuk, has resigned the chair of surgery in the Keokuk Medical College, College of Physicians and Surgeons, and Dr Charles E Ruth has been elected to fill the chair Dr John R. Maxwell succeeds Dr Ruth as professor of anatomy ——Drs Paul Shewkana, London, and Aufin Egdahl of Johns Hopkins, have been named as instructors in bacteriology and pathology in the University of Iowa

Medical Staff Assigned.—The following assignments of medical officers have been made For duty with Fifty fifth Infantry—Major J Fred Clarke, Fairfield, surgeon, Capt Wilbur S Conkling, Des Moines, and Capt Elliot R. King, Arion, assistant surgeons For duty with Fifty sixth Infantry—Major Donald Macrae Jr, Council Bluffs, surgeon, Lieut Pierre McDermid, Fontanelle, assistant surgeon For duty with Fifty third Infantry—Major Charles S Grant, Riverside, surgeon; Capt E L. Martindale, Clinton, and Lieut John C Hancock, Dubuque, assistant surgeons For duty with Fifty fourth Infantry—Major D S Fairchild, Jr Clinton, surgeon, Capt David A. Jay, Eldon and Lieut Albert B Deering Boone, assistant surgeons

KANSAS

Kills Assailant.—Dr E P Chace, Shawnee shot and killed John Cahill, who attacked him, after threats to kill

School Buildings Fumigated—The sanitary officer of Leavenworth has fumigated all the school buildings in the city in order that they may be in the best possible sanitary condition when school opens on September 9

Smallpox and Scarlet Fever—During the last quarter there were 299 cases of scarlet fever and 226 cases of smallpox in the state Saline County led in smallpox cases, with 35 cases, Labette and Cherokee counties having each 31 Barton County had 59 cases of scarlet fever, and Jefferson County 40 cases

New State Board—The governor, on August 29, announced the following appointments to the State Board of Health Dr G F Locke, Holton, reappointed, Dr Herbert M Bentley, Sterling vice Dr John M Minick, Wichita, deceased, Dr Charles Lowry, Topeka vice Dr Abraham S Gish, Abilene, Dr B J Alexander, Hiawatha reappointed and Dr Joseph B Carver, Fort Scott reappointed

MARYLAND

Faculty Meets—The semi annual meeting of the Medical and Chirurgical Faculty of Maryland will be held at Ocean City, September 9 and 10

Supplies Hospital Corps for Maneuvers—As the First Maryland Regiment has no hospital corps a detail will be sent to Manassas for it from the Fifth Maryland, under Capt S Griffith Davis, assistant surgeon of the latter regiment

New Building for Asylum—A new building will be added to the group at Spring Grove Asylum for the Insane, near Catonsville, the work on which will begin October 1 It will contain administration rooms, apartments for nurses and patients operating rooms and hydrotherapeutic plant A training school will be established for men and women nurses

Baltimore

Typhoid in August—There were 29 deaths from typhoid fever in August, and 207 new cases were reported, against 146 in August, 1903

Bequest to Hospital for Nurses—By the will of Mrs Anna M Gill of Paradise, Baltimore County $4,000 was devised to the trustees of the Johns Hopkins Hospital, to be used for the benefit of the nurses of that institution

Insane Removed.—On August 31 forty patients were removed from the insane department of Bayview Asylum—the city almshouse—to Springfield Asylum for the Insane Sykesville to relieve the congestion in the former institution

Crim Bequest Valid—The Crim bequest has been declared valid in the courts By the will of the wife of the late Dr William H Crim the University of Maryland School of Medicine was bequeathed about $40 000 to found a William H Crim professorship

Personal—Dr Delano S Fitzgerald is at Manhattan Beach, N Y——Dr Harry T Marshall has been elected pathologist at the Baltimore Medical College, vice Dr T Robert W Wilson resigned, to devote himself to private practice.——Dr Stewart Paton will spend the winter abroad——Dr Augustus G Pohlman has resigned his instructorship in anatomy at Johns Hopkins University to accept an appointment as assistant professor of anatomy in the University of Indiana, Bloomington

New House Staff—The following graduates of last June entered on their duties on the house staff of the Johns Hopkins Hospital August 31 John Herbert Carr, Josephine Hemenway, Julius A Caldwell, Jr, Jewett Villewy Reed, Ernest Sachs, Walter V Brem, Jr, Wilfred H Mainwaring, Herbert Ziegler Griffin, Orville Hickok Schell Harry S Greenbaum, Robert G Washburn, Herman W Marshall, Benjamin T Terry, Robert Bennett Bean, G Lane Taneyhill, Jr, William J Ricker, Charles M Remsen, Maurice Buford Bonta, De Witt B Casler, and James F Morrison

New Surgical Building Dedicated—The new surgical building at the Johns Hopkins Hospital will be dedicated October 5 The program will consist of addresses by several prominent American and foreign physicians, and a large number of eminent medical men, including those gathered at St Louis this month, will be invited to attend After dedication it will be inspected and a luncheon will be served In the afternoon a bronze tablet erected to the memory of Dr Jesse W Lazear, who lost his life from yellow fever in Cuba while investigating that disease there in 1900, will be dedicated in one of the amphitheaters The building cost about $150 000, is of brick, and four stories high Sanitation and ventilation are important features All the floors are of tiles, every room and hallway used by patients being also wainscoted with glazed white tiles The stairways are of marble and iron, and there are toilet rooms and baths on each floor A surgical amphitheater, 40 feet high, also has extensive tiling marble work, and a hall with wide lights composed entirely of wired glass There are a number of consultation rooms On the first floor will be emergency rooms for accident cases, minor operation rooms, and the orthopedic department Two large vaults of brick and cement are provided for surgical records

NEW JERSEY

Bequest to New York Academy—The late Dr Albert W Warden of Union Hill, West Hoboken, in his will, bequeathed $1,000 to the New York Academy of Medicine

Personal—Dr Theodore G Davis, Bridgeton, left, September 6, for California, where he will spend the winter——Dr William H Westcott, Berlin, was painfully injured by a collision with an automobile, September 2

Staff for Sister's Hospital—The hospital committee of the new Sister's Hospital, Elizabeth, has appointed the following staff Drs John P Reilly, Victor Mravlag, Stephen T Quinn Thomas E Dolan, and James S Green

Fighting Glanders—The State Board of Health and the Jersey City Board of Health are endeavoring to stop the importation into the state of glandered horses Last week five horses suffering from this disease were discovered in Hudson County

New Hospital for Orange—Buildings and grounds have been purchased for the establishment of a new hospital in Orange The hospital will be equipped as soon as possible, and will be opened about November 1 It will have about thirty beds besides a maternity ward and children's wards The institution is to be known as Mount Carmel Hospital and will be nonsectarian

NEW YORK

Buffalo

Parmenter Resigns—Dr John Parmenter has resigned the chair of anatomy and the secretaryship of the faculty of the medical department of the University of Buffalo, retaining, however, the professorship of clinical surgery Dr Herbert U Williams has been promoted from the associate to the governing faculty, and retains the title of professor of pathology and bacteriology Dr Herbert M Hill has been appointed secretary of the faculty

Personal—Dr Grover Wende has sailed on the *Deutschland* to attend the International Dermatological Congress in Berlin——Dr Frank W Hinckel has returned from Europe, where he went as delegate to the International Otological congress at Bordeaux——Dr W Scott Renner is soon expected home from his trip abroad——Dr Marshall Clinton has returned from the Adirondacks——Dr David Wheeler has gone to the Adirondacks——Dr Irving W Potter and Dr George A Himmelsback have returned from Europe——Dr Edward Clark, assistant health commissioner, is convalescing from his recent attack of multiple neuritis

New York City

Department of Health Needs More—The health department has sent to the board of estimate a request for $2,123,500 for its 1905 allowance, an increase of $577,656 52 over the 1904 allowance

Smallpox on Liner—On account of a case of smallpox on the *Campania*, she was detained over night at quarantine, the patient was transferred to the Kingston Avenue Hospital, Brooklyn, and 26 passengers were sent to Hoffman Island for observation

Personal—Dr L Duncan Bulkley sailed for Bremen August 30——Dr McGeary, ambulance surgeon at St Vincent's Hospital, had a narrow escape from serious injury while riding on the ambulance when it collided with a trolley car——In a collision between a trolley car and his carriage, Dr Martin W Auspitz fractured an arm and a leg, and his carriage was demolished

Contagious Diseases.—In the week ended August 27 there were reported to the sanitary bureau 371 cases of tuberculosis with 147 deaths, 244 cases of diphtheria, with 25 deaths, 140 cases of typhoid fever with 27 deaths, 70 cases of measles, with 4 deaths, 48 cases of scarlet fever, with 2 deaths, 3 cases of varicella and 17 deaths from cerebrospinal meningitis

Hospital Notes—William H Crawford bequeathed $10,000 to the New Amsterdam Eye and Ear Hospital——Efforts are being made to raise funds for the reopening of the pavilion for contagious eye diseases of the Eye and Ear Infirmary, which has been closed since March 1 ——The new Beth Israel Hospital is to be enlarged by the remodeling of a six story tenement house near by, to which it will be connected by bridges ——All the city hospitals are so crowded that the authorities view the approach of winter with much apprehension The public hospital accommodations of this city are totally inadequate

More Typhoid.—According to the recent canvass made among private physicians there are now more than two hundred cases of typhoid fever in the Bronx Such a large number is causing Bellevue and the allied hospitals great trouble because of the present crowded condition of these institutions Dr Gregory has ordered the erection of a temporary hospital on the grounds of the Fordam Hospital, which will provide for about a dozen typhoid patients The cases are scattered and due to local contaminations, and, therefore, the health department is not alarmed and does not fear a general epidemic

PENNSYLVANIA.

Good Results.—Oliver B Simmons in charge of the South Mountain Camp Sanatorium for the care of consumptives on the state forestry reservation at Mont Alto, reports that since the opening of the sanatorium in June, 1903, 65 patients have been received, and that of this number 50 per cent have returned to their homes apparently totally cured and 33 patients are still under observation in the sanatorium These statistics are practically in accord with those reported from the White Haven Sanatorium

Philadelphia.

Personal.—Dr and Mrs Peter N K Schwenk have returned from a trip in Europe

Bequest to Episcopal Hospital.—By the will of the late J Lower Welsh, the Hospital of the Protestant Episcopal Church receives $50,000

One Year's Work in the Municipal Hospital.—During 1903 3,399 patients were treated in the institution, and 3,204 were admitted, 2,464 were discharged, and 512 died The number remaining at the end of the year was 423 The general death rate for the entire hospital was 17 20 per 1,000

Maragliano Serum at Phipps Institute—A thorough test of the Maragliano serum in the prevention and cure of tuberculosis is to be given at the Phipps Institute Patients have been selected on whom the serum will be faithfully employed. In connection with the use of the serum, it is advised that the patients eat, as part of their food, meat from cattle rendered immune by the administration of the serum

Malaria-Breeding Mosquitoes at Navy Yard.—The malaria breeding mosquito has recently been discovered at League Island, and its presence has led the authorities to seek its breeding place and stamp it out During the past year the men at the island have been remarkably free from malaria, only two or three cases having occurred This is said to be due to the efforts of the authorities to exterminate the mosquito by the free use of kerosene on the stagnant pools which surround the yard. It is asserted that the dangerous species of mosquito is a new arrival, and that its breeding place lies in the marshes outside the navy yard grounds

Health Report.—Typhoid fever shows a steady increase since August 1, and only seven wards in the city are free from the disease During last week 104 new cases were reported, with 10 deaths as compared with 87 new cases and 8 deaths for the preceding seven days In all there were 178 cases of contagious disease, with 14 deaths During the preceding week there were 157 cases, with 12 deaths The general death rate is below normal, and the deaths from all causes numbered 371, a decrease of 51 from those of last week, and an increase of 17 over the corresponding period of last year

TENNESSEE

Will Build Hospital—Tennessee Medical College Knoxville, will erect a hospital to cost $25,000, and to accommodate 55 patients

Smallpox.—Russellville, Hamblen County, reports 7 cases ——Between Lyles and Bear Creek, Hickman County, there are from 50 to 75 cases, and compulsory vaccination has been ordered —Seven cases are reported from Jasper, Marion County ——A new case has developed in Spring Creek, Perry County, and the schools have been closed

Personal.—Dr William Litterer has been made professor of histology, pathology and bacteriology in the medical department of Vanderbilt University Nashville vice Dr Louis Leroy resigned ——Dr Reuben S Stanley, Memphis, was thrown from his buggy in a runaway accident August 24, sprained his wrist and sustained serious internal injuries

GENERAL

Society for the Study of Alcohol.—The American Medical Society for the Study of Alcohol and Other Narcotics was organized, June 8, 1904, by the union of the American Association for the Study of Inebriety and the American Medical Temperance Association The alcoholic problem and the diseases which spring from it are becoming more prominent and its medical hygienic importance have assumed such proportions that physicians everywhere are called on for advice and counsel All physicians are asked to assist in making this society the medium and authority for the scientific study of the subject, and the secretary, Dr T D Crothers, Hartford Conn, will be pleased to give any further information

Testimonial to Dr Chapin.—It is proposed to give a dinner in November next, to Dr Chapin, superintendent and physician of the Pennsylvania Hospital for the Insane, who has just completed a half century's work in behalf of the insane He was appointed assistant physician at the State Lunatic Asylum, Utica, New York, in 1854 Afterward he became connected with the late Dr George Cook in the conduct of Brigham Hall Canandaigua, New York, and then, first as one of the building commissioners, and subsequently as physician and superintendent, with the Willard Asylum for the Chronic Insane, an institution made famous under his organization and work Since 1884 he has been the medical chief of the Pennsylvania Hospital for the Insane His friends have also arranged to have his portrait painted for presentation to him and to his family in honor of the event Contributions from his friends may be sent to Dr E N Brush, the Sheppard and Enoch Pratt Hospital, Towson, Md

FOREIGN

Relief Work at Harbin.—The receiving committee at Harbin had 7,901 sick and wounded arrive by train from the seat of war during the first month All but 437 were distributed in the hospitals of the Amur and neighboring regions, the rest being sent home to Russia

Red Cross Relief for Psychoses Among the Soldiers—As mentioned recently, page 680, the number of psychoses in the Russian active forces is very large, especially among the officers of the troops at the front The Russian Red Cross has established a central station for such patients at Harbin

Traffic in Sales of Medical Practice.—A certain Dr Lawson of England was sued for misrepresentation of the facts in the sale of a medical practice The courts condemned him to damages and costs The remarkable feature of the case was the discovery that this was the twenty ninth or thirtieth transaction for the sale of a medical practice in which he had engaged

Etiology of Malaria.—A few Greek writers are dubious in regard to the mosquito origin of malarial infection They claim that the disease is liable to appear for the first time during the months of the year when there are no mosquitoes They think that emanations from the soil, stagnant water, etc, are possible factors in its origin, Cardamatis asking "If the infection of man necessarily precedes that of the mosquito, whence did man derive his primary infection in the first place?"

Cholera in Russia.—Our Russian exchanges have been commenting on the threatening epidemic of cholera in Persia, and a large medical force was dispatched to the frontier to prevent the importation of the disease into Russia The latest advices by mail are that the epidemic is declining, and that only a single suspicious case was noted in Southern Russia The cable now brings word that several cases of cholera have been discovered in St Petersburg and that there is great alarm

Thermometer That Can Be Boiled—Bardy's clinical thermometer is made with a bulb above, which allows the mercury to expand without injury to the thermometer when it is boiled The mercury can be readily restored to its place by a simple maneuver Professor Raymond recently presented it with a high eulogy to the Paris Académie de Médecine, stating that its use puts an end to the fear of transmission of infection by means of the thermometer Kantorowicz of Berlin has invented a similar thermometer, mentioned on page 1112 of the last volume

Sale of a Medical Practice—The widow of a French physician sold her late husband's practice, office, books, instruments, etc, to another physician, who signed the contract in due *form* He afterward found another more promising chance and declined to fulfill the contract claiming that the sale of a medical practice is not legal The local court sustained him in this view, but the court of appeals awarded the widow the damages claimed, on the ground that the articles mentioned in the contract, the location, books, and agreement to introduce the newcomer, represented negotiable property on which a contract was binding

The School in the Woods for Sickly City Children —A new departure in school hygiene has been inaugurated at Charlottenburg, Germany A day school has been established in a pine forest outside the city limits and the children and teachers go there in the early morning and return home in the evening About 120 anemic and weakly children were selected from the various day schools and transferred to this new establishment Arrangements are made to feed the children and to give them medical oversight Only two and a half hours are devoted to school tasks, the rest of the time the children play in the woods or pavilion Dr Bernhard Bendix is the physician in charge of the institution, the official name of which is the Waldschule für kränkliche Kinder

The Approaching International Medical Congress. —The committee of organization of the Lisbon congress is issuing a bulletin from time to time which displays such businesslike methods and devotion to science that it augurs well for the success of the congress Nos 2 and 3 have been recently received They contain the list of the subjects of the official reports, with the names and addresses of the authors A list of subjects recommended as themes for further communications in each section are given The national committees and names of enrolled members are also published A colonial exposition is to be one of the features of the meeting as also the conclusions from a collective inquiry on pellagra The Americans have not sent in their names promptly, only one being found as yet on the list of official addresses—Dr W J Morton of New York, who will speak on the “Ultra Microscope” Among the “recommended subjects” in the section of medicine, we note Colibacillosis” “Dyspnea in Acute Febrile Diseases”, “Meningeal Hemorrhages”, “Paralysis in General, Etiology and Treatment,” and “Headaches” Twenty eight themes are recommended in the section of neurology and psychiatry and thirteen in obstetrics and gynecology Among the addresses in the latter will be one by Pinard on “Gravidal Autointoxications” Sixteen themes are suggested for the section of hygiene, among them being “Means to Combat Grippe,” Street Sprinkling,” and “Epidemiology of Cerebrospinal Meningitis” The list of participants already reads like a roster of the chief luminaries of European science The secretary asks that articles be forwarded to him before Sept 30, 1905, typewritten if possible, to facilitate prompt printing All correspondence should be addressed to Prof Miguel Bombarda, Hopital de Rilhafolles Lisbon See page 141

LONDON LETTER

Vital Statistics in 1902

The sixty fifth annual report of the registrar general dealing with the births, deaths and marriages in England and Wales in 1902 has just been published The estimated population in the middle of 1902 amounted to 32,997,626, of whom 15,952,154 were males and 17,045,742 females The marriage rate was 15 9 per 1,000 of the estimated population of all ages, which showed a slight increase, in the 3 year periods of 1880 1882, 1890 1892 and 1900 1902 it being 15 2, 15 5 and 15 9 respectively But as a large majority of the population are either already married or are below the age at which marriage takes place, the total population is not a satisfactory standard by which to measure the rate of marriage If it be calculated on the unmarried and widowed portion of the population above the age of 15, the apparent increase is turned into a decrease, for the rates for the same periods on this basis are 51 5, 49 8 and 48 7 The birth rate during the year was 28 5 per 1,000, which was identical with that of 1901, but was 1 1 per 1,000 below that of the decade 1892 1901 The death rate was only 16 2 the lowest on record since civil registration was established in 1837

Statistics of Infectious Diseases in London in 1903

The annual report of the Metropolitan Asylums Board, in whose hospitals most of the cases of fever occurring in London are treated, show in 1903 a death rate for scarlet fever of 3 1 per cent , for diphtheria, 9 6 per cent , for typhoid fever, 15 3 per cent , for typhus fever, 21 per cent , and for smallpox, 3 3 per cent The number of cases of infectious disease admissible to the board's hospitals and classified as such was, in 1901 35,311, in 1902, 40,046, in 1903, 23,087 For this falling off the abatement of the recent smallpox epidemic was largely responsible, the number of cases of the disease being, in 1901 1,700, in 1902, 7,796, in 1903, 416 Other diseases also show a considerable decline Thus, the number of cases of scarlet fever in the 3 years was 18,381, 18,252 and 12,531 respectively of diphtheria, 11,068, 10,538 and 7,582, of typhoid fever, 3,194 3,407 and 2,339 In typhus fever alone was there an increase to 22, the highest number since 1893 With regard to diphtheria an encouraging feature of more importance than the small number of cases is the continued decrease in the rate of mortality since the introduction of the antitoxin treatment Before this the mortality varied from between 30 and 40 per cent In 1895, the year in which the antitoxin treatment was introduced, it fell to 22 8 In 1903 it was only 9 69 per cent , though many cases are brought to the hospital too late for treatment The figures showing the day of the disease on which the treatment was first used are even more striking At the Brook Hospital, between 1897 and 1903, 187 cases were treated with antitoxin on the first day of the disease without a single death 1,186 on the second day, with 5 4 and 5 per cent deaths in the first 2 years of the series respectively, since which the rate has been about 4 per cent In cases treated after the second day the mortality is much higher, ranging up to and sometimes exceeding 20 per cent An adverse report is made on Finsen's treatment of smallpox by excluding all but red light He claims that suppuration of the vesicles and pitting are prevented, that suppurative fever is abolished, and that the mortality is lowered No such effects were observed in a small ward in which the treatment was carried out, and, moreover, the gloom was believed to have a deleterious influence on the general condition of the patients

Physical Degeneration

For some time the public has been gravely concerned by the alleged physical degeneration of the population, which is a standing topic of discussion both in the lay and medical press Like a good many other topics which furnish "copy" for the press, the subject has sprung into prominence simply because of the sensationalism aroused, and not because it rested on any real basis of fact The question became so burning that the government took it up and appointed a committee "to make a preliminary inquiry into the allegations concerning the deterioration of certain classes of the population as shown by the large percentage of rejections for physical reasons of recruits for the army and by other evidence, and to consider by what manner the medical profession can best be consulted on the subject with view to the appointment of a royal commission The committee has now issued a report They are unable to discover any trustworthy evidence of the general or extensive physical degeneration which has been supposed by some to exist They recommend that, 1, an anthropometric survey be made with a view to the collection of definite data bearing on the physical condition of the population, in the first instance periodic measurements of children in schools might be taken 2 That a register of sickness not confined to infectious diseases should be established 3 That an advisory council containing members appointed by the medical corporations be formed to receive the reports and advise the government Such a council might be modelled to some extent on *Le Comité Consultatif d'hygiène publique* in France 4 That the problem of overcrowding be drastically dealt with by fixing a standard beyond which crowding will not be allowed 5 The provision of labor colonies and public nurseries Further recommendations are made which involve almost every department of hygiene such as smoke pollution, medical inspection of factories, alcoholism, food and cookery, employment of women, milk supply feeding of infants exercises for children open spaces

---

Correspondence.

Evidently

Charleston, Ill., Sept 3, 1904

To the Editor —I notice in The Journal for August 27 that Dr W W Keen, in a letter apropos of the educational exhibit at St Louis, has this to say "Next to Germany Japan has done the most What she is doing in war she is doing in medicine" Permit me to remark that, if Japan is doing in medicine what she is doing in war, she must, indeed be playing hades with her sick

Yours sincerely,

T H Shastid

A Loose Standard of Measurement.

TOLEDO OHIO, Sept 3, 1904

To the Editor —In THE JOURNAL for September 4 a writer says that a tumor was "about the size of the distal phalanx of an adult finger," and in the next paragraph he says a gland was "about the size of a marrowfat pea" I presume in the first instance that he refers to the finger as you see it and not to the bone, because in somewhat awkward English he seems to say that the tumor was 5 cm in length and 3½ cm in breadth It is quite likely that when boys the most of us helped to grow peas, but it is just as likely that the physician who now refers you to a marrowfat pea does so from boyhood memory, and for the last twenty years has not been able to tell one variety of pea from another 'Two feet—the length of the hammer handle—and so much' is an old time expression for the happy go lucky measurements as made by the journeyman carpenter, and "bean sized," "pea sized" "nut sized" "fingernail sized" skin eruptions, tumors, etc, convey about the same ideas of exactness It is quite as easy to think of fractional parts of an inch or of a centimeter as of the average size of adult fingers

URINARY EXAMINATION IN LIFE INSURANCE WORK

DR. WILLIAM D BYRNE Chicago writes In the routine work of urinary analysis connected with examinations for life insurance it is customary to scrutinize the specific gravity and the reaction and to make the heat and nitric acid tests then if these show abnormalities a microscopic examination for casts follows Now in the early stages of interstitial nephritis do we not find heart and arterial changes as also alterations in the percentage of urea of greater value in determining a correct diagnosis? The text books do not elucidate this satisfactorily and I should like to hear from you if you can give the time to answering me

ANSWER.—Ordinarily the early stage of chronic interstitial nephritis is marked by an increase of the 24-hour amount of urine of which the urine of the night is notably greater than that of the day The specific gravity of the total 24 hour urine is relatively low the percentage and total urea is also less than normal The blood pressure is increased and may be noted by instruments but may not be perceptible to the fingers. In the early stage the cardiovascular changes which are so easily recognized later may not be perceptible Even in the early stage the microscope may enable one to detect hyaline and even finely granular casts and especially if a centrifuge be used to sediment the urine Therefore the important points in the recognition of chronic interstitial nephritis in the early stage are the increase of urine for 24 hours of which the night excretion exceeds that of the day relatively low specific gravity relative and total decrease of urea increase of blood pressure the presence of hyaline and often of granular casts and the presence often in the urine of a trace of albumin

---

SAN FRANCISCO Aug 29 1904

To the Editor —Will you kindly inform me what states have no medical law

R F T

ANSWER.—None of the states and territories in the Union is without a medical law at the present time except Alaska

Book Notices.

PHYSIOLOGY AND PATHOLOGY OF THE URINE with Methods for Its Examination By J Dixon Mann M D F R.C P Physician to the Salford Royal Hospital With Illustrations Cloth Pp 272 Price, $3 00 London Charles Griffith & Co Ltd Philadelphia J B Lippincott Co 1904

Dr Mann takes up the subject of the physiologic and pathologic constituents of the urine and the usual chemical and microscopic tests, with a brief consideration of certain diseases in which the urine plays an important part. The subject is well handled, but the author does not depart materially from the methods of writers on this subject who have preceded him

CLEFT PALATE AND HARELIP The Earlier Operation on the Palate. By Edmund Owen, M B F R.C S Surgeon in Chief to the French Hospital Cloth Pp 111 Price $1 00 net Chicago W T Keener & Co 1904

This little monograph is devoted almost entirely to a description of the operative treatment of cleft palate after the method of Dr Truman W Brophy of Chicago Mr Owen is convinced, after practical experience, that this method marks a great advance in the surgery of the defect

INFECTIOUS DISEASES Their Etiology Diagnosis and Treatment By G H Roger Professor Extraordinary in the Faculty of Medicine of Paris, etc Translated by M S Gabriel M D New York With 43 Illustrations Pp 864 Cloth Price $5 75 net. Philadelphia and New York Lea Brothers & Co 1903

One can not peruse this work without recognizing at once that it has been written by a master mind The subject has been comprehensively covered in all its phases, historical, theoretical and practical, experimental and clinical The work of the laboratory is weighed and measured by the facts as presented at the bedside, the results of the one thus controlling and supplementing those of the other in a manner which could only be done by one not only perfectly familiar with laboratory and experimental methods, but also having at his command unlimited clinical facilities The work is an excellent one and of great value, not only to the general practitioner, but also to the surgeon and specialist, for there is no branch of medicine which does not have to reckon with this class of diseases

Marriages.

JUDSON A HULSE M D to Miss Hilda Inman, both of Akron Ohio

GEORGE L BOND, M D, Alto, Mich to Miss Georgianna Baker of Ridgeway, Mich

JOSEPH H DOYLE, M D, to Miss Lena Jansen, both of Little Chute, Wis, August 17

ROBERT WIENER, M D, to Miss Lillie Polowe, both of New York City, September 4

JOHN C COCHRAN, M.D, Big Run, Pa. to Miss Ruth Deri of Lancaster, Pa, July 20

DANIEL HOPKINSON, M.D, to Miss Manette Meinecke, both of Milwaukee, August 24

C T JONES, M.D, Stafford, Kan, to Miss Anna Harrison of Wichita, Kan, August 15

R. M BOLMAN, M D, Fort Wayne, Ind, to Miss Catherine Geiger of Bloomville, Ohio

ALBERT C MCCLANAHAN, M D, Chicago, to Miss Locky Fox of Portland, Ore, August 24

JAMES W GAGE, M D, Garrett, Ind, to Miss Mary Kruenpelbeck of Cincinnati, August 30

JAMES GORMLY, M D, Meadowlands, Pa, to Miss Elsie V Read of Vineland, N J, August 24

W E SHALLENBERGER, M D, Canton, Ill to Miss Kathryn Elsenfast, at Peoria, Ill, August 17

J M LANNING, M.D, Corinth, Miss, to Mrs Lydia B Van Anda of Manchester, Iowa, August 27

CHARLES P DOYLE, M D, Frankfort, Mich, to Miss Clara Kenney of Manistee, Mich, August 17

LEVI F DUCKETT, M D, Cloverdale, Ala, to Mrs Elizabeth Ashcraft Jones of Florence, Ala, August 11

JAMES A WRIGHT, M.D, to Miss Nellie Thompson, both of Fair Haven, Ill, at Clinton, Iowa, August 24

JOHN C SUNDBERG, M.D, Santa Cruz, Cal, to Miss Hermance Idalie Bundesen of San Francisco, August 18

WALTER CLARENCE BLEY, M.D, Beardstown, Ill, to Miss Pearl McDonald Barclay of Virginia, Ill, August 27

FREDERICK BARRETT, M.D, Eveleth, Minn, to Miss Edith Susan Smith of Beaver Dam, Wis, August 25

HENRI HARCOURT SUTCLIFFE, M D, to Miss Marion Elizabeth Thompson, both of San Francisco, Cal, August 20

WILLIAM HUBERT AARON, M D, Pawhuska, Okla, to Miss May Roxy Todd of Gray Horse, Okla, August 11

EDWARD MATTHIAS ZEH HAWKES, M D, Newark, N J, to Miss Mary Everett of Minneapolis, Minn, August 29

CHARLES PARKS, M.D, Atwood, W Va, to Miss Mona Langfitt of Morgansville, W Va, at Parkersburg W Va., August 24

HENRY SHACKELFORD KELLER, M D South McAlester I T, to Miss Helen Houston Beach of Louisville Ky, at South McAlester August 13

Deaths.

John Forney Zacharias, M D Jefferson Medical College, Philadelphia 1860, dropped dead in his drug store at Cumberland, Md, August 16, aged 63 He served as assistant surgeon in the Confederate Army from 1862 to 1865, and settled at Cumberland in 1871 During the war he employed maggots in the treatment of hospital gangrene to remove decayed tissue, and claimed that hereby he saved many lives escaped septicemia, and had rapid recoveries"

Henry Marshall Fenno, M D Harvard University Medical School, Boston, 1876, a member of the American Medical Association, New York State Medical Association, Monroe County Medical Society and Rochester Pathological Society city physician of Rochester, N Y from 1879 to 1881 died at his home in Rochester August 17 from malignant disease for which he underwent operation a year ago aged 53

Joseph Wiener, M D College of Physicians and Surgeons in the City of New York, 1874, a member of the Academy of Medicine, the German Medical Society, and the Physicians' Mutual Aid Association, for many years associate to the chair of military surgery in that institution, died at his home in New York City, August 11 from heart disease after a prolonged illness, aged 76

David C Murphy, M D College of Physicians and Surgeons Keokuk, Iowa, 1874, a member of the Kansas Medical Society died at his home in Edwardsville, Kan, August 22, aged 57 The Wyandotte County Medical Society, at a special meeting August 23, adopted resolutions regarding the death of Dr Murphy

Benjamin D Watkins, M D Tulane University of Louisiana, New Orleans, 1887, surgeon of the Y & M V and N O & N W railways, and once president of the State Board of Health, who was thrown from his buggy and injured, died at his home in Natchez Miss, as a result of the injuries, August 12

William J Lodge, M D University of Maryland School of Medicine, Baltimore, 1859, some time surgeon U S Navy but since his retirement from practice on account of ill health noted for his genealogic researches, died at his home in Baltimore, August 21, from Bright's disease, aged 72

James M Poyntz, M D University of Louisville, 1873, of Richmond Ky, county referee of Madison County, surgeon in the Confederate service during the Civil War, died at Mount Sterling, Ky, August 16, from consumption after an illness of three years, aged 67

Oscar Wiley, M D Medical Department of Randolph Macon College Prince Edward Court House, Va 1851, surgeon of the Fifty fourth Virginia Infantry, C S A, during the Civil War died at his home in Salem, Va, August 25 from angina pectoris, aged 73

Henry Tuck, M D Harvard University Medical School, Boston, 1867, of New York City, vice president and medical director of the New York Life Insurance Company, died, after a long illness, at his summer home in Seabright, N J September 2, aged 62

Henry J Warmuth, M D Rush Medical College, Chicago, 1868, of Smyrna, Tenn, died in Philadelphia from disease of the stomach, August 12 after an illness of two years, aged 70 He served as surgeon in the Confederate army during the Civil War

Isaac N Dalbey, M D Medical Department of Wooster University, Cleveland, 1868, who gave up practice ten years later to enter the pulpit, died at his home in Rochester, N Y, August 15, from malignant disease, after a prolonged illness, aged 58

James Herbert Hogue, M D College of Physicians and Surgeons of Baltimore, 1885 a member of the American Medical Association, the head of the Gynecean Hospital, Altoona, died at his home in that city August 30, from paralysis, aged 44

Charles Frederick Herman Willgohs, M D Rostock University, a veteran of the war of Polish Independence, died from pneumonia at the home of his daughter in Akron, Ohio, August 26, after a short illness, aged 100 years and 9 months

Charles L P Smith, M D Yale University Medical Department New Haven Conn, 1898 died at his home in Cornwall Bridge, Conn, August 18, from injuries received in being struck by a railway train three days before, aged 28

William D Spore, M D McDowell Medical College, St Louis 1861, of St Louis, died at the Mullanphy Hospital in that city, August 10, from kidney disease of long standing, for which an operation was performed, aged 63

Orlanda Chester Robinson, M D Department of Medicine of the University of Pennsylvania, Philadelphia, 1881, died at his home in Huntingdon Valley, Pa, August 4, from consumption after a lingering illness, aged 42

John S Hileman, M D Department of Medicine of the University of Pennsylvania, Philadelphia, 1889, died at his home in Pittston, Pa, August 6, three days after an operation for appendicitis, aged 40

Henry C Barnard, M D Medical Department of the University of Iowa at Keokuk, 1866, surgeon during the Civil War died at his home in Charleston, Ill, August 10, after a prolonged illness, aged 68

William O Griggs, M D University of Maryland School of Medicine Baltimore, 1893, of New York City, died at the home of his sister in Baltimore, August 26 from consumption aged 35

F Le Baron Monroe, M D Harvard University Medical School Boston, 1860 surgeon U S Army retired, of Meriden, N H died suddenly in Woburn, Mass, from apoplexy, August 14 aged 69

Claude R Wellington, M D Medical School of Maine at Bowdoin College, Brunswick, 1898 died at his home in Mansfield Mass August 18, from the effects of an overdose of chloral aged 34

Siva Carman, M D New York University, New York City 1881, of Seattle, Wash died at the Stellacoom Asylum, to which he had been committed in 1901, August 12, aged about 50

William E Boteler, M D University of Maryland School of Medicine Baltimore died suddenly at his home in Middletown Md, from fatty degeneration of the heart, August 14, aged 83

Myron D Blaine, M D Detroit Medical College, 1883, of Auburn, N Y, died at the Clifton Springs Sanitarium, Dansville, N Y, from rheumatism, after a long illness, aged 45

Edward A. H Purdon, M D Chattanooga (Tenn) Medical College, 1891, of Corinne, Utah died at the Ogden General Hospital, August 3, after an operation for abscess of the liver

Eldridge G Simons, M D Bellevue Hospital Medical College New York City, 1875, of Ripley, N Y, was struck by a train in Cleveland, Ohio, September 1, and instantly killed.

Arthur J Tessier, M D Baltimore (Md) Medical College 1901, died at his home in Somersworth, N H, August 19, from typhoid fever, after an illness of one week, aged 25

William M Tobey, M D, for 30 years a practitioner of New London, Conn, died at his home in that city, August 14, from paralysis after an invalidism of 12 years, aged 83

J Lewis Woodville, M D Department of Medicine of the University of Pennsylvania, Philadelphia, 1844, died at his home near Sweet Springs, W Va, August 14, aged 87

Charles T Quinn, M D Southern Medical College, Atlanta Ga, 1887, died at his home in Naylor, Ga, August 27, from typhoid fever, after an illness of ten days, aged 43

Hugh C McCord, M D College of Physicians and Surgeons in the city of New York, 1883, of New Haven, Conn, died at the New Haven Hospital, August 27, from apoplexy

Samuel H Guilbert, M D Ohio, 1857, of Dubuque, Iowa, died August 28, in Roosevelt Hospital, New York City, where he underwent operation, two weeks before, aged 69

John W Tiffany, M D Iowa, 1883, of Hiawatha, Kan, died at the home of his son in Cedar Rapids, Iowa, August 25, from disease of the liver, after a long illness, aged 62

William Ussery, M D University of Nashville, Tenn, 1894 died at his home near Lonevak, Montgomery County, Tenn August 29, after an illness of six weeks, aged 32

David McClean Crawford, M D New York University, New York City, 1851, state senator in 1870 and 1876, died at his home in Mifflintown, Pa, August 25, aged 78

Millard Fillmore Cyphers, M D Department of Medicine of the University of Pennsylvania, Philadelphia, 1887, died at his home in Philadelphia, August 29, aged 45

John Hector Mackay, M D College of Physicians and Surgeons in the City of New York, 1868, died at his home in Truro, N S, August 3, from acute nephritis

Daniel H Cole, M.D University of Michigan Department of Medicine and Surgery, Ann Arbor, 1852, died at his home in Memphis, Mich, August 10, aged 81

George Henry Fales, M D Harvard University Medical School, Boston, 1868, died at his home in East Boston, Mass, August 8, from cerebral hemorrhage, aged 62

Charles B Weida, M.D Jefferson Medical College, Philadelphia, 1887, died at his home in Braddock, Pa, August 29, from morphin poisoning, aged 37

John P James, M.D University of Nashville (Tenn) Medical Department, 1861, died at his home near Gibson, Tenn, August 14, after a long illness, aged 73

George Henry Dayton, M D New York University, New York City, 1846, died recently, and was buried at his old home in Lima, Ind., August 14, aged 80

Gideon D Harris, M D Tulane University of Louisiana, New Orleans, 1899, of Indianola, Miss, committed suicide, August 30, by severing the femoral artery

Anderson G Cross, M.D Jefferson Medical College, Philadelphia, 1857, died at his home in Waynesburg Pa, August 23, after a long illness, aged 83

William Thompson, M D University of Edinburgh, Scotland, 1855, of Pittsburg, Pa, died in Weehawken, N J, August 21, after a short illness, aged 75

Russell C Barrett, M D Toledo (Ohio) Medical College, 1886, died at his home in Toledo recently, and was buried at Wauseon Ohio, August 26, aged 70

Jacob S Whitman, M.D Jefferson Medical College, Philadelphia, died at his home in Lyndon, Kan, August 12, after an illness of several months

Carl Bergk, M D University of Gottingen, Germany, 1867, died at his home in Bloomingdale, Fort Wayne, Ind, August 27, from diabetes, aged 60

Robert J Jackson, M.D Missouri Medical College, St Louis 1870, died at his home in Bloomfield, Mo, August 29, after an illness of six months

George S Balsbaugh, M.D Jefferson Medical College, Philadelphia, 1861, died at his home in Forreston, Ill, August 26, after a long illness, aged 75

J F Shackleford, M.D Medical College of Georgia, Augusta, 1850, died at his home in Trenton, Tenn, September 1, from chronic bronchitis, aged 77

James D Kratzer, M.D College of Physicians and Surgeons Keokuk, Iowa, 1886, died at his home in Lancaster, Mo, August 16, aged 49

George T De Verter, M D Miami Medical College, Cincinnati, 1872, died from paralysis at his home in Waterman, Ind, August 11, aged 65

Lewis Melton, M D College of Physicians and Surgeons Keokuk, Iowa, 1876, died at his home in Wheatland, Cal August 8, aged 68

Tilghman Seems, M D College of Physicians and Surgeons, Keokuk, Iowa, 1872, of Mitchellville, Iowa, died in Jamesboro Ont, August 11

John D Karr, M.D College of Physicians and Surgeons, Keokuk, Iowa, 1892, died at his home in Alva, Okla, August 9, from apoplexy

Josiah H Helmer, M.D Albany (N Y) Medical College, 1847 of Lockport N Y, died suddenly at Theresa, N Y, August 19 aged 83

George W Thompson, M.D Ohio, 1878, died at his home in Union City, Ind, August 13, after an illness of five years, aged 73

George R. Harris, M.D Atlanta (Ga) College of Physicians and Surgeons, 1901, died at his home in Rayne, La, July 30, aged 28

James C Smith, M D Vanderbilt University Nashville, Tenn, 1885, of Birmingham Ala died in Memphis, Tenn, August 23, aged 37

Walter P Ellis, M D University of Louisville, 1881, died at his home in Livermore, Ky, August 13, from paralysis, aged 49

John H. Lueke, M D University of Munich, Germany, 1867 of Cleveland, Ohio, died recently in Bremen, Germany, aged 65

W B J Hardman, M.D Jefferson Medical College, Philadelphia, died at his home in Commerce, Ga, August 21, aged 82

John Walker Gill, M D New York, 1887, died at his home in Flushing, N Y August 22, from Bright's disease, aged 61

J J Hunt, M.D Royal College of Physicians, Dublin, Ireland 1868, died at the county farm, Burlington, Iowa, August 30, aged 56

James Dodd, M.D Medical College of Ohio, Cincinnati, 1859, died at his home in Bloomington, Ind, August 21, aged 72

T Charles Bower, M.D Pennsylvania, died at his home in Superior, Mont, from pneumonia, July 6, aged about 45

Albert B Harris, M D Jefferson Medical College, Philadelphia 1888, died at his home in Wilmington, Del, August 18

William S Fraleigh, M D McGill University, Montreal, 1869, died at his home in Toronto, Ont, August 19, aged 58

William E Parker, M.D University of Vermont, Burlington 1883, died suddenly at his home in Boston, August 16

William Davis, M D, died at his home in Ripley, W Va August 18, from disease of the bladder, aged 78

Josiah S Devore, M D Ohio, 1882 died at Dunsmuir Cal August 4, after an illness of one month

Esther Woodman Taylor, M.D Illinois, 1872, of Boston died recently at Wells, Maine, aged about 70

Joseph A Crabtree, M D Ohio, 1875, died at his home in Akersville, Ky, July 28, aged 61

Sim Hopkins, M D, 1852, died at his home in Leona Texas, August 25, aged 76

T N Horner, M D, died at his home in Whitesburg Tenn July 18, aged 84

Deaths Abroad.

Karl Weigert, M D, professor of pathologic anatomy since 1884, and director of the Pathologic Institute at Frankfurt a M, died there from a stroke of apoplexy, August 5, aged 59 He is known the world around for his pioneer research in bacteriology and pathologic anatomy His research on the anatomy of smallpox and on the relations between the anilin dyes and the animal tissues laid the foundations, thirty years ago, for much of our present knowledge of pathologic anatomy and bacteriology His neuroglia staining is considered his greatest triumph, opening the way for study of the structure of the brain from new standpoints Among his other fruitful works are those on tuberculosis of the veins, staining of bacteria, proliferation of cells under external stimuli, 'coagulation necrosis,' encapsulation of tuberculous foci, etc He has trained a number of pupils who do him honor, among them Prof Paul Ehrlich Weigert died without having been distinguished by the authorities in any way commensurate to his services to science

Anton Drasche, M D, professor of epidemiology at Vienna, member of the Austrian sanitary council, and privy councilor, died at Vienna, August 28, aged 78 He was celebrated for his investigations on cholera and other epidemic diseases and their prophylaxis, and was one of the founders and editors of the *Bibl der gesamt med Wiss*

Erich Bennecke, M.D, professor of surgery and director of the surgical policlinic at Berlin, died there, August 1, aged 39 He succumbed to septic infection from a scratch during an operation His death followed close on the retirement of the chief of the policlinic, Professor König

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns The writer's name must be attached, but it will be published or omitted as he may prefer It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer]

Cerebrospinal Meningitis

Koplik, in the *Med News*, June 4, 1904, concluded that the disease, very like pneumonia, is a self limited one, and all we can do is to relieve the sufferings of the patient and treat the complications

GENERAL TREATMENT

Fischer, in the *Med Record*, gives the following general outline of treatment of this condition

Dietetic—To sustain life the child must be fed When there is gastric irritability peptonized milk or peptonized yolk of an egg should be given per rectum Gavage may be resorted to and light nutritious foods, such as whey, white of egg, soups and broths should be given at regular three or four hour intervals

Fever —The temperature of the room should be kept at from 65 to 70 F If the fever is high, shave the head and apply an ice bag to the head and at the nape of the neck A mustard footbath will relieve the cerebral symptoms in some cases Tub baths of tepid water may be tried or the cold pack or ice coil

Medication —For the restlessness the author recommends the hypodermic administration of morphin sulphate, gr 1/30 (2 mg) repeated three times a day or oftener if required In some cases five or ten drops of the spirits of chloroform given with the food every three to four hours is beneficial A ten grain dose of the bromid of sodium may be given every three to four hours until the cerebral symptoms are modified Hyoscyamin tablets of 1/100 of a grain are useful when active delirium is present Suppositories containing the following may be given

℞ Chloralamid gr x | 65
Ext belladonnæ gr ⅛ | 008

M Ft suppos No i Sig Use to promote quiet or sleep

If stimulants are required he recommends the tincture of musk or the hypodermic injections of camphorated oil, or black coffee Of other medication he says The inunction of silver ointment along the spine at least fifteen minutes at a time, can be tried and repeated several times a day Large doses of iodid of potassium or sodium iodid 15 to 60 gr (1 to 4 gms) or even more daily may be tried Mercurial ointment rubbed into the scalp and nape of the neck was used in one case that recovered

LUMBAR PUNCTURE

Koplik, in the article quoted from above, discusses this subject and his observations from his own experience justify the following conclusions

1 It is not curative and can not prevent relapses

2 The temperature is not a guide as to the efficacy of the procedure of lumbar puncture

3 It certainly relieves symptoms of pressure, therefore, if the irritability is great and headache is severe, as may be judged, even in children by the rational symptoms, lumbar puncture is indicated

4 It is also indicated if rigors are present, the withdrawal of the purulent fluid will give the same relief as when withdrawn from any other cavity

5 In cases of rigidity, even opisthotonos (basal meningitis) the lumbar puncture often fails

6 The procedures of injecting chemicals or antiseptic fluids have not lessened the mortality

7 It aids in the prognosis, if the fluid is thick and purulent, and flows slowly from the canula, the prognosis is grave. Encouraging are the cases in which the fluid is cloudy or shows a straw color

8 It is probable that the lumbar puncture aids materially in preventing certain complications, such as hydrocephalus, which is a very serious consequence

Method—The method used is that advocated by Quincke The author has never had an accident of any consequence If he is unsuccessful and obtains what is known as the dry tap, he repeats the puncture in another place, but has not gone further than this In cases in which hemorrhage occurred no ill effects followed Quincke believes that the hemorrhage is due to the puncture of a vein in the subdural space

Number of Punctures—There is no set rule If the temperature remains low, and the irritability and headache are not marked, it is well to wait If there is a subsequent rise of temperature another puncture may be made, but not oftener than at an interval of four or five days

Quantity of Fluid Withdrawn—This varies, in some cases the fluid flows very rapidly from the canula, is clear or very slightly turbid, and in a short space of time 60 to 70 cubic centimeters are withdrawn before there is a relief of tension which is judged chiefly by the rapidity with which the fluid flows from the canula If the fluid drops slowly he rarely draws more than 30 c c

Summer Diarrheas of Children

Lowenburg, in the *Therapeutic Gazette*, gives the following general outline of treatment for all forms of diarrheas

PROPHYLAXIS

Remove or mitigate the etiologic factors Of these the summer heat and improper feeding are the most important Heat favors fermentative changes in milk, which in turn is an active cause in the production of intestinal disturbances in children The child of the rich can be placed in proper hygienic surroundings either in the city or taken to the country or sea shore The children of the slums require our attention and services most These children should be kept constantly in the open air, preferably in the parks, should sleep in cool, well ventilated apartments, and the beds should be covered with mosquito netting Cool bathing should be indulged in regularly Care must be taken regarding the dress Do not overclothe the child Soft, unstarched materials should be used and the dress loosely and lightly adjusted, light woolen garments being worn next to the skin only The author discusses at length the importance of the care and preparation of the food, believing with all authorities that proper feeding requires the best attention First in importance, the physician should insist on maternal nursing If this is impossible, a healthy wet nurse should be obtained Weaning should take place in the fall or winter if possible Absolute cleanliness should obtain in the care of the nursing bottle, nipples and all utensils with which the milk comes in contact before being taken by the infant The nipples should be turned inside out and scrubbed, then washed in sterile water, and kept in a boric solution until ready for use The bottles should be cleansed and boiled The milk should be secured from a reliable dairy, the sanitary condition of which is known to be good. The author believes that the milk should be sterilized and afterward kept on ice until used (In this particular other authorities disagree and believe that the best plan to pursue is to obtain a milk which is known to be procured under the most cleanly conditions, so that the milk shall not become contaminated from the time it is taken from the udder of the cow until it is consumed by the infant The method of producing milk under the most recent hygienic conditions has been so perfected by some dairies that the obtaining of pure milk has become practicable The author further deprecates the use of any so called milk preservative

The milk should be modified after some one of the methods given, remembering that each case is a law unto itself and the milk must be so adjusted to meet the nutritional needs of the child and its state of health and not be governed entirely by its age

DIETETICS

The beginning of an attack of summer complaint is to be met by the withdrawal of all food, be the child breast or bottle fed. The patient is to be starved for from twenty-four to forty-eight hours. This is one of the best means of controlling vomiting and of preventing further fermentative changes in the bowel. Small quantities of sterile water may be allowed at short, fixed periods. After the starvation period, small amounts of cereal water may be allowed, as barley or rice water. Albumin water, if it agrees, is very useful, and when beef juice is added it will furnish nourishment for many days. It is also a good vehicle for the administration of brandy when a stimulant is indicated.

After the vomiting has ceased and the intestinal canal has been cleansed a gradual return to milk is made, and this must be done with the greatest caution. Better go too slow than too fast. Begin with a very weak milk mixture with the proteids, ½ per cent., peptonize and feed in small quantities and at short intervals. Very gradually increasing the quantity, lengthening the interval and omitting the peptonization, and as the digestive organs become stronger the per cent. of the proteids may be increased until the milk equals the strength of the mother's milk.

Many times it is advisable to omit the casein from the cow's milk because of the difficulty of its digestion in the human stomach, and feed the infant with whey instead, which contains the soluble albuminous portions of bovine milk—lactalbumin and lactoglobulin. The author also recommends the use of dextrinized gruel added to the milk when the whey is not used. This substance so changes the casein of the cow's milk as to make it coagulate in finer curds.

METHOD OF PREPARATION OF DEXTRINIZED GRUEL

The following is the method as advocated by Chapin: One tablespoonful of wheat flour plus one pint and a half of water, boiling the mixture for fifteen minutes. This is followed, after cooling, by the addition of a dram of a solution of diastase, which renders the gruel thin. Water should be administered in small amounts throughout the course of the disease, to allay thirst, reduce fever, diminish toxemia, and supply the tissues with fluid.

MECHANICAL TREATMENT

Lavage has but one indication in cases of summer diarrhea, viz., uncontrollable vomiting. One washing is usually sufficient. Colonic flushing is indicated in the following conditions: Where there is evidence that undigested food or putrescible material exists in the intestinal canal, a copious colonic irrigation of normal salt solution, combined with a calomel purge and correction of the diet will give quick relief. In ulcerative colitis, when the stools are mixed with blood, an irrigation with a 1 to 8,000 silver nitrate solution serves a useful purpose. High fever is best controlled by cold irrigations of the colon. Colonic flushing will relieve and prevent intestinal putrefaction, allay thirst, cleanse the bowel and prepare it for the absorption of medicines and nutrient enemas. Hypodermoclysis is especially useful in cases of cholera infantum during the stage of collapse following excessive purgation. Its greatest sphere is in those apparently hopeless cases made so by urinary suppression and threatened cardiac and respiratory failure.

MEDICINAL TREATMENT

In cases of acute intestinal indigestion and the fermentative type of diarrhea the symptoms are speedily controlled by emptying the intestinal canal by the use of castor oil in dram doses if there is no vomiting; it removes the offending material and has a secondary constipating effect. In diarrhea, associated with vomiting, the author recommends the following:

R.	Hydrarg. chlor. mitis	gr. i		06
	Sodii phosphatis	gr. xxx	2	
	Pulv. ipecac.	gr. ss		03
	Sacchari lactis	gr. xx	1	30

M. Ft. chart. No. x. Sig.: One every half hour.

The so-called intestinal antiseptics are inefficient because of the necessarily small doses. Salol may be given in from 3 to 5 grain doses, zinc sulphocarbolate in doses of from 1/6 to 1/2 grain.

It is useful to administer dilute hydrochloric acid in doses of from 5 to 10 minims in cases associated with high fever.

Of the astringents morphin is best given hypodermically, gr. 1/800, combined with atropin, gr. 1/300, to a child under 2 years of age; morphin must be given cautiously, and only when the intestinal canal is clean.

Bismuth, in the form of the salicylate or the subgallate should be given in large doses, gr. v to xv. The salicylate is best given in the fermental type and the subgallate and subnitrate in the inflammatory forms associated with blood, mucus and tenesmus.

Fever is controlled by hydrotherapy. Indications for stimulation are met by the use of brandy, strychnin and digitalis, and must be used in full doses. Atropin in doses of 1/250 grain has a remarkable effect in cases associated with watery stools, pinched features, a high internal temperature and a cold, clammy surface.

Of the serum treatment it must be said that up to date it is disappointing and too much in the experimental stage to be of practical benefit.

Medicolegal.

Peculiarities and Requirements of Dying Declarations.—The Supreme Court of Kansas says, in State vs. Knoll, that a dying declaration is hearsay evidence, and is taken out of the rule excluding such evidence, because of reasons of necessity, and because it is supposed that a realization on the part of the declarant of the certain and speedy approach of death affords as powerful incentive to tell the truth as does the administration of an oath. In order to render such declarations admissible, it must be first shown that the declarant was not only in articulo mortis (at the point of death), but under the sense of impending death, without hope of recovery, at the time such declarations were made. But the statements made in this case by the declarant that he had to die of the whipping he had received from the defendant, and that any hour, any day, he might die, the court does not consider sufficiently showed his sense of impending death to render his statements competent as dying declarations. At the same time it says that it is quite true that, where the sense of impending death, without expectation or hope of recovery, exists at the time of making of the statement, such statement is not rendered inadmissible by a subsequently entertained belief or hope on the part of the deceased that he may recover.

Liability for Criminal Act of Person with Delusions.—The Supreme Court of Alabama says, in the homicide case of Porter vs. State, that the mind may, in a sense, be said to be unsound where its possessor is suffering from delusions, hallucinations, and illusions, and yet he may be held responsible for a criminal act, where the intent is an essential ingredient of the offense, if these things are not the products of a diseased brain. In this case, it was open for the jury to find, under the evidence, that the species of insanity or mental unsoundness, if it existed at all, with which the defendant (Porter) was afflicted, was a temporary aberration which sometimes accompanies or follows intoxication, and is often accompanied by delusions, hallucinations, and illusions. This is not such insanity as confers legal irresponsibility. Insanity, to relieve from criminal responsibility, must be caused by or result from disease or lesion of the brain. Furthermore, if the defendant was afflicted with a disease of the brain which rendered him insane, he may have known it was wrong to take the life of the deceased, and, under the evidence, it was open to the jury to so find. If he had this knowledge, in order to relieve him of criminal responsibility, two conditions must concur: (1) If by reason of the duress of such mental disease, he had so far lost the power to choose between the right and wrong, and to avoid doing the act in question, as that his free agency was at the time destroyed, (2) and if, at the same time, the alleged crime was so connected with such mental disease, in the relation of cause and effect, as to have been the product of it solely

Liability for Giving Illegal Prescription for Liquor.—The Court of Criminal Appeals of Texas takes a somewhat new stand on this subject in the appeal of Williams vs. State. It says that the facts showed that the physician gave an illegal prescription, on which the sale charged was made. He was not interested in the saloon, and did nothing more in furtherance of the sale than the mere giving of the prescription which procured it. The state's insistence was that he was guilty of a sale by virtue of having given an illegal prescription. Under some expressions in Stephens' Case (Tex. Cr. App.) 73 S. W. Rep. 1056, and McLain's Case, 43 Tex. Cr. R. 213, 64 S. W. 865, this was a proper way of prosecuting him. But the real point in the Stephens Case was that there must be a sale, before the physician would be guilty for giving the illegal prescription. However, on a more mature consideration of the Stephens and McLain cases, and in view of the variant views on the question of indictment, the court has reviewed the authorities, and now holds that the indictment in this case, charging the physician in the usual form, with selling intoxicating liquors in Smith County after such sale had been prohibited in said county, was defective, when applied to the facts intended to be covered by this prosecution. Then in order to eliminate any doubt as to what is a good indictment, under the laws of Texas, against a physician for giving an illegal prescription, the court lays down what it holds to be a proper form. Continuing, it says that whenever a party is particeps criminis or aids and abets the sale, he is guilty if his acts bring him within the statutes of principals, as applicable to misdemeanors, whether he be a physician or other person. But in order to convict a physician for giving an illegal prescription on which a sale is made, such sale must have been accomplished by the physician giving the patient a prescription when he well knew at the time he gave the prescription to the applicant that he was not actually sick, or if the proof showed that the physician had not made a personal examination of the applicant for the prescription, this would authorize a conviction provided a sale was obtained in either instance under said prescription. Wherein these views conflict with the McLain and Stephens cases they are overruled. The court understands that this last proposition is also at variance with its views expressed in Stovall vs. State (Tex. Cr. App.) 39 S. W. 934, McQuerry vs. State, 40 Tex. Cr. R. 571, 51 S. W. 247. It therefore held that in order to make a valid prosecution the state must prove that the physician not only knew that the applicant was not actually sick, but that the state must prove he gave the prescription without a personal examination. It now holds that if the state proves either—that is, that the physician knew the applicant was not sick, or if he gave a prescription, whether he knew the applicant was sick or not, without a personal examination, and the sale was obtained on said prescription—in either event he would be guilty of a violation of the law. If the proof in this case had shown, as in the McLain Case, that the physician was aiding and abetting in the sale of the whisky, in addition to the giving of the prescription, in such manner as would make him a principal, he would be guilty. As before stated, this would be true whether he was a physician or not. But the mere fact of giving an illegal prescription on which the sale is procured would not authorize the prosecution of the physician giving the same for the sale thereby procured under an ordinary indictment for selling.

2. **Injection Treatment of Internal Hemorrhoids.**—Martin discusses this question in all its phases and describes his method as follows: The rectal speculum devised by the elder Martin is inserted to its full extent; remove the obturator and by gentle rotary and downward motion examine the mucosa carefully. When the edge of the speculum is withdrawn as far as the upper margin of the internal sphincter, any hemorrhoids present on the side examined will prolapse into the mouth of the aperture. Selecting the largest one for treatment, the patient by coughing renders this more prominent. Carefully swab off the surface with some mild antiseptic solution (such as creolin 1 per cent.) and make the injection directly into the most prominent portion of the pile. Withdraw the speculum before removing the needle, allowing the rectal walls to collapse and preventing the escape of fluid or any bleeding. Ordinarily he inserts a suppository containing 32 milligrams (½ gr.) of cocain to prevent the slight discomfort which may be felt for an hour or so, and also a suppository containing 18 c.c. (3 m.) of ichthyol. The ichthyol suppositories are used during the entire course of the treatment, one to be inserted after each bowel movement and one at bedtime. The syringe employed is an ordinary all-metal hypodermic fitted with a four-inch metal extension. The needles are No. 27 gauge and three-quarters of an inch long. The solution used is composed of equal parts of phenol, Boroccit and distilled water, freshly prepared and filtered. Should the fluid become opaque it must be discarded. Ordinary cases require an injection of from 42 c.c. to 92 c.c. (7 m. to 15 m.). The injections should be made at intervals of from five days to a week, and only one pile should be treated at a visit. Under no circumstances does Martin inject external hemorrhoids, nor any structures covered by true skin. Internal hemorrhoids and cases in which there is a prolapse of the mucous membrane only are treated by this method. When an internal hemorrhoid, from long-continued irritation and inflammation, has become excessively hypertrophied and fibrous, the wisest course to pursue is to anesthetize the tumor and remove it surgically. The injections should be continued until all the hemorrhoids have been absorbed and the rectal mucosa does not prolapse into the speculum to any extent when the patient coughs hard. If any hemorrhoidal tissue remains, the percentage of recurrences will be materially increased. If the recurrence does take place and the primary divulsion has been performed thoroughly, a second divulsion rarely is necessary and the patient usually can be relieved permanently by a few additional injections.

4. **Retrodeviations of the Uterus.**—Mellish summarizes his paper as follows: Retroversion is common in virgins but rarely is congenital. Improper clothing during the period of puberty, together with lack of exercise and development, act as causative factors in fully as many cases of retrodisplacement as subinvolution after parturition. Retrodeviations are present in at least 15 per cent. of all gynecologic patients, and in the majority of cases are a source of discomfort or disease. In a large percentage of the cases the intelligent use of the pessary will effect a cure, but when used unintelligently it is positively dangerous. In many cases surgical treatment is absolutely essential. No method of shortening the round ligaments within the abdomen will effect a cure in all cases, because these methods fail to eliminate the weakest part of the ligament, the portion within the inguinal canal. The Alexander-Adams operation is right in principle and will, more or less modified, maintain its position as a classic operation for the cure of retrodisplacements. The Gilliam modification is easy of execution and meets all the indications for the successful treatment of the displacement and of intra-abdominal complications which may be present. Ventral suspension and ventral fixation are "unphysiologic" operations. They should not be performed on patients susceptible of child-bearing. Vaginal operations in fruitful women are mentioned only to be condemned.

11 *Pyloric Stenosis in Infants. J. G. William Greeff.
12 *The Modern View as to the Etiology and Treatment of Eczema. Zama Feldstein.

8.—See abstract in THE JOURNAL of July 2, p. 70.

9. **Concerning Shock.**—Vale has made a careful study of that peculiar symptom complex known as shock, and concludes that shock is not due to the exhaustion of any one nerve center or paralysis of any one system, but that the function of every organ, tissue and cell in the body is depressed as the result of a powerful impression on the nervous system which dominates all the functions of life. Experiments performed suggest that an outpouring of lymph into the tissues in excess of normal, and consequent inspissation of the blood, is one factor which added to the lowered vasomotor tone occurring in shock aids in the lessening of blood pressure so characteristic of that condition. This loss of fluid by the blood in shock, a state of vital depression but little short of death itself, conforms to the fact long well known that after death fluid passes into the tissues from the blood vessels. This loss of fluid by the blood and corresponding gain by the tissues as death occurred was sought for and noted in rabbits—as demonstrated by a gain in the specific gravity of the blood and loss in specific gravity of the tissues. The enfeebled action of the heart is largely secondary to the lowered blood pressure; the temporary rise in blood pressure produced by an intravenous injection of salt solution restores the force of heart contractions. The wan, pinched features are due to the empty peripheral vessels and feeble circulation, undoubtedly, however, most marked where there has been an excessive fluid loss by both the blood and tissues, as in peritoneal injuries. The lessened secretions are due to the lowered blood pressure. The feeble circulation and lessened activity of all the organs and general arrest of metabolic processes explain the fall in body temperature. The shallow, slow respiration is in accord with the phenomenon of aerated venous blood. Impaired consciousness is due to the overwhelming nature of the impression on the nerve centers, the feeble circulation augmenting and prolonging this effect.

11. **Pyloric Stenosis in Infants.**—Greeff reports a case of this kind in which he made the diagnosis *intra vitam*. The child was born after a normal labor. For the first two weeks it did quite well, though the stools were not always satisfactory. The child was bottle-fed from the fourth day on, getting two ounces every two hours, day and night, one part milk and two parts water. When two weeks old it started vomiting, became very restless, had temperature and bad smelling stools. When twenty-three days old it was crying constantly, looked very puny, with the skin in loose folds. Stools and urine scanty. The spleen, lungs and heart were normal; liver slightly enlarged; stomach very much enlarged and distended. The lower curvature could be made out three finger breadths below the umbilicus. The milk was stopped and thin gruels, barley water first and later of oatmeal, were substituted. Lavage and colonic flushings were given every day. Stomach washings showed no bile, odor very sour, no free hydrochloric acid. Bowel irrigation showed mucous casts and some thick matter. When the child was one month old a wet nurse was engaged; the child nursed eagerly, but vomiting persisted just the same, coming in great gushes either immediately after each feeding or after every two or three feedings. The child seemed hungry and would take the breast again immediately after vomiting and then usually keep the food down. This also immediately after the stomach washings. The child lost steadily in weight, although at times it appeared to gain a little. The diagnosis of pyloric stenosis was made and a posterior gastroenterostomy was done. The child died from shock twelve hours after the operation. The autopsy confirmed the diagnosis.

12. **Etiology and Treatment of Eczema.**—Feldstein holds that eczema is a parasitic disease and the only thing necessary to produce an eczema is the congestion of the skin, which may be caused by constitutional ailment or defect, or by outside influences such as cold or chill. The parasite, having once been called into activity, as it were, the primary cause can be cured, but the effect—the parasite—remains until destroyed by a parasiticide sufficiently penetrating to establish contact and sufficiently stimulating to restore the skin to its natural activity. Constitutional treatment is only useful as an adjunct to the local treatment. An effective parasiticide is absolutely necessary. He has been using a mixture of Juniperus oxycedrus, stavesacre, Pinus silvestris and Eugenia caryophyllata, prepared without any animal fat. This is a parasiticide capable of deep penetration and at the same time harmless to the tissues. It is necessary to commence with weak applications so as to avoid overstimulation. The parts most liable to overstimulation are the genitals and the scalp. As a general rule, the less drugging the better. If internal remedies have to be employed they should be given for a definite purpose and in accordance with definite indications.

19 Remarks on the Use of the Nasal Saw. George A. Richards.
20 Case of Poisoning by Illuminating Gas. Samuel J. Lupp.
21 Status Lymphaticus and Death Following Chloroform Anesthesia. J. A. Simmons.

14. **Arthritis Deformans of the Spine.**—Lerch describes the case of a man aged 54, who six years ago noticed a slight stiffness in the neck following a trauma, which slowly progressed downward, finally involving the whole spine, making it stiff and immovable, bending him and forcing him to stoop over considerably. All other joints are free, with the exception of the shoulder joints, which are very slightly involved. The patient denied having had syphilis and shows no traces of lues. There is no inherited tendency to the disease and the cause seems to be due to a concussion of the spine produced by a fall from a wagon, the patient landing on his hands, face and chest. The first symptoms appeared four months after the fall.

15. **Infectious Nature of Malignant New Growths.**—Richardson reviews the literature with reference to this subject and concludes that the various mentioned so-called parasites failed to make good in fulfilling the requirements of an infecting agent. The vast majority of competent pathologists are of the belief that the so-called parasites are changed or degenerated cells not yet thoroughly classified. Contaminations could not be excluded in the cases that showed any growth out of the vast number of cultures taken on every known media. The tumors produced by *inoculation of blastomycetes* show them to be only granulomata. Blastomycetes can be cultivated from the air, hence contamination is always possible. In fact, no one has yet been able to grow or demonstrate parasites in *malignant growths*. The facts and arguments are so overwhelmingly on the side of the embryonic cell theory that for the time being at least we shall have to believe that the latency is due to an abnormal play of forces within the body of which as yet we know but little. A benign tumor is an abnormal deposit or growth of normal tissue, at least for a time; a supernumerary toe is normal tissue growing in an abnormal position. The author believes that time will show a reaction in the present movement of parasitism and many of its strongest advocates will refute their theories and admit that their conclusions were reached without sufficient investigation.

16. **Roentgen Rays in Joint Tuberculosis.**—The author emphasizes the efficiency of the Roentgen ray in the treatment of joint tuberculosis. Two cases are cited and others are referred to that were benefited by the Roentgen ray after all other treatment had proven futile. Not only were the patients very soon relieved, but they feel well and are strong and hearty, some with ankylosis, others without, according to the

individual circumstances of each case The proper support adapted to each individual chronic case must be supplied so that the joint will become ankylosed in about four months under the influence of the radiation, and in simple tuberculous synovitis of any joint a prompt cure is obtained, with perfect motion and usefulness of the joint, by injecting it once with iodoform emulsion, formalin and glycerin and exposing it immediately to *x* ray treatment It is well to observe by means of fluoroscopic examination from time to time, the results of the *x* ray treatment, and to be constantly on the watch for any special susceptibility of the patient, autointoxication, the regulation of the bowels with all the rules of proper hygiene, good nutrition, light and fresh air

17 **Bacteriuria** —According to Keyes, bacteriuria is not a simple urinary infection without parietal lesions It is but a symptom of catarrh in certain parts of the urinary tract, in fact, it is the chief and only striking feature of certain diseases, notably certain varieties of catarrhal pyelitis, such as typhoid, puerperal and acid retention pyelitis, any one of which may become suppurative Cystitis never causes bacteriuria, and prostatitis and spermatocystitis only exceptionally cause bacteriuria

32 Valuable Suggestions from the Inspection of Urine I S Wile
33 Quantitative Albumin Determination K M Vogel

28 **Osteoplastic Amputations** —The burden of this paper is to prove the superior advantages of amputation stumps formed by osteoplastic methods over those formed by the older methods A stump is perfect when it is fully able to carry on support and locomotion The essential factor of a good stump is that in no case must the bone expose on its distal extremity a wounded surface, and in order to obtain this result it is necessary to cover or seal the wounded surface with bone covered by its periosteum or, if this be impossible, it is preferable to exarticulate It is for this reason that Bier devised osteoplastic amputation, the underlying principle of which is to form either from the bone amputated or from a neighboring bone, a thin osteoperiosteal flap, which obtains its mobility from a hinge of periosteum This osteoperiosteal flap is brought into correct apposition with the sawn surface of the amputated bone, and its periosteum is sutured to the opposed periosteum and other convenient structures This operation is indicated in every amputation, except in those cases in which the general condition of the patient demands a hasty termination of the operation, and in cases where the nutrition of the parts is so poor that there is danger of necrosis of the osteoplastic flap

29 **Chronic Suppurative Otitis Media** —McCaw says that the importance of this condition and the early application of appropriate treatment should be appreciated more fully by every physician He believes that many patients die from intracranial complications in which the chronic suppurative middle ear disease is never recognized as a causal factor Chronic otorrhea is not given the importance that its gravity demands The treatment should be based on the pathologic condition present in each case In addition to proper attention to the nose and nasopharynx, appropriate treatment to the middle ear will yield good results in a large percentage of cases Where caries is limited to the ossicular chain and there are no contraindications, ossiculectomy should be the operation of selection Cases presenting symptoms of extension beyond the tympanic cavity should be subjected to the radical operation

31 **Aseptic Catheterization** —The authors consider the sterilization of catheters, the preparation of the urinary canal and the introduction of the instruments in an aseptic manner They detail a large series of experiments with infected catheters and summarize those methods of sterilization which prove to be safe and simple, as follows 1 Soft rubber catheters are rendered sterile by being boiled five minutes, preferably in sodium chlorid solution, care being taken that the solution fills the lumen of the catheter As a matter of precaution the catheter should be washed with soap spirits and running water after use 2 Hard rubber and silk and cotton woven catheters should be boiled five minutes in a saturated solution of sulphate of ammonia Each instrument should be wrapped separately in gauze or a towel, or, if several catheters are to be sterilized, in such a manner that their surfaces shall not come in contact with the sides of the vessel or other catheters 3 Ureter catheters can be folded and wrapped in a towel so that their surfaces are kept apart and boiled for five minutes in a saturated solution of ammonium sulphate 4 Cystoscopes should be sterilized by first washing them in soap spirits and water then vigorously rubbing them for two minutes with two different pieces of gauze or cotton wet with soap spirits, and then with alcohol, for one minute The channel of the catheter can be cleansed by means of a brush first brushing with soap spirits and then with alcohol Instruments can be kept aseptic if they are snugly wrapped in a piece of gauze or towel wet with soap spirits

43 Treatment of Post operative Peritonitis Egbert H Grandin
44 Treatment of Gonorrheal Peritonitis in Females—Young and Older A Ernest Gallant

37 **Relation of Appendix to Pelvic Disease** —Peterson removes the appendix in every case where the abdomen is opened for other purposes unless the patient's chances of recovery are jeopardized by the addition of five minutes' time required for the removal Two hundred appendices thus removed were subjected to careful microscopic examination Thirty two and five-tenths per cent were absolutely negative, 28 5 per cent showed evidences of active catarrhal inflammation or ulceration of the mucosa, with atrophy of the mucosa and lymphadenoid tissue or muscularis, associated with fibro

blastic proliferation or formation of scar tissue, 20 5 per cent were of doubtful significance, showing hyperplasia of the lymphadenoid and connective tissue, dilatation or constriction of the lumen, local or general atrophy of the muscular coat, unattended by conclusive evidences of inflammation, 14 per cent showed every evidence of a former inflammation, 3 per cent were acutely inflamed, 1 5 per cent showed evidences of periappendiceal inflammation Thus, 53 per cent showed practically no evidence of disease, while the remaining 47 per cent were diseased As the result of his clinical observations Peterson concludes that The average length of the appendix is between 8 and 9 cm, the maximum length being found between the ages of 20 and 30 After this period the average length of the appendix is less, probably because of normal atrophy or because of inflammatory changes Menstrual pain may be due or enhanced by the presence of an inflamed appendix. The congestion incident to menstruation increases the inflammation and gives rise to attacks of appendiceal colic It is exceedingly difficult to differentiate between pain due to pelvic lesions and pain due to chronic appendicitis The shape of the appendix and the existence of adhesions can not serve as an index of its normality or disease The appendix is the seat of fecal concretions in at least 8 per cent of all cases but this does not signify disease Nearly 50 per cent of patients with chronic disease of the appendages show accompanying disease of the appendix This may be due to direct contact of these structures, or the infection may travel from one to the other through the lymphatics In 50 per cent of patients with uterine fibromata there is accompanying disease of the appendix In 70 9 per cent of patients with ovarian cystomata the appendix is diseased The appendix is not infrequently adherent to an ovarian cyst and may even infect the latter Since it is impossible for the surgeon to determine by gross appearances which appendix is diseased, and since nearly 50 per cent of appendices where the abdomen is opened for other purposes are found diseased, it is the surgeon's duty, in the absence of contraindications, to remove the appendix in every such case. Systematic examination of a series of removed appendices shows the occasional presence of primary carcinoma in such an early stage that it could not have been detected by inspection at the time of operation Even were carcinoma of the appendix not commoner than once out of 200 abdominal sections it would still be an argument in favor of the removal of the appendix in every case where the abdomen is opened for other purposes

38 **Clamp and Cautery in Appendectomy**—Eastman criticises the usual methods employed for abscission of the appendix and disposition of the stump because in many cases they fail to effect a complete cure and often are responsible for the formation of fecal fistulæ and sepsis He believes that a light clamp with broad accurately fitting protecting shields, applied to the base of the appendix, will effectually preclude the possibility of pus from the cecal wall or appendix contaminating the neighboring serosa or floating into the peritoneal cavity Very little pus or other fluid contents will escape, though the appendix be quite full, if the separation is made with the hot cautery knife between two clamps and moreover whatever fluid may escape will have been rendered sterile by the heat of the cautery though this heat need not be intense enough to burn or sear the serosa If the heat is feared the appendix may be cut off with scissors or knife, while the special clamp with its trough like shields protects the peritoneal cavity from contamination The author's method is a modification of the one practiced by his father, the late Dr Joseph Eastman It consists in the addition of the removable shields in which the escaping contents of the appendix are caught, and the changing of the grooves in the jaws so that they run not transversely but parallel to the jaws of the forceps The forceps are applied close to the cecum the jaws parallel to the ventral longitudinal muscle band Light artery forceps are applied above the clamp and the appendix is severed between the artery forceps and clamp with a Paquelin cautery The removable shields catch all escaping fluid from the appendix The slightest traction releases them After they have been displaced the base of the appendix is held in a single light clamp Either pursestring sutures or Lembert sutures can then be introduced After removal of the forceps the canal is explored and the stump invaginated The use of the forceps minimizes hemorrhage and in most cases will shorten the time of operation The cautery used is a light cau'ery blade and the heat is just sufficient to separate the appendix and destroy bacteria No difficulty is experienced in making this operation through the small gridiron incision The forceps should have slender jaws beveled on the under side to avoid cutting the serosa of the cecum where they compress

39 **Ovarian Pregnancy**—Webster gives the history of a case of ovarian pregnancy which necessitated the removal of the ovary during the third month of the pregnancy The macroscopic and microscopic appearances of the specimen are described in detail and numerous illustrations are shown

45 Errors in Diagnosis of Ureteral Calculus Byron Robinson
46 *Conservative Surgery J W Cokenower
47 A New Method in the Management of Irreparably Crushed Extremities Charles H Wallace

46 **Conservative Surgery**—The subject of ovarian neurosis says Cokenower, is one of the most difficult, because of the impossibility to fix a standard from which to determine the beginning of surgical treatment, hence, the question is one of diagnosis rather than of surgery, and the thing to do is to decide whether the symp'oms arise directly or indirectly from pelvic disease All diseases are not the result of pelvic disease The intimate relationship existing between diseased conditions of the reproductive organs of the female and functional disturbance and organic change in other parts of the body should be better understood, also that fermentation and putrefaction within the intestinal canal will produce autoinfection and intoxication, ptomaines and leucomaines, which are the most common cause of nervous disease Many surgical procedures have failed utterly to relieve the condition for which they were advised Many operations which a few years ago were very popular for the relief of supposed ovarian nervous troubles have grown in disfavor and are now seldom done Operations on the ovaries that preserve the menstrual and reproductive function should be employed, when possible, in lieu of complete extirpation Healthy displaced ovaries may be anchored to the posterior surface of the broad ligament, or by shortening the infundibulo pelvic ligament Sterile women and married women who are using means to avoid pregnancy are unfavorable subjects on whom to do conservative operations on the ovaries Conservative operations should be avoided as a general rule, in all pus cases

48 **Dislocation of Lachrymal Gland**—Jackson reports a case of dislocation of the lachrymal gland in a man aged 44, who had been thrown from a wagon, falling on his head, which struck a sharp stone He received a wound in the upper lid parallel to the orbital margin and about one inch long, from which there was free bleeding The first physician called closed the wound with several stitches and dressed it Healing took place by first intention but the lids remained red and swollen The eyeball was displaced forward, downward and inward, and was capable of only very slight movement in all

directions. There was no sign of fracture of the orbit. On examination the eye itself was found to be perfectly normal. The gland was removed and the patient made an uneventful recovery. The eye presents no deficiency of lachrymal secretion and although the movements of the upper lid are very imperfect the palpebral fissure can be opened to the width of six millimeters. Movement of the eyeball is normal in all directions except upward, where it is limited to thirty degrees.

56. **Two Thousand Operations for Appendicitis.**—Murphy's article is a retrospective consideration of the subject of appendicitis based on 2,000 operations, with deductions therefrom. After a very thorough description of the surgical anatomy of the appendix the author proceeds with the clinical history of the *disease*. Foreign bodies were present in a little less than 2 per cent. of the cases. Fecal concretions were found in 38 per cent. The erosion produced by these objects produces an atrium for the admission of bacteria. The bacteria found were, in the order of frequency, bacillus coli communis, staphylococcus pyogenes aureus and albus, streptococcus, pneumococcus, bacillus tuberculosis and actinomycosis. Appendicitis is neither contagious nor infectious, although it seems to have family predilections. The symptoms in the order of their occurrence are (1) pain in the abdomen, sudden and severe, followed by (2) nausea or vomiting within a few hours, but most commonly between three and four hours after the onset of pain, (3) general abdominal sensitiveness, most marked in the right side or more particularly over the appendix, (4) elevation of temperature beginning from two to twenty-four hours after the onset of pain. When that order varies, Murphy always questions the diagnosis. If nausea and vomiting or temperature precede the pain he feels certain that the case is not one of appendicitis. When the temperature *alone* precedes the pain for a day or two, he fears that it is typhoid fever with a typhoid ulcer in the appendix. In not a single case was pain, usually colicky in character, absent as an initial symptom. It usually reached the acme of intensity about four hours after its onset and then subsided gradually in the *majority* of cases. With the cessation of pain, in cases where the pus was liberated from the appendix came diminution or cessation of absorption, but not necessarily a diminution or cessation of danger. He has never had a case of appendicitis without elevation of temperature. He does not consider leucocytosis of any value except as an indication of the absorption of septic products. Furthermore, infection may be present without there being any leucocytosis. The character of the pulse is of little value in the differential diagnosis of appendicitis. With reference to the clinical course of appendicitis, Murphy says that the inflammation may subside within a few hours by escape of the infected material along the tract of the appendix into the cecum, that it may subside as a circumscribed inflammation of the appendix, that it may form a circumscribed infection without the production of *pus in the free peritoneal* cavity, that it may subside as a circumscribed abscess outside the appendix, rupture through the wall of an adjacent coil of intestine and empty itself in that way, that it may subside as circumscribed peritoneal abscess and remain quiescent to be opened later, *that it may terminate in a circumscribed or diffuse general* suppurative peritonitis, that thrombophlebitis *of the iliac veins and general* embolism, portal thrombosis, hepatic abscess, *extension of the inflammation into the pelvis, behind the peritoneum, around the* kidney, liver and gall bladder, *into the* subphrenic space, through the diaphragm into the *lung or into* some portion *of the urinary* or genital tracts, are possible methods of termination. The *time for* operation is divided *into four* stages: 1, within the first forty-eight hours, 2, from the second to the fifth day, 3, from the fifth or seventh day *on*, 4, in the intermediate stage—between *attacks*. He advises operation on every *patient* who has been through an acute attack of *appendicitis*. In this class of cases he has had only one death *in 1,300 or 1,400* operations, the result *of* an acute infective peritonitis traceable to an interne who had without Murphy's knowledge made a postmortem on a *post* abortion peritonitis the night before the *operation*. The type of operation and the subsequent management of the cases are described in detail, but Murphy's methods are sufficiently well known so as not to necessitate detailed reference to this portion of the article. The mortality varies considerably when it is studied in groups of 100 cases. The greatest mortality was in the first 100 *when it reached 11*. The number of deaths *in each 100* then gradually decreased until after the meeting of the American Medical Association in Atlanta in 1896, when a great cry was raised against peritoneal operations *and* particularly against the *frequent operations* for appendicitis. General practitioners hesitated before advising operation, and consequently the mortality rate increased in the year following this meeting, reaching 7 in 100. Then there was a gradual decline as the error of the position was recognized, *until a* second epidemic of so-called conservatism (expectant treatment) passed over the country and the mortality reached 6 in 100. For the last four years there has been a steady decline in the number, until in the last 100 operations there was a mortality of only 2 per cent. One of these deaths was due to an ileus of the small intestine high up, bearing no relation to the appendical operation, and the other a death from a double pneumonia six days after the operation for general septic peritonitis of appendical origin. Every death from appendicitis is the result of not calling in a physician sufficiently early after the onset of symptoms, or of dilatoriness on the part of the physician and surgeon in not acting promptly when they are called. There is no plan of medical treatment which will lower the mortality in appendicitis. The physician can make an early and accurate diagnosis and he is not justified in deferring operation because the final results in appendicitis as a whole, are very gratifying. The surgeon should conduct a case of appendicitis to a favorable termination with the least hazard or risk to the patient, regardless of his personal or professional feeling. A second operation with a living patient at the end is better than a primary radical operation with a mortality of 2 or 3 in a hundred as the price. The man who is having more than three or four deaths in a hundred operations is either receiving his patronage from incompetent *and* procrastinating medical men, or he is doing too much manipulating in the peritoneal cavity under unfavorable pathologic conditions.

58. **Study of the Tubercle Bacilli.**—Smith says that no observations have thus far been presented which invalidate the distinction between the bovine and the human variety of tubercle bacilli made by him in 1898. Since then he has made three cultures from the mesenteric lymph glands of human beings, studying them from these points of view best adapted to inform us whether they are of the bovine or of the human variety. The bacilli isolated from these three cases of presumable food infection do not correspond to the bovine type of tubercle bacilli in any one particular. They were cultivated readily from nearly all the guinea-pigs inoculated, and grew luxuriantly from the start on dog serum. Subcultures on glycerin *agar and* glycerin bouillon grew vigorously after the first transfer from dog's serum. Morphologically, the bacilli were either fairly long, averaging about 2 microns in

length or they were very variable The uniformly short, straight forms of the bovine type were absent In all cases the bacilli were of a very low order of virulence, lower even than that of many of the cultures of human origin studied heretofore We have as yet no satisfactory evidence concerning the degree of change if any which tubercle bacilli of bovine type may undergo in the human body That changes could be as thorough going as would be the case if we were inclined to attribute these cases to infection by way of the digestive tract through milk is at present quite inconceivable and we must content ourselves to referring them to infection with bacilli of strictly human origin

61 **Chronic Internal Hydrocephalus**—According to Taylor my method of drainage, done with a view to relieving internal hydrocephalus in order to be successful must be internal slow prolonged or permanent It would seem as if a small permanent fistula between the ventricles and the subdural space would most closely resemble normal conditions and in the hope of attaining that end six cases were operated on as follows under general anesthesia An osteoplastic flap about two inches in diameter is turned down with its hinge over the base of the mastoid and just above the level of the horizontal lateral sinus In the lower part of the dura mater thus exposed a semicircular flap base downward and about one inch in diameter is made Care must be taken not to injure any distended veins as their walls are so pliable that neither clamp nor ligature is of much use, and the bleeding is annoying A slender aspirating needle is passed through the second temporo sphenoidal convolution which usually protrudes inward and slightly upward until it enters the ventricle when the clear fluid spurts out and is collected in a sterile tube for bacteriologic examination Only a very small amount should be allowed to escape in this way The drain is now made of No 2 forty day chromic catgut Three loops (six strands) about an inch and three quarters longer than the thickness of the brain are bound together by a loose spiral of catgut starting at one end and stopping so as to leave an inch and a quarter of the loops free Around the shaft of the drain but not covering its tip are rolled three layers of cargile membrane With a long narrow bladed thumb forceps the tip of the drain is seized and carried into the ventricle along the tract made by the aspirating needle The tip projects about one half inch into the ventricle The free loops of gut are slipped under the dura, between it and the brain surface in different directions but chiefly downward toward the great lymph spaces at the base of the brain A sheet of cargile membrane is slipped between the dura and the catgut loops to prevent adhesions The dura is sutured with catgut the bone flap is held in place by three or four chromic catgut sutures the deeper soft tissues by catgut, and finally the skin with silk A good sized sterile dressing is applied with some pressure After the first twenty four hours there is no further external escape of ventricular fluid Two of the cases so operated on are still living twenty and eleven months respectively Although there is little improvement in their physical condition the betterment of the mental condition is quite marked One case lived two months and died of acute gastrointestinal disturbance Another died about sixty hours after operation and unquestionably as the result of it Another case developed an otitis media on the fourth day then anuria and died on the eighth day The last case died suddenly on the sixth day when it had apparently been recovering slowly from the sharp reaction of the first three days That prolonged drainage can be obtained by this method seems demonstrated by the first two cases It is interesting to note that in both cases the drainage became most active about two and one-half to three months after operation The operation to attain its best results must be performed early before irreparable damage has been done to the brain It must be brief to avoid shock inflict the least necessary traumatism to the brain permit of the escape of only a little ventricular fluid so as to avoid any sudden change in the hydrostatic condition of the brain The after treatment of these cases resolves itself into a problem of medico pedagogical training

69 *The Boston Floating Hospital Robert W Hastings
70 The Immediate Repair of Injuries of the Perineum Received in Childbirth Ernest W Cushing

69 **The Boston Floating Hospital.**—Hastings describes this unique hospital, which has been in existence since 1894 The vessel used, a barge, has three decks The lower deck and the main deck, except the cabin in the stern, are used for the machinery, tanks crew's quarters and the navigating appliances The stern cabin is used as a ward and contains 15 cribs The open space on this deck serves as a dining room The kitchen storeroom babies food department, refrigerators, a small operating room, linen room and one or two offices are also located on this deck A small open space is used by guests twice a day for a kindergarten The largest ward on the boat has beds for 21 children Another ward, intended for chronic, generally tubercular cases, has 4 beds Another ward has 15 beds, a total of 53 beds The upper deck is used almost entirely by day patients, who come at 9 in the morning and leave at 4 in the afternoon Over 30 nurses and from 10 to 15 doctors and medical assistants take care of the patients The medical staff consists of a visiting and a consulting staff a resident physician two assistant resident physicians and an externe Six medical assistants are assigned—two to each of the medical services and two to the out patient services The nurses are all graduates and work for a merely nominal wage because of the experience they can get and the course of lectures which is given each year by the staff Satisfactory practical work and the passing a written examination based on these lectures entitles them to a diploma Two hundred and ten patients were treated in 1903 in the permanent wards, each one staying an average of 17 2/3 days The death rate was about 23 per cent, while 46 per cent were discharged well Of the 50 patients who died 16 were moribund at entrance and survived less than 48 hours Four hundred and ninety eight patients remained for the day only, many of them making ten or twelve trips day after day Of these 272 left well while 110 others were greatly relieved An abundance of pure fresh air is the essential element in the treatment of the cases, although this is supplemented by food, care and a little medicine The milk used comes directly from the Walker Gordon farm and is delivered within four hours after the time it is milked A so called 'atmospheric plant" supplies fresh air on days when the humidity is very high Air is taken from the upper deck carried over coils of brine, kept at zero temperature, and the moisture contained in it is frozen out This dried air is then warmed by a steam coil and blown into the wards By this means an even temperature of about 68 F and a humidity of about 50 per cent is maintained The vessel is towed out into the harbor at 9 30 a m and remains there until 4 30 p m

7 Volunteer Brigade Medical Unit P B Giles

2 **Trypanosomiasis**—Bruce lays down certain propositions, the result of his observations 1 That the trypanosoma found in the blood of natives on the west coast of Africa and in Uganda, and those found in cases of sleeping sickness, are identical 2 That the so called "trypanosoma fever" is nothing but the first stage of sleeping sickness 3 That neither the native nor the European is immune to this disease 4 That as regards prognosis, instead of being favorable, the mortality is 100 per cent in both the colored and the uncolored races, at the same time a percentage of the natives who have trypanosomes in their blood may kill off these trypanosomes before the disease has given rise to the pathologic changes which constitute sleeping sickness 5 That up to the present no evidence has been brought forward to show that any of the lower animals take any important part in the spread of human trypanosomiasis 6 That human trypanosomiasis is conveyed from the sick to the well by means of a biting fly—the *Glossina palpalis* 7 That several members of this genus are also able to convey the virus from the sick to the healthy 8 That there is no proof that other genera of biting flies carry the infection under natural conditions 9 That there is no proof that *Trypanosoma gambiense* passes through any metamorphosis in *Glossina palpalis*, but that the transference of the parasites by this fly from one animal to another is purely mechanical 10 That all the stages of development of the *Trypanosoma gambiense*, so far as is known, take place in the human host 11 That measures for the prevention of the spread of sleeping sickness should aim at preventing, as far as possible, the movement of natives from sleeping sickness areas into any part of the country where any species of tsetse fly is found, the evacuation, if possible, of those areas, the destruction of the breeding places of the tsetse fly and of the fly itself, whenever possible

4 **Cerebrospinal Fluid in Trypanosomiasis**—Christy studied the cerebrospinal fluid obtained by lumbar puncture in 104 cases of sleeping sickness, and presents the following provisional conclusions 1 That in many cases the trypanosomes never find their way into the cerebrospinal fluid, and in those cases in which they do, they are more frequently to be found toward the end of the disease 2 That the commencement of the fever or other symptoms is in no way correlated to the entrance of the parasites to the cerebrospinal fluid 3 That a large number of trypanosomes in the cerebrospinal fluid is rare, that when it does occur there is usually an access of temperature 4 That the parasites may come and go in the cerebrospinal fluid as in the blood 5 That enormous numbers may appear in the blood without appearing in the cerebrospinal fluid, and to some extent, vice versa 6 That when trypanosomes are present in the cerebrospinal fluid, its white cell elements are apt to be increased 7 That in cases where the parasites gain access to the cerebrospinal fluid early in the disease, mania and other head symptoms are more likely to be prominent

9 **Hernias of Children**—Corner discusses the pathology and treatment of the hernias of children and endeavors to throw light on the origination, the treatment, and the after effects on adults Childhood is the time when an operation has the best chance of curing a hernia, as then and then only is the

surgeon's skill aided by Nature in the subsequent growth of the subject For the treatment of the hernias of infants or children, he suggests the following Treat with dieting, rest in bed, if necessary, a light truss, and gray powder or the like, all hernias up to the age of four or five years The selection of this time is quite arbitrary and the proper age limit must be selected for each individual subject Female children can naturally be treated with more effective trusses than male Exceptions must be made from the following (a) large or uncontrollable hernias, (b) irreducible, perhaps difficult reducible or incarcerated, hernias, and (c) strangulated hernia In these it is better not to delay operative procedures Many of the difficult reducible hernias of children are caused by the cecum on the right side sliding into the hernia sac without a complete peritoneal investment This condition is called hernia en glissade At the age of four years, or thereabouts, all hernias of children should be submitted to operation unless there are special circumstances *Particular mention may be* made of (a) those with a congenital sac (the operation is now performed at the age of election) (b) those with an imperfectly descended testis and (c) those which have been and apparently will be persistent in character If more attention is paid to the diet and the persistence of abdominal distention of children the advisability or not of operative interference for all hernias in children which are persistent or of which the subjects are above the *age of 5*, the diagnosis between the acquired and congenital hernia sac, and *active* treatment adopted during childhood far fewer adults would be handicapped by hernia

14 **Medical Treatment of Deep Seated Hemorrhage** —Hare reduces the blood pressure in the bleeding area by promoting the fall of the general blood pressure through widespread vasodilation, and the administration of amyl nitrite by inhalation It is applicable not only to cases of hemorrhage from some part of the systemic circulation, but also to pulmonary hemorrhage Five consecutive attacks of hemoptysis occurring in four patients were all stopped instantaneously by amyl nitrite inhalation

2" On the Present Status of Suprapubic Prostatectomy for Enlarged Prostate J W Thomson Walker

17 **Treatment of Syphilis** —Hutchinson describes a plan of treatment invariably pursued by him as follows A pill is prescribed containing 1 gr of gray powder and one of Dover's powder, and this the patient is to take after meals, and only three times a day at first If no diarrhea follows after a few days, the pill is to be given, four, five or six times a day All soups, fruit, and green vegetables are forbidden, and the patient is told that the treatment and the precautions must be continued without any intermission whatever for one year at least An alum mouth wash is ordered to prevent ptyalism The patient is allowed to continue his ordinary avocations, but is advised to spend as much time in bed as possible If there is debility, a grain of quinin is added to the pill Under this plan it is very rare to see any symptoms either in the throat or on the skin Hutchinson never begins the treatment until the character of the sore is definite In some cases it is necessary to send the patient to the seaside, and sometimes, when extensive ulceration is present, iodid of potassium is given in a fluid dose to be taken together with the mercurial pill He regards the iodids of mercury as much less manageable than are the two given separately As a rule the iodids are avoided in all early stages

28 Résumé of Practical Deductions from Our Recent Knowledge of Suppuration of the Labyrinth Dundas Grant

25 **High Frequency Currents in Deafness** —Connal has studied the influence of high frequency currents in the treatment of dullness of hearing and subjective noises in the ear *In all the cases selected other methods of treatment were in*effectual *The cases were of a class not readily influenced by* ordinary methods of treatment The types selected were (1) chronic dry catarrh of the middle ear with secondary labyrinthine involvement, (2) chronic dry catarrh of the middle ear without marked labyrinthine involvement, (3) sclerosis of the middle ear, (4) post suppurative conditions of the middle ear (the purulent process having ceased) leaving a cicatrix or a dry perforation with or without calcareous deposit in the tympanic membrane, (5) primary labyrinthitis (traumatic), (6) tinnitus without dullness of hearing In all the cases both ears were involved, one ear generally being worse than the other Results 1 Six cases No improvement in the hearing in any *of them In four the tinnitus persisted* two thought the noises were slightly lessened, but were not sure about it 2 Fourteen cases In ten, no improvement in hearing, one was worse, two noted a slight improvement in the hearing One patient said she heard much better, but the improvement was not appreciable by any tests applied Of the ten patients who complained of tinnitus, eight reported an improvement, two of these said they were very much better In one case the noise disappeared entirely in one ear for six weeks, when it recurred 3 Five cases One patient said she heard better, but did not respond to tests, four reported an improvement *in the hearing* confirmed with the watch, and improvement *in the tinnitus* 4 Seven cases *Four reported a* slight improvement in hearing, *and four of five who had tin*nitus reported improvement 5 One case No benefit 6 One case No benefit The author urges the importance of technic in the electrical treatment of these cases The common method of applying the current is by means of the effleuve (or spray) This method was adopted in the earlier cases, but was found unsatisfactory The method of using a condensor electrode in each ear was substituted and gave better results probably because the current is more completely concentrated on the ears

30 **Treatment of Varicose Veins by Walking** —Marchais views on this subject were mentioned in THE JOURNAL recently page 287 He applies massage at first for two to four weeks This tones up the muscles and vessels and causes the absorption of the edema The varicose subject should not stand nor walk slowly What Marchais advises is a rapid walk, 100 steps to the minute, stopping short at the first *symptoms of* fatigue, then continuing when well rested *In case of recur*rence of pain or edema, *massage should be resumed. Elastic* stockings and hot baths should be *prohibited, but cold tonic* baths are useful *His results with 22 patients confirm the* efficacy of this *mode of treatment.* Lucas Championnière confirms *it, and applies the same* principle in the treatment of phlebitis after subsidence of fever He is convinced that immobilization favors embolism and cites 4 cases in his experience in which fatal embolism occurred during immobilization of a fracture He has his patients remain in bed after operations *for varices, but leaves the legs free* None of his patients with phlegmasia alba dolens is immobilized and all recover with surprising promptness

32 **Therapeutic Action of Radium** —Raymond and Zimmern have found that radium has a *remarkably soothing action on* the element of pain in certain nervous affections This effect

was particularly noticeable in tabes. The improvement and relief was marked after a few exposures. They found that the Roentgen rays also displayed great efficacy in this respect. They used a small quantity of pure radium bromid. No effect was perceptible in the merely functional neuroses. The results were also negative *in a case of facial paralysis and one of facial neuralgia* but in tabes, the lightning and lancinating pains *vanished as it by magic. In 4 tabetics thus treated* the application of the radium tube for four minutes banished the local pains.

35 **Chemical Analysis of the Urine.**—Labbé states that a rational interpretation of the findings in the urine is possible only when the intake of salt, etc, is known. No arbitrary standard can be established. To say that the amount of salt normally eliminated is 10 to 12 gm a day may happen to be true for a certain individual one day, but is liable to be erroneous the next day when he takes more milk than usual or his cook has been too generous with her seasonings. The chemical findings are of import only when the ingesta and the excreta are compared. A healthy individual normally eliminates exactly as much material as he takes in. The human machine is only a transformer of energy. The salts and the nitrogen are found in the urine in approximately the same proportions in which they were ingested. Analysis of the urine imparts *no information in regard to* the carbohydrates and fats, the products of whose final transformation are eliminated by the lungs.

36 **Cure of Varicose Veins by Intercurrent Phlebitis.**—Poulain has observed a case in which the varicose saphena vanished as a result *of a grippal phlebitis.* The indurated vein was replaced by a groove perceptible to the eye. The leg presents occasionally slight *edema near* the ankle, it tires more readily during a long walk, and there is once in a while some formication. *These are the only traces left of the extensive* varicose enlargement and severe phlebitis. The complete obliteration of the superficial veins seemed to have a favorable influence in this case.

38 **Prophylaxis of Tetanus with Pulverized Serum.**—Letulle washes out *the wound* with boiled water for fifteen minutes and then dusts it thick with dried, pulverized antitetanus serum and covers with gauze. This treatment is repeated every day until healing is complete. This mode of prophylaxis is called the "Calmette method" and *Letulle urges its general* adoption.

39 **Surgical Treatment of Gangrene of the Lungs.**—Auvray reviews *the international* literature on the subject and states that the post-operative mortality has been only 40 per cent *in the last series of 63 cases of gangrene of the lungs treated* by surgical intervention. Tuffier's last 11 cases have had a mortality of only 36 per cent. *The operative mortality* is less in case of gangrene consecutive to pneumonia or bronchitis or their combination than when it is consecutive *to bronchiectasia,* foreign bodies, wounds, embolism or perforation of the esophagus. Patients seen again *a few years afterward have* been found normal or, in a few instances, the shape of the thorax was *somewhat altered* and respiration slightly affected. The remote results depend, of course, on the character of the causal affection, a chronic process seldom permitting complete restitution. With such a process both lungs are usually more or less degenerated. Treatment should be early and extensive pneumotomy.

43 **Impressions of America.**—In this interesting summary of his hurried trip through America, *including Quebec* and Mexico, Faure comments on the famous marble operating room at Mount Sinai Hospital, New York, as the handsomest he has ever seen with its marble doors, but as a useless prodigality. He does not think the American operating tables compare favorably with the French, while the American instruments for general surgery and gynecology impressed him as heavy, primitive and sometimes even coarse. He says that instruments of this kind, to be delicate, supple and strong, have to be made by artists working with brain as well as hand and can not be turned out by machinery. He makes the statement that in America "the free hospital—*the hospital for the* poor—does not exist, perhaps because there are not many *poor people, or at least everyone from the richest to the* poorest considers it natural and legitimate to pay for the care he receives and the time devoted to him. Another reason may be that the towns are, many of them, too new for an official 'assistance publique' to have been organized." He comments with decided approval on the system of having rooms for rich paying patients under the same roof with free wards, a custom which he hopes will be introduced in France. The union of hospitals with politics here he qualifies as deplorable, much preferring the French system of *competitive examinations* with all its defects.

48 **Langerhans Insufficiency.**—Lesions in the islands of Langerhans have been found in 150 out of 167 diabetics examined from this point of view. Thoinot and Delamare found them in their cases of lean diabetes, not in the 'fat' variety, nor in the pancreas of 10 control subjects with various affections. They are not found in nervous diabetes nor in toxic glycosuria. These lesions are frequently associated with lesions of the other parts of the gland, but are sometimes the only lesions to be detected. The explanations offered by various writers do not withstand scrutiny except the theory that certain cases of diabetes are the manifestation of insufficiency *of these islands of Langerhans. This suggests the possibility* of an effectual organ treatment of such cases, using an extract of the tail of the pancreas from young animals.

49 **The "Academy for Practical Medicine" at Cologne.**—An important innovation has been introduced into Germany in the inauguration of these new "academies." They are *intended* to serve as centers for postgraduate instruction. Cologne leads, but will soon be followed by Frankfort, Düsseldorf and other *cities* where there is no university. The innovation is regarded with some apprehension by the general practitioner, fearing that it *may* cut into his sphere of activity, but the city authorities affirm that they were impelled to this step by the interests of *the* medical profession *and* by the growing conviction of the importance of this profession for the general welfare. These convictions have impelled the city authorities to exact contributions from their fellow citizens in order to promote the further professional perfecting of physicians that they may better serve the general welfare. The aim of the new "academies" is to utilize for postgraduate instruction the vast material in the hospitals no [illegible]

to waste in many of the cities They do not aim to train specialists, but they hope to render the general practitioner proficient in the specialties The plan of organization tentatively adopted has four departments in view the training of newly fledged M D's during their compulsory year as "praktikants," postgraduate training of established physicians, training in specialties, and promotion of scientific research

56 **Prevention of Fever in Parturients** —Zweifel shows that all the modern efforts for asepsis in maternity cases have not resulted in any decrease in the number of febrile cases The mortality has been wonderfully reduced, but the number of patients developing fever has not been materially diminished He thinks that the principles of surgery should be applied more to obstetrics, especially the principle of wiping the parts dry of blood He noticed that one or two small clots of blood usually lurk in the recesses of the vagina, and thinks that decomposition of these clots is sufficient to explain the febrile course If a woman is examined half an hour to an hour after delivery of the after birth, one or two clots as large as a walnut, will almost invariably be discovered in the fornix vaginæ He removes these clots with a dry sponge as they are in any event entirely superfluous and may cause trouble as they decay All his lying in patients have been wiped dry in this way since last October, the operation done with rubber gloves The percentage of febrile cases dropped at once after this innovation was introduced so that in 94.3 per cent of all the normal maternity cases the temperature was normal throughout a result never before attained There were only 14 febrile cases in 243 births and, in fact, only 3.3 per cent developed fever which could be attributed to the genital tract out of the total 5.7 per cent febrile cases During the few weeks in which the vagina was wiped dry without gloves the proportion of febrile cases increased During previous years the proportion of febrile cases has ranged from 32 per cent in 1890 to 21.4 per cent in 1901, and 16.2 per cent in 1903, the average for the nineties being 28.34 per cent and from 1899 to 1903, 19 per cent The reduction since 1899 followed the introduction of gloves The pathogenic germs can readily find their way from without to these clots lurking in the vagina, and might easily originate fatal infection in them Hence it follows that the wiping away of all clots of blood should be regarded as one of the routine prophylactic measures in maternity cases It should always be done under dry asepsis, and by the physician Zweifel adds that irrigation of the vagina before or during delivery is always superfluous and liable to be dangerous, but this dry wiping away of the blood is an important, decided forward stride in the prevention of puerperal fever

57 **Intraperitoneal Shortening of the Ligaments with Catgut** —Menge considers every backward displacement of the uterus as necessarily pathologic He fastens the uterus in an approximately normal position by taking up a loop in each round ligament and suturing this loop with a row of stitches down the middle to make it solid He then brings the ends of the loops together and sutures them firmly to the uterus underneath The loop is taken in the part of the ligament close to the uterus, and a single fine catgut thread is sufficient to insure solid fixation The operation is particularly useful after wedge shaped excision of the tubes the loops of the ligaments being folded over the wound in raw surfaces The technic is fully illustrated

58 **Physostigmin After Laparotomies** —Vogel's experience with physostigmin as a preventive of post operative ileus has been very favorable He has been using it for three years injecting .0004 gm physostigmin three or four times during the day giving the first injection before the patient leaves the table, and supplementing it later with a glycerin enema if necessary When ileus has developed the physostigmin may be tried but should not be forced

60 **Vulvar Edema and Laceration of Perineum** —Sittner explains edema of the vulva as a natural process to protect the perineum against laceration The vulvar ring is enlarged and the tissues become more elastic

62 **Gravidal Psychosis Cured by Induced Abortion** —Treub's patient was a ii para in the fourth month She had been reading Victor Hugo's 'Notre Dame de Paris,' and had become convinced that the child she was bearing would prove to be a monster Her psychosis was so pronounced that she tried to commit suicide to destroy the monster, and Treub finally induced abortion which was followed by complete recovery

64 **Restitution of Vagina by Transplantation of Anus and Rectum** —Twelve years ago Sneguireff reported a case of this kind The result of the operation was complete and permanent Coitus has been rendered apparently normal and the artificial anus made in the place of the excised coccyx functionates normally He does not know of anyone's having repeated the operation, but its perfect success encouraged him to try it again in 2 cases during the last year or so in which it was indicated The patients were young married women who had never menstruated although the molimen recurred regularly and one had vicarious epistaxis This one applied immediately after her marriage to know why coitus was not possible In the other patient the urethra had been used unwittingly in place of the vagina and she applied only for relief from a laceration of the urethra The vagina in each case was merely an inch deep recess The operation was done under ether the coccyx was removed the rectum was mobilized brought out through the incision and cut across The edges of the lower stump were turned in and sutured together to make the top of the new vagina The proximal stump was sutured to the skin embedded in the muscles in such a way that the fibers of the levator ani co operated in the functioning of the new anus which was in fact the sphincter ani tertiu

The pelvis was then raised, and through the natural anus the wall dividing the rectum and anus from the vagina was incised, the mucosa lining of the vagina was sutured to the mucosa lining of the rectum and anus. The incised anus thus sutured to the small orifice of the vagina presented a striking resemblance to normal aspect and conditions. Defecation was suppressed for six days, then castor oil was given and the sutures removed. The new anus was incontinent at first, but after a month formed feces could be retained and evacuated at will in the first case, and in less than three weeks in the other. The results of the operation have realized all that was anticipated. The three steps of the operation are shown in diagrams.

65. **Management of the Arms During Narcosis.**—In all vaginal operations Torggler crosses the arms of the patient on her breast, the hands touching the elbows, and draws up the front of the chemise over them, tucking it in above the arms. This holds them and prevents nerve paralysis from compression at any point. During ten years of experience he has had but a single chloroform death in 806 narcoses, and this was a purely heart accident occurring before the narcosis had really commenced.

66. **Weighting the Compresses for Laparotomies.**—Bircher fastens a small weight—2.5 to 3 gm.—to one corner of each compress, using a stout linen thread for the purpose, about a foot long. As the compress is used in the abdominal cavity, the weight is tossed to the length of the string and lies on the operating sheet. He has been using this device for ten years and has never failed to recognize and remove every compress without dread of any having been left inside. He criticises Kreutzmann's method as too laborious and time wasting.

67. **Laparotomy Technic.**—Gottschalk advocates in operating to draw the tumor or organ being operated on out of the abdominal wound and close the incision behind it as far as possible. The weight of the tumor will aid in detaching it. He insists that the surgeon should ask himself in every case whether it is not possible to close the abdominal cavity as soon as the tumor is drawn out instead of waiting until later. Also that the operation should be done outside of the abdominal cavity as far as possible. He describes in detail a case of myomotomy with amputation in the collum performed under these principles. They obviate the necessity for raising the pelvis.

69. **Prevention of Puerperal Fever.**—Mueller endorses Zweifel's remarks, cited above. He goes still further and advocates removal of all clots of blood from the uterus itself, as well as from the vagina. He accomplishes this with what he calls a "scraping rinsing catheter." It consists of a stout metal tube, the tip surrounded by a comb with wedge shaped incisions, the outer edges slightly rough like a file. By twisting this tube, in contact with the walls of the uterus, all the clots of blood and scraps of membranes are detached from the walls of the uterus and swept out by a stream of hot water turned on through the tube. The instrument thus combines the removal of all scraps and clots liable to decay, with mechanical stimulation, and the action of heat in the hot rinsing. He has been using it for three years and has been delighted with it. He has not had occasion to tampon the uterus on account of hemorrhage or apply compression, except in a few rare instances since he has been using this scraper. He adds that puerperal fever is sometimes due to decay of fecal masses, and advises energetic castor oil purges and repeated high enemata as a means of preventing infection from this source. He classifies his febrile cases as those which can be cured by energetic purgation and those with fetid lochia which can be cured by energetic rinsing of the uterus. The class of cases which do not respond to these measures are the true septic puerperal fevers, due to some primary, previously existing pus focus in the appendix, annexes or elsewhere, which has been encapsulated and caused no trouble until disturbed and the walls broken down by the trauma of the birth act, or else to infection from without, due to the attendants or the patient herself. This latter cause is becoming rarer and rarer under modern methods. The physician should seek to discover and render harmless the primary focus, possibly resorting to intravenous silver injections according to Credé.

Bokelmann discusses the same subject but denounces Zweifel's views. He proclaims that the parturient woman should be regarded as a *noli me tangere*, and that the application of the principles of modern surgery to the physiologic process of childbirth is liable to be attended by the most serious consequences. He thinks that dry asepsis is unattainable in the normal vagina after delivery, while attempts to realize it throw wide the portals for infection. His motto is "The strictest asepsis for everything that comes in contact with the birth passages and strictest avoidance of every contact with the birth canal not absolutely required."

71. **Delivery in Eclampsia.**—Sippel has always been an advocate of expectant treatment of eclampsia, but his recent experience has converted him to the opposite view. He now proclaims that there is only one thing yet known positively in regard to eclampsia, and that is, that it is a consequence, a product of pregnancy. This being the case, the logical treatment is to remove the cause, that is, to put an end to the pregnancy.

72. **To Facilitate Puncture Through the Vagina.**—Flatau uses what he calls a "guide button" on the canula to protect the parts from injury. It is an elliptical, elastic ball which is placed over the tip of the canula. When the latter is forced into the tissues the ball slips back on the canula.

74. **Prevention of Postoperative Cystitis.**—The double catheter used in Israel's clinic is made in such a way that the inner tube does not come in contact with the walls of the urethra at any point, as it is not pushed out of the outer tube until the latter reaches the entrance into the bladder. It is thus possible to rinse out the bladder as frequently as deemed necessary, without fear of infection. In 34 cases of serious operations the bladder was thus rinsed from 6 to 21 times without a single mishap with the exception of one case, in which the vitality of the bladder had already been seriously compromised. He does not attempt to enumerate the cases in which the double catheter was used less than 5 times. He thinks that this principle of absolute asepsis and frequent irrigation is the right one for the prevention of post operative cystitis.

77 and 78. **Intraperitoneal Shortening of the Ligaments.**—Kleinwächter criticises Menge very sharply for announcing as new the method of surgical treatment of retrodisplacement of the uterus briefly outlined in abstract 57 above. Kleinwächter reproduces the cut from Palmer Dudley's article, published fourteen years ago, in which the latter describes what is essentially the same operation. The only difference seems to be in favor of Dudley's technic, namely, that a larger surface is freshened. Kleinwächter sarcastically comments that it is usually expected that a specialist and especially a professor should be thoroughly posted in the history and literature of his specialty. Professor Menge, he adds, is proof of the fact that there are exceptions to this rule. In the following article Beck of New York claims priority for the operation recently promulgated by Bardescu, mentioned on page 686 of the last volume.

80. **Sterilization of Catheters.**—Gusseff uses an ordinary nickel tube to hold the catheter. One end has four holes bored through it, through which 2 wires are passed at right angles, forming a support for a wad of cotton which keeps the catheter from dropping out. The other end of the tube is stoppered with cotton. These tubes are inexpensive, never break or wear out, and there has not been a single case of infection in more than 4,000 catheterizations in which the catheters were sterilized in these tubes. A dozen or so of the tubes at a time are placed in the autoclave together. After the catheter is used, it is boiled in soda solution with the tube, fresh cotton is put in, then the catheter and the stoppered tube is placed in the autoclave.

81. **Hebotomy or Extramedian Symphyseotomy.**—The particulars of the 4 cases in which van de Velde has performed this new kind of symphyseotomy are related in detail. He

styles the operation extremely simple, typical, rational, convenient, with little trouble for the patient, a really ideal operation, and the only one able to save the child alive in many cases" One of his first patients has passed since through a normal pregnancy and delivery, the pelvis having been so enlarged by the hebotomy that delivery proceeded normally The operation has not affected the gait in any instance He coins the word hebotomy from the Greek term for pubis The previous notices of the operation will be found on page 133 of vol xl and 231 of vol xxxix

86 Critical Review of Recent Publications on Infant Feeding H Finkelstein—Sammelreferat.

83 **Treatment of Tendency to Kidney Stone Formation**—Klemperer believes that it is possible to prevent stone formation in the kidneys by appropriate dieting When dieting is inconvenient the same results can be attained with alkaline mineral waters used copiously, or even with artificial substitutes for the mineral waters He tabulates the results of a number of clinical and experimental researches which sustain these assertions in regard to urate concrements The oxalates are dissolved when 2 gm magnesium sulphate are given once or twice a day with a mixed diet. He advises giving 5 magnesium sulphate four times a day when vegetables or milk or eggs are being copiously eaten This serves to prevent oxalate crystallization. Mineral waters are also useful but by no means to the same extent as with the urates Phosphate concretions are generally due to overexcitability of the nervous system, entailing gastric hyperacidity His researches have also shown that already formed concrements can be dissolved by the copious use of mineral waters A course at a watering place is not at all necessary if the required hygiene is followed at home In any event, the hygienic and other measures must be kept up for years or one's entire life, to ward off threatening trouble from this source Cystin stones are the expression of a constitutional anomaly in the metabolism, like diabetes and the tendency to their formation should be combated by the usual measures and restricting the albuminoids in the diet to such as contain little, if any, preformed cystin Egg and plant albumin contains much less cystin than serum albumin and fibrin

84 **Local Application of Heat**—Jerusalem relates his favorable experiences with dry hot air applied to the treatment of erysipelas and streptococcic phlegmons He thinks cold applications are contraindicated in case of inflammation, citing Bier, who proclaims that cold applications are liable to transform an acute and curable process into a chronic, incurable one Warmth is always agreeable in case of inflammation, and is actually the best analgetic at our command It has also displayed remarkable power as an analeptic and absorbent Thermophore compresses are the most convenient, but heated dry cloths or bags of sand are equally efficient Phlegmons on the limbs have been effectually treated with prolonged local baths as hot as the patient can bear

91 (No 31) *Comparative Value of Natural and Artificial Infant Feeding for Animals H Brüning (Leipsic)—Vergleichende Studien über den Wert der natürlichen und künstlichen Säuglingsernährung bei Tieren

87 **Roentgen Views of the Base of the Skull.**—All the parts of the base can be skiagraphed, but they require frontal, sagittal axial or oblique exposures for varying conditions Most of the anomalies in this region show up well and Roentgen examination is a valuable aid in diagnosis Two fine nearly life size skiagraphs are given, one of a normal and the other of a cretin man The differences are striking and characteristic

88 **Influence of Collargol on Bacteria Accompanying Tubercle Bacilli**—Behr writes from a tuberculosis sanatorium to describe his experiences with 14 cases of tuberculosis treated with collargol to control the mixed infection He was impressed with the way in which the pyogenic germs accompanying the tubercle bacilli were influenced by the collargol, which displayed marked therapeutic action in this respect The tuberculous process was also favorably influenced, but as this result is always obtained in the sanatorium, he does not venture to ascribe the benefit in this respect to the collargol Further tests in this direction should be instituted in dispensary treatment of tuberculosis where the patients remain in their usual environment In 7 out of 10 patients the number of cocci in the sputa was found very much reduced, the sputa also diminished He administered the collargol by the mouth and rectum buying 100 gm in substance and dissolving it in distilled water to make a 1 per cent solution He gave one tablespoonful of this twice a day, supplemented by 30 c c given per rectum Each patient thus received 5 gm silver per diem This was kept up for one to eight weeks in 14 cases with an average of seven weeks, or 110 days

89 **Relations of Alcoholism to Surgery**—Polak remarks that the number of drunkards is comparatively limited in Bohemia, the official records showing only 4 to each thousand inhabitants Nelson's figures report 1 to each 145 inhabitants in England Polak argues that the surgeon must be versed in the detection of acute and chronic alcoholism, as it has such a marked influence on the outcome of his work, and he should know how to combat it If a very tipsy subject requires surgical intervention at once, he should be prepared by copious lavage of the stomach, caffein in case of weak heart action and, in case of insufficient respiration, it should be promoted artificially and 002 gm atropin be injected several times Tepid baths with cold water poured on the head and back of the neck are also useful In chronic alcoholism the surgeon has to distinguish between the three stages In the first he has to anticipate only a somewhat severer and stormier narcosis, and the tendency to fat in the subcutaneous tissue sometimes interferes with primary healing The last stage, the 'premature senile" stage, is a contraindication to any major operation, as body and mind are too much countermined In the middle stage the resisting powers are weakened Narcosis of such a subject is likely to be a difficult affair, but it sometimes happens that after such a subject is once fully narcotized the operation can be continued without further use of the narcotic, as he lies tranquil without experiencing any special pain Polak reviews the experiences with alcoholics at Maydl's clinic at Prague He found that the wound suppurated in 7 per cent more of the alcoholic subjects than in the others and the mortality among them was greater, gangrene claiming 31 8 per cent , abscesses and phlegmons, 35 7, and erysipelas, 14 per cent., while the corresponding mortality among the non drinkers was from gangrene, 17 per cent abscesses 7 9 and erysipelas, 9 per cent. These infectious febrile suppurative processes are especially hard on drinkers A trophoneurotic hemorrhagic bladder affection was noted in one and the bones were found more fragile in them Fat embolism occurred in 2 He regards large doses of strychnin as the most approved means of curing the psychosis underlying dipsomania, citing Portugalow's experience of 455 drunkards cured with strychnin Delirium tremens is frequently brought on by traumatism and is always a very serious complication even with slight surgical injuries and operations

91 **Artificial Feeding of the Young of Animals.**—An interesting series of researches are here described showing the growth of young goats fed with sterilized milk according to the rules of infant feeding The various particulars are tabulated and compared with the growth of normal suckling kids The results confirm the theoretical views in regard to the incomparable superiority of the mother's milk for the growth of the young

92 **Treatment of Yellow Fever with Anti-ophidic Serum** — Rodrigues statements in regard to the efficacy of treatment of yellow fever with a serum made to combat the bites of poisonous snakes of Brazil have not been confirmed by the experiences of others Carlos Seidl and Marchoux and Simond gave the method a trial but met with negative results The first to suggest serum treatment of yellow fever was Professor Miguel Couto of Rio who treated several yellow fever patients with serum from convalescents His communication on the subject was published in the *Brazil Medico* of April 22 1892 Rodrigues reports rapid recovery of 21 yellow fever patients with but one exception under treatment with anticrotalic and antibothropic serum

94 **Cancer in Brazil** —This article by Professor Sodre, editor of the *Brazil Medico,* was presented at the recent Latin American Congress His figures show that cancer is comparatively rare in Brazil although at certain points the number of cases has increased during the last few years There is an unmistakable connection between the frequency of cancer in Brazil and the climate the number of cases varying with the latitude In the extreme north the equatorial portion of the country cancer is exceptional The number of cases increases toward the tropic of Capricorn and reaches its maximum in the extreme south where the climate approximates that of the European Mediterranean countries In Brazil cancer locates with marked predilection in the uterus Stomach and liver cancers are very much less frequent He gives a comparative table of the mortality from malignant disease in various cities of the world per 10 000 inhabitants In Paris this proportion was 11 8 in London 6 8 in Boston 7 9 in New York 6 2 while in Bahia it was only 1 9, and in the most affected center Rio de Janeiro only 2 8 In other tables he gives the same figures for the countries France heading the list with 9 8 per 10 000 inhabitants England with 7 6 United States 3 4 Tasmania 5 New Zealand 4 4 and Brazil 0 41

102 **New Remedy for Diabetes** —De Freitas announces that an indigenous tree the ironwood, has remarkable anti diabetic properties He uses an alcoholic tincture of the inner bark and reports its success in 8 cases of diabetes with sugar in amounts of 15 26 and 30 gm or thereabouts in the urine Examination a few days after taking the "pao ferro" showed entire absence of sugar in every instance The scientific name of the tree is the *Dialium ferrum* The uniformity of action observed in the 8 cases the complete cure and its permanence to date compel him to publish his results without waiting for further confirmation

Address.

REMARKS ON ADVANCES IN GYNECOLOGY DURING THE LAST YEAR, SENILE ENDOMETRITIS

CHAIRMAN'S ADDRESS BEFORE THE SECTION ON OBSTETRICS AND DISEASES OF WOMEN AT THE FIFTY FIFTH ANNUAL SESSION OF THE AMERICAN MEDICAL ASSOCIATION AT ATLANTIC CITY N J JUNE 7 10 1904

L H DUNNING, M D

INDIANAPOLIS

Before beginning my address, I desire to thank the members of the Section and to express to them my high appreciation of the honor they have conferred on me in electing me chairman of the Section for the year Mindful of the obligations resting on the chairman of this Section, I have used my best endeavor to advance the interest of the Section, and to assist in the preparation for this session of a program worthy of the occasion

If we have succeeded in this endeavor, a large share of the credit must be accorded to our secretary, Dr C L Bonifield His labors have been faithfully and efficiently performed, with perseverance and cheerfulness I commend his example to all future secretaries It will be observed on perusal of our printed program that we have been able to obtain twelve papers on obstetric subjects, besides several others which have an indirect bearing on the same subject For valuable suggestions relating to the arrangement of the program and assistance in obtaining obstetric papers, I wish to thank our esteemed member, Dr C S Bacon

THE PROGRESS OF GYNECOLOGY

It is not my purpose to indulge in extended remarks on the progress of gynecology during the last year, as master minds have already successfully undertaken the task of writing its history One seeming fact has impressed itself on me as I have studied this history It is that there has been less published than usual, during the year, relating to new operative procedures The year seems to me to have been one in which a large amount of successful surgery has been done, but one in which the struggle has been to seek out and find the best indications and methods There has been also much earnest effort to solve some of the difficult questions of etiology and pathology as they relate to diseases of women

These are right tendencies, and will assuredly appeal to right-minded persons everywhere There are still many difficult and important questions demanding solution at our hands, and it seems to the writer not inappropriate to indicate a few of them at this time Those mentioned may not be the most important but are such as have forced themselves on me during the progress of many years of active work as a general practitioner and as a gynecologist

Our method of treatment must be based on our ideas of etiology and pathology, so that the first effort of the gynecologist should be to discover, so far as possible every cause of disease of women, and to endeavor to obtain a correct understanding of the morbid processes existing in any given case, and in all cases Fortunately for the present age, the activities of physicians in the past have resulted in the establishment of a well nigh perfect classification of diseases, with a good nomenclature and a very clear understanding of the symptoms and course of the various diseases Our debt of gratitude to our predecessors is immeasurable As observers and classifiers of facts, the physicians of the past were fully equal to those of the present day They have, however left for us to solve many a knotty question, especially those relating to the causation of disease and the morbid processes induced by the same I do not need to cite instances You are familiar with them We have all witnessed the struggles to discover the cause of cancer, of epilepsy, of the development of neoplasms, of eclampsia of the growing sterility in the class of educated women And so, too, have we witnessed the efforts to find not only the cause but the pathology of painful menstruation, of the perplexing pain in the ovarian region usually denominated ovarian neuralgia, of the blighting of organs and the lack of co-ordination of the nervous system In each one of these morbid conditions, or distressing signs of disease, there is a fruitful field for investigation

Many of the sources of infection have been found their disastrous results ascertained, and the methods of prevention and cure are becoming known In the labors of Jenner, Pasteur, Koch, Lister, Tate and others, humanity has been greatly blessed They have not only been benefactors of the world, but have given our profession immortal fame McDowell's and Sim's names should be added to the list of benefactors The achievements of all these great men came not by chance but by deliberate effort In like manner shall appear the findings of the present and future physicians, for we discover that which we seek to find, more perhaps than we at first thought, for our vision enlarges and our understanding quickens as we advance

I have been incited to give utterance to these thoughts because of one or two pessimistic papers and a few remarks I have listened to during previous meetings of this section So long as the world stands there will be unsolved problems, and a suffering people waiting for their solution The moral is let each man find an unsolved problem within the scope of his attainments and then set himself deliberately and persistently to the task of its solution

SENILE ENDOMETRITIS

The scientific subject I have chosen to discuss at this time is "Senile Endometritis," and it is selected because I believe it has not received the attention at the hands of practitioners and authors its importance demands There seems to prevail a mistaken idea that endometritis affecting women before the menopause disappears after that period, and that should there be by chance a case prolonged beyond the climacteric, it is of little importance and easily cured Such is not the invariable rule It is true endometritis after the menopause is not of so frequent occurrence as it is during the childbearing period, yet is not uncommon, as evidenced by the fact that out of 161 consecutive private cases of disease of the reproductive organs recorded in my case-book, there are histories of 15 cases of senile endometritis of sufficient severity to bring the patients to a specialist for relief The complications of the disease are in the main different from those in the ordinary cases of endometritis Its course is more protracted, and the sufferings of the patients marked and characteristic, so that the writer believes senile endometritis should be treated as standing in a separate class

Clinically, we observe two forms of the disease, classified according to the intensity and duration of the inflammation, viz, the acute and the chronic The acute form results from primary infection or from an exacerbation of the chronic form of the inflammation I have observed a number of cases of acute senile endometritis, due to gonorrheal infection In these instances the vagina was involved first and later the endometrium In one case in which there was also mixed infection, the inflammation extended beyond the interior of the uterus into the tubes and ovaries and to the pelvic peritoneum Inasmuch as this raises a question which has not been much discussed heretofore, I have thought it best to introduce the history of this case It is as follows

CASE 1—Mrs A, aged 54 years The menopause occurred *four years previously* She was a large, finely developed colored woman who did not appear to be more than 45 years of age She came into my service at the City Hospital, Oct 15 1902 She complained of pain in the hypogastric and inguinal regions and had a vaginal discharge She confessed she thought she had gonorrhea, which had been contracted six weeks previously

Examination—There was slight fever, marked pain and systemic disturbance enough to confine the patient to the bed A vaginal examination showed only slight vaginitis, but marked endometritis, a fixed uterus and induration surrounding the uterus Dr W S Dodds made a bacteriologic examination of the vaginal and uterine secretions, demonstrating the presence of gonococci, streptococci and staphylococci

Diagnosis—Here, then, was a case of acute pelvic inflammation, due to gonorrheal and mixed infection, the infective material finding lodgment in the uterus, and there exciting an inflammation that extended to other pelvic tissues Two weeks after her admission an examination showed a marked improvement in the pelvic peritonitis and the prolapsed inflamed and agglutinated tubes and ovaries could be palpated A few days later it became apparent that pus had formed and was accumulating in the tubes or ovaries The patient declined to allow us to operate by abdominal section, but finally consented to permit us to aspirate the abscess in the right tube or ovary with a hypodermic syringe By this means we drew from the abscess several drops of pus, thus demonstrating the statement I have made in a *former paper*,[1] *that in acute* senile endometritis "there is a tendency of the inflammation to spread to the uterine appendages and the pelvic peritoneum, resulting in some instances in pus accumulations within the tubes and ovaries or leading to pelvic adhesion"

In the beginning of acute senile endometritis there is marked intensity of symptoms The chronic form of senile endometritis may be a prolongation of a former endometritis, in other words, it may be a continuation of an endometritis existing before the menopause An endometritis resulting from gonorrheal infection and progressing until the tubes and ovaries must be extirpated in consequence of purulent disease, is very prone to persist after the salpingo-oophorectomy, even though the uterus be most thoroughly curetted

When the inflammation so persists it is most distressing and retards convalescence So distressing and persistent is this post-operative endometritis that I have gradually come to the belief that where the endometritis is pronounced and has existed long previous to the operation, it is the better practice to remove the uterus also, when necessary to extirpate the appendages Unquestionably, chronic senile endometritis in the majority of instances is preceded by acute endometritis when it is not a sequel of an anteclimacteric endometritis

Retroversion of the uterus and suppurating fibroid tumors are recognized as predisposing causes of senile endometritis *Prolapsus of the uterus, because of the* congestion of the uterus dependent on it, and because of the exposed condition of the cervix and os, must be considered another cause So may be laceration of the cervix uteri also In the latter case not infrequently the diseased condition of the mucous membrane and deeper structures of the cervix furnish a suitable field for the rapid development of microbic action Because of the lowered resisting power of the tissues, together with the proneness of these senile tissues to degenerative changes, there is no strong barrier against inflammatory changes, due to the activity of the pathogenic bacteria A patulous os and cervical canal may in some instances afford ready entrance to infectious material introduced into the vagina The sources and nature of the infections in senile endometritis are those common to inflammatory diseases of this region Gonorrhea is not so frequent after the menopause, yet when it does occur it often runs a virulent course, involving an inflammation of varying degrees of intensity, the vagina uterus and bladder, and not seldom the rectum also The history of the following case illustrates a frequent course in such cases

CASE 2—Mrs B, aged 52 years, passed the climacteric twelve years previously She consulted me Feb 19, 1898, giving the following history She is the mother of six children, and has always enjoyed good health until two years ago when she became ill, complaining of frequent and painful micturition, vaginal discharge and an inflamed and eroded vulva

Examination—At the time of my examination there was but little swelling of the vulva, but an intense vaginitis and marked endometritis The patient complained of very distressing smarting, burning and itching of the external genitals A few weeks' *treatment of topical applications of* solution of nitrate of silver and astringent douches brought marked relief so that the vaginitis seemed very nearly well, but the endometritis persisted In this case the discharges were purulent and offensive A bacteriologic examination showed the presence of gonococci in the discharge There were occasional small uterine hemorrhages

Operation—March 10, 1898 A thorough curettement of the uterus was done with a sharp curette and the cavity packed with iodoform gauze Two days later the packing was removed and the uterine cavity was irrigated with an antiseptic solution The os and cervical canal were patulous, the uterine cavity dilated, and the walls of the uterus very elastic, so that we felt the necessity of caution in curetting, lest the uterine wall be punctured or torn

After History—For a few weeks after the curettage the pa

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION —Illustration of article by Dr L H Dunning tient was markedly better, but then the discharge gradually increased, became offensive and irritating, and slight hemorrhage appeared The patient declined to have anything further done for two years, when the suffering became intolerable, and I was asked to do another curettage I advised a hysterectomy, but it was rejected, so, Jan 6, 1900, another thorough curettage was done As in the former instance, this brought relief for a time, when again the discharge became profuse, offensive in odor and irritating to all the tissues it touched In January, 1904, the husband of the patient consulted me about his wife's case He said she was well nourished and able to attend to her household duties, but that she had the same old foul, irritating discharge, and occasional hemorrhages I urged the advisability of a hysterectomy, but this the patient declined, and I lost sight of the case

Case 1 illustrates the further extension of the inflammation into the uterine appendages and pelvic peritoneum In this instance, however, there was a mixed infection Investigations have not extended far enough to justify positive statements regarding the relative importance of the different pathogenic bacteria It is highly probable however, that the same principles and facts apply in senile endometritis that do in ordinary anteclimacteric endometritis

SYMPTOMS AND COURSE

Senile endometritis is not a self-limited disease It is prone to persist for a long period of time The acute form after a time gradually merges into the chronic form The symptoms are alike in both the acute and chronic forms, varying only in intensity

Some time in the course of chronic senile endometritis there is likely to appear inflammatory changes in the mucous membrane of the vaginal and urinary tracts, and also in the mucous membrane of the rectum When these complications arise, the patient suffers much distress on account of offensive discharges, frequent and painful micturition, and an uncomfortable fullness and painful feeling about the rectum Vulvitis is common, and leads to intense itching and marked nervous symptoms The most prominent symptom due to senile endometritis is the discharge from the uterus This discharge is purulent, muco-purulent or sanguinopurulent. Ofttimes it is of exceedingly offensive odor and in not a few cases the hemorrhage is considerable, but the sanguineous discharge is most frequently mixed with purulent material, and more or less of the composite mixture may be retained in the uterus and become exceedingly offensive In two of my cases I was entirely unable at first to understand why so much of this material accumulated within the uterus The os was patulous in both cases On examination the uterus was found to be slightly retroverted The walls of the uterus were thin and elastic and a histologic examination showed the muscular walls to be weakened by degenerative processes In these instances we had a full explanation of the cause of the retention, in the retroversion and in the diminished contractile power of the uterus

Dr Ferguson suggests that in cases such as he and Dr Ritter examined, inasmuch as the discharge found in the uterus on opening it after the operation was slight and inoffensive, that it is probable that the uterine discharges were arrested in the folds of the vaginal mucous membrane and there came in contact with bacteria which induced decomposition and gave rise to the offensive odor so pronounced on vaginal examination

Occasionally the internal os is closed This, however in my experience is not frequent and in this my observations are at variance with those of some writers In the few cases in which I have found retained pus, blood and débris in the uterine cavity the odor of these fluids has been exceedingly offensive.

Usually the cervical canal is easily dilatable, so that a large-sized sound may be passed with ease The purulent discharge is usually creamy in consistency, sometimes of an offensive odor, and more or less irritating to the external genital organs

Pain is a persistent symptom The pain is burning in character Occasionally the patient may describe the pain as a sore pain, and in rare instances the soreness of the pelvic organs is the chief cause of complaint Many patients complain of backache and languor, and not a few of them are cachectic, the cachexia being due to a mild form of sepsis In the acute cases there are also systemic disturbances, such as a low grade of fever and general malaise Ofttimes the symptoms produced by the incidental or complicating lesions will overshadow the symptoms produced by the endometritis This is true especially if there be vulvitis attended by soreness, pain, itching and extreme nervousness, or if there be kraurosis of the vulva and a caruncle of the urethra Probably cystitis is the most distressing complication

In a former article[1] I gave the results of a microscopic examination of a uterus in which the lesion was acute senile endometritis To-day I present the histologic findings in two cases of chronic endometritis The first case is as follows

Case 3 —Mrs C, aged 63 years, was referred to me Jan 27 1904, by Dr Peacock of Ladoga, Ind The patient passed the menopause twenty three years ago She states that her health was good until four or five years ago, when she had an attack which was pronounced gallstone colic She recovered from this when she began to have falling of the womb The latter disease was gradually increased until it had become a great source of discomfort to her, and has been aggravated because of the necessity of her being compelled to lift and care for a helpless husband She says that for about a year she has had a creamy discharge from the genitals Last August, five months ago, she had the first bloody discharge Since that time she has had a bloody discharge almost continuously This discharge was at times quite profuse She states that there is at times a watery discharge, the odor of which is very offensive.

Examination —The uterus was prolapsed to the second degree, the vaginal walls partially prolapsed, thickened and reddened The external os showed some slight redness with two or three small areas of papillary enlargement. These bleed readily on touch There did not seem to be any localized area of inflammation or irritation of the vaginal walls The prolapsed portion of the vaginal walls showed the usual thickening and roughening, due to prolapsus, and irritation due to the friction of the patient's clothing The depth of the uterus was 2½ inches Quite a little sanguino purulent discharge passed from the uterus on examination It had an offensive odor

Diagnosis —I made a diagnosis of senile endometritis and prolapsus of the uterus, and decided to extirpate the uterus because of the prolapsus, which had not been relieved, notwithstanding a prolonged and persistent effort by her regular physician

Operation —The patient was sent to St. Vincent's Hospital and was operated on Feb 3, 1904 in the presence of the medical students, internes and with the assistance of Drs J Q Davis and C E Ferguson A hysterectomy was done by the Clamp method The uterus and appendages were handed over to Dr Ferguson for bacteriologic and histologic examination His report is herewith appended, together with drawings (Figs 1 and 2, Case 3) from microscopic sections

Dr Ferguson reports on this case as follows

Pathologic Report —"The length of the uterus is 3 inches a little more than one-half of which is cervix The depth of the canal is 2½ inches and patulous throughout its course The anterior and posterior walls of the body are each ¾ of an inch in thickness and very firm and resistant to the knife A cyst the size of a pea is seen on the cervical mucosa at the internal os The anterior and posterior lips are much thickened The endometrium from the internal os to the fundus is ecchymotic and closely studded with minute elevations

Microscopic Report—"Material obtained from a portion of the mucosa by gentle scraping shows an almost entire absence of columnar epithelia, and the presence of a large number of squamous epithelia, and a few red blood cells are found Sections show the surface epithelium changed or absent Extensive round celled infiltration of the mucosa is found, that in many places extends into the muscularis Glands are numerous, extend into the muscular layer, but are *not* tortuous as in endometritis glandularis chronica The mucosa presents numerous cystic spaces, in some instances filled with blood These spaces are dilated glands, lined by a single layer of columnar epithelium The capillaries are numerous in some parts of the mucosa, dilated and filled with blood The mucosa is thickened and infiltrated with blood throughout a greater part of its depth and surface The blood vessels of the uterine wall show marked arteriosclerosis, the thickened walls in some instances almost entirely closing the lumen This thickening is confined to the intima

The cervix shows marked increase in the glandular elements, numerous cyst adenomata, and congested blood vessels are present Arteriosclerosis is marked Round celled infiltration extends for some distance into the muscular layer

"Altogether, the microscopic examination gives the picture of a well-marked chronic endometritis in a senile uterus, with a tendency to hemorrhage, the hemorrhage being due to circulatory disturbances, probably dependent on degenerative changes in the walls of the blood vessels and chronic congestion incident to prolapsus of the uterus

Bacteriologic Report—"Immediately after the operation the uterus was bisected and cultures made from the endometrium on blood serum, agar agar and gelatin The result in every instance was negative A similar bacteriologic examination was made in Case 4, with a negative result"

CASE 4—Mrs D, aged 61 years, consulted me April 4, 1904, on account of prolapsus of the uterus which had existed 1½ years and had been treated by posture, tampons, pessary, etc, without more than temporary relief She was a well nourished and active woman On examination of the heart, lungs and kidneys nothing abnormal was found She complained of weight and burning pain through the uterus, and stated that she had a thin, creamy discharge from the uterus, which was irritating and at times of offensive odor She passed the menopause eleven years ago, and was not aware of the presence of any uterine disease or displacement until 1½ years ago The displacement of the uterus preceded the appearance of the discharge several months Two weeks ago she had, for the first time in eleven years, a sanguineous flow from the uterus lasting four days and as abundant as an ordinary menstruation

Examination—I found the uterus protruding from the vagina There was also prolapsus of the vagina, and the os was larger than normal, but not eroded The uterine sound passed readily into the cervical and uterine canals 2¾ inches

Operation—She was sent to the Deaconess Hospital and operated on April 6, 1904 The external os was closed by sutures, and the uterus extirpated by the clamp method

Pathologic Report—An examination of the uterus after removal showed the organ rather larger than the normal senile uterus There was supravaginal elongation of the cervix The cervical canal was patulous and the uterine cavity easily distensible There was no evidence on macroscopic examination of hemorrhage beneath the mucous membrane or into the muscularis

The specimen was given to Dr R H Ritter for critical examination Dr Ritter's report was as follows

"The uterine cavity was opened after the surface had been seared by a sterile knife, and the surface of the mucosa gently scraped by the platinum loop Culture tubes of gelatin, agar and blood serum were inoculated

"The uterine cavity is small, the mucosa lining it smooth, even and glistening The cervical canal is pervious There is a rather more than normal constriction at the internal os, but the external os is gaping There are numerous small colored spots, about the size of large pinheads, resembling petechiæ scattered throughout the corporeal mucosa

Microscopic Report—"Sections were made from six areas of the mucosa All present the same picture The mucous membrane varies greatly in thickness In some places it is thin and contains very few glands The glands that remain are small, usually with a very narrow lumina, and lie more or less parallel with the surface There is no inflammatory infiltration These areas then, exhibit the normal atrophic changes of senility

"In other regions the endometrium is of normal or perhaps slightly increased thickness, the glands are numerous but irregular and tortuous, many having dilated lumina The stroma of the mucosa in such places is quite dense, especially around the glands There is an irregular round celled infiltration of inflammation in these areas Throughout the whole endometrial surface the epithelium is almost entirely gone Only a few patches are seen, most of them lying about the mouths of glands The epithelial cells are very much flattened and are described as cuboidal, or even squamous, cells

There is no evidence of an ulceration of the mucosa, and no loss of substance by necrosis and sloughing to produce the 'thin' areas There has apparently been a simple epithelial degeneration I can find no evidence of hemorrhage into the mucosa or into the glands, nor any pathologic changes in the capillaries The muscularis shows a spread of fibrosis, probably not more, however, than is normal to the senile organ The blood vessels are markedly thickened, the lumen in many cases being almost obliterated by the thickened intima Hyaline degeneration has taken place to a marked degree in these vessels Throughout the larger bands of connective tissue, and involving also bands of muscle fibers, are masses of mucoid tissue, evidently a secondary change to the fibrosis"

There is a marked similarity in the macroscopic and microscopic appearances of these two uteri The evidences of inflammation are almost identical in both and this leads me to believe that they may be taken as the type of many cases of chronic senile endometritis, in which an anteclimacteric endometritis is prolonged and continued as a lesion after the menopause

The characteristic inflammatory lesions present are a thickened mucosa, for the most part divested of epithelium, and showing round-celled infiltration marked granular activity, the glands in both cases being here and there dilated and in some instances cystic The inflammatory process showed greater activity in the region of the glands The glands are lined with columnar epithelium, while the epithelium on the surface of the mucosa is flattened There is a tortuous course of the glands, and in one case (Fig 1 C) the lumina of a few of the glands are filled with blood The round-celled infiltration extends into the muscularis In this tissue, in Case 4 (Figs 5 and 6) was found mucoid degeneration of the connective and muscular tissue In both cases there is marked arteriosclerosis, and in one also hyaline degeneration of the walls of some of the arteries

In both cases there was considerable hemorrhage In one case (Fig 1) there was found effused blood in the endometrium and in some of the glands In the other case there had been but a single hemorrhage (profuse) yet there was more evidence of degeneration in the walls of the blood vessels than in Case 3 It is probable that had not the uterus been removed subsequent hemorrhage would have occurred

DIAGNOSIS

The diagnosis is made by the symptoms above enumerated and by the physical signs The pain and soreness in uncomplicated cases are distinctly referred to the uterus As a rule, the upper portion of the vagina is inelastic and the uterus difficult of palpation The vaginal portion of the cervix may be almost entirely obliterated, but the patulous external os can usually be felt In such cases it is common to find the vaginal mucous membrane surrounding the os more or less eroded in small areas, and the whole circumference of the upper portion of the vagina infiltrated and inelastic If now in this field is seen the opening of the patulous os, from which exudes a mucopurulent or sanguinopurulent discharge, we have in all probabilities to deal with a case of senile endometritis and if, further, a sound passes readily into the uterus, and by it it is determined that there is an absence of any neoplasm, and there is the presence of a smooth mucous surface lining a dilated cavity of the uterus, the diagnosis of senile endometritis may be confidently made

In other cases, especially if there be prolapsus of the uterus or laceration of the cervix, the cervix may be unusually large for a post-climacteric uterus Cystic degeneration of the cervix may be observed or an angry erosion which bleeds readily on the slightest touch Occasionally there will be found slight papillary elevations projecting from the eroded surface This latter appearance closely resembles that seen in incipient squamous-celled epithelioma of the cervix, and a differential diagnosis can be positively made only by a histologic study of portions of the diseased tissues removed for examination Another source of difficulty in diagnosis is an occasional presence of an adenoma of the cervix In these cases the sanguineous flow is more abundant and the discharge less purulent Here also a histologic study of portions of the diseased areas must be made to confirm the diagnosis

The same remarks hold true regarding the diagnosis in doubtful cases in which there is a sanguineous discharge from the interior of the uterus Here it is wise to thoroughly curette the uterus and make search for evidences of malignancy in the scrapings In all the cases of suspected senile endometritis in which I have explored the interior of the uterus with a dull curette, and there has been an absence of anything resembling a neoplasm, the case has proved to be non-malignant In the case of a sloughing submucous fibroid tumor the difficulties of diagnosis with microscopic examination are insurmountable In severe persistent cases I think it important to determine the character of the infection, as those due to mixed infection will likely require energetic treatment while cases dependent on gonorrheal infection will often demand hysterectomy When the internal os is closed the uterus will be found distended, so that if a probe be carried through the obstruction and the opening thus made dilated, there will be an escape of a considerable quantity of purulent or sanguinopurulent bad smelling discharge

TREATMENT OF SENILE ENDOMETRITIS

At the beginning of acute cases it is all important that good drainage be established and the complications duly treated Should there be stenosis of the os it should be overcome by gentle yet thorough dilatation The steel dilator may be used, but the tissues of the cervix are so inelastic that forcible dilatation must be employed with gentleness lest the tissues be lacerated The slippery-elm tent when it can be passed through the internal os is quite efficient In the acute cases I do not believe the curette should be employed until the intensity of the symptoms has passed I have on several occasions after dilating and washing out the cavity, made applications to the interior of the uterus of pure carbolic acid, and followed this in one to one and one-half minutes with an injection into the cavity of commercial alcohol No outward symptoms have followed this procedure, and very marked relief of the soreness and discharge has resulted This is, I believe, appropriate treatment for both the acute and chronic cases Such applications for a few times may be repeated once a week if well borne When the acute symptoms have passed, dilatation, curettage and packing with iodoform gauze have been beneficial and not infrequently curative The advantages gained by the curettage should be followed up by maintaining a patulous condition of the os and by making applications to the endometrium of solutions of nitrate of silver in strengths of 5 to 10 grains per ounce

Reference to Figure 6, Case 4, together with Dr Ritter's description of the microscopic findings in this case, will, I think, afford an explanation of the fact that not infrequently a curettage fails to effect the cure of endometritis In this case the inflamed portions of the mucosa were found in islands or patches, while other portions of the mucosa were normal If a curettage is not sufficiently thorough to remove the mucosa in every part of the uterine cavity and cervical canal, that part untouched by the curette or only partially removed, if inflamed may remain as a focus, from which will spread the lesion after regeneration of the endometrium

If senile vaginitis and vulvitis exist with the endometritis, these conditions should be, if possible, cured before the curettage

To this end, two or three times a week the vulva and vagina may be painted with a solution of silver nitrate This, with the applications twice a day of Lassar's paste to the inflamed tissues and the use of astringent and antiseptic douches, usually bring relief

In those cases dependent on the presence of a necrotic fibroid tumor, the remnants of the neoplasms should be removed by the curette or other means The writer has met with little success in overcoming retroversion of the senile uterus If this displacement is the cause of the endometritis, and the ordinary means of cure fail in the grave cases, recourse may be had to hysterectomy

During the progress of the local treatment attention should be given to the general health of the patient Tonics, alteratives and laxatives may be employed according to the requirements of the case[2] Skene places much reliance on the local effects of iodoform applied as a powder to the endometrium

The tendency toward recovery in senile endometritis is not marked, indeed, the disease is prone to persist in spite of all treatment When it does persist and contributes largely toward the production of the ill health of the patient, vaginal hysterectomy may be resorted to if the patient's condition demands and will justify such a procedure

In all, I have extirpated the uterus in cases of senile endometritis six times—five times by the vaginal route and once by the supravaginal route In two cases the endometritis was associated with procidentia, which furnished the chief indication for hysterectomy, in one case there was chronic sepsis, due to absorption from the uterus, in one case the appendages had been extirpated because of gonorrheal salpingitis and the endometritis was distressing and incurable, the patient being an invalid In the remaining case the uterus was extirpated under a mistaken diagnosis, as I believed I was dealing with a case of cervical cancer These were aggravated cases of senile endometritis with grave complications, and the results of the hysterectomy were most gratifying

---

[2] Medical Gynecology p 500

In those cases in which there is atresia of the os and a resultant pyometra, great care must be exercised in effecting an entrance into the uterine cavity and in maintaining a patulous os A medium-sized, blunt-pointed probe may be gently insinuated into the os, pushed into the cavity, and this followed by one of larger size, and a still larger one until an opening of sufficient caliber has been made to admit the passage of an elm tent The dilatation of the os should be ample After a few days of draining of the cavity, curettage or the treatment of the interior of the uterine cavity with the carbolic acid and alcohol may be resorted to

When suppuration of the fallopian tubes or ovaries appear in the acute cases, hysterectomy and salpingo-oophorectomy is in my judgment the proper procedure

ARTERIOSCLEROSIS DUE TO LEAD*

FRANK S BILLINGS, M D
CHICAGO

The subject assigned to me in the symposium was Arteriosclerosis Due to Metallic Poisons"

I have had no experience with the effects of other metals, and, therefore, confine my remarks to the toxic influence of lead

MODE OF ENTRANCE TO THE SYSTEM

Lead and its compounds are so commonly used by man that it is not surprising to meet with its toxic effects in the body This occurs more frequently because with some individuals it gains easy access to the body

Not only may it be taken into the body as a contamination of food and drink and doubtless from prolonged medicinal use, but it may also be taken into the alimentary tract from the hands soiled with metallic lead or from lead paints Doubtless it may be absorbed through the skin, as frequent cases of poisoning have occurred from the use of lead hair dyes

Cigarmakers sometime roll cigars on tinned plates which contain lead, and susceptible individuals are poisoned Diamond cutters who imbed gems in an amalgam of lead, which can be molded in the fingers and facilitate the cutting of the stones may suffer from lead poisoning

There can be no question that some individuals are very susceptible to lead

There is now in the Cook County Hospital, Chicago a man who is suffering from lead intoxication, who came in contact with the metal in the following way Once a week, in his bare arms, he carried the bars of lead solder, used to seal the locks of freight cars to the several cars of a train This brought his skin in contact with lead for a few minutes only once a week

Within the last few weeks I have also seen a woman who showed a typical blue line on the gums, granular degeneration of the red blood cells, and complained of marked colic and constipation

She washed the paint-smeared clothes of her husband, a house painter I could not learn that she came in contact with lead in any other manner

BLOOD CHANGES IN LEAD POISONING

When lead intoxication produces the typical blue line on the gums, the intestinal colic and constipation, the anemia, the palsies and encephalopathy, we recognize it readily

There can be no question that it also produces latent toxic effects which are not as easily recognized

The interesting observations of Moritz,[1] White and Wilcox,[2] Grawitz,[3] Homel,[4] Schur and Lowe,[5] Rosin and Bibergeil,[6] Reitter[7] and others, of the presence of red blood cells showing granulations in persons suffering with lead poisoning are important

With few exceptions, all observers agree to the constancy of the granulation of the cells of the blood in lead poisoning Many workers in lead, who present no other symptoms show this blood change

The blood of animals fed on lead early exhibits the granules in the blood cells Most observers look on the granules as of protoplasmic origin and degenerative in character The granules disappear from the blood when the cause is removed

Some individuals are more susceptible to this so-called basophilic granulation than others, and workers in lead whose place of occupation is less sunny and poorly ventilated suffer more than those in better hygienic surroundings Basophilic granulation is by most observers considered of value in diagnosis, and the disappearance of the granules is a good prognostic sign

EFFECT OF LEAD ON OTHER TISSUES

There is abundant experimental and postmortem evidence that lead may attack practically all the tissues of the body

Annino[8] fed lead to dogs, rabbits, rats and mice, and found that animals even of the same litter differ much in resistance Lead soon appeared in the urine Lead was also found in the fetus, which explains the tendency of women who suffer from lead poisoning to abort

In the different tissues it was noted that the lead produced varied effects

In protoplasm, cloudy swelling, fatty degeneration, vacuolization and granular atrophy and hyaline degeneration of the nuclei

In the later stages, connective tissue hyperplasia There was a decided tendency to hemorrhage and endarteritis, even to obliteration He observed fatty degeneration of the muscularis and of the capillary endothelium

Coene and D'Ajutolo[9] found that lead had first, a destructive action on parenchymatous tissues second, on the blood and blood vessels, and, finally, a sclerosing action This effect, they claimed, applied to all organs, but was most pronounced in the kidney

Oeller,[10] in an article entitled "Ueber hyaline Gefassdegeneration als Ursache einer Amblyopia Saturnina," found in the vessels of the eye endarteritis, hyaline degeneration, thrombosis and hemorrhage He argued that similar changes occurred in the vessels of other organs, notably the kidney, in lead poisoning

[9] Ziegler's Beiträge 1898, vol iii p 449
[10] Virch Arch, 1881, vol lxxxvi p 329

Stieglitz[11] found similar changes in the blood vessels, but most marked in the pulmonary circuit Mairer found the larger arteries unchanged, but very characteristic lesions in the smaller vessels He described aneurismal dilatations chiefly in the vessels of the intestinal tract, and other observers have found the same changes in the vessels of the kidneys, the muscles, the nervous system, the liver, etc Other observers confirm the findings of Stieglitz in reference to the involvement of the pulmonary vessels The changes consisted of endarteritis, fibrous thickening of the intima, hyperplasia of the periarterial connective tissue, excess of nuclei and thickening of the media The heart muscles showed fatty degeneration

Charcot and Gombault[12] produced changes in the kidneys of animals very similar to the chronic interstitial nephritis associated with lead poisoning in man

Coen and D'Ajutolo,[9] in their experiments on rabbits found that lead produced in the kidney parenchymatous degeneration, glomerulitis, with hyaline degeneration of the blood vessels and finally interstitial nephritis In the stomach, proliferation and degeneration of the cells of the glands, localized inflammatory changes in the arteries with endarteritis and perivasculitis in the submucosa Similar changes in the vessels of the intestine, liver and muscles The general sequence of changes noted by them were parenchymatous degeneration, blood-vessel changes, interstitial hyperplasias

Prevost and Binet[13] made extensive experiments of the effects of lead on rats, rabbits and guinea-pigs Nephritis could always be demonstrated microscopically

The experimental evidence of the toxic effect of lead on the various tissues of the body is supported by numerous postmortem records

Dickinson[14] reports that of 42 workmen having labor which exposed them to lead poisoning, dying from disease or accident in St George's Hospital, 26 had granular degeneration of the kidneys, with the usual cardiovascular changes Again, of 45 men dying of granular degeneration of the kidneys, 10 were lead workers

Leyden[15] relates a case with severe and widespread symptoms of lead poisoning

The autopsy showed the typical granular kidney The glomeruli were shrunken and fibrous, the afferent and efferent vessels and the tufts showed hyaline degeneration, moderate hypertrophy of the intima in some of the large vessels The left heart hypertrophy and a full, sustained, radial pulse during life Three other similar cases were reported with like findings

Leyden calls attention to the fact that there is practically no general arteriosclerosis in these cases of nephritis due to lead poisoning The arteries of the kidney are thickened by hypertrophy of the muscular coat,

Kussmaul and Maier[16] give the pathologic anatomy of chronic saturnismus This case they studied during life and postmortem. Clinically, there was a typical chronic plumbism, with nervous symptoms, colic, etc

Histologically, the connective tissue of the submucosa of the intestinal tract showed hyperplasia The walls of the vessels were decidedly thickened, especially the adventitia of the arterial twigs, with narrowing of the lumen There was a marked tendency to fatty degeneration of the muscular and glandular elements with decided atrophy There was a slight and definite increase of the connective tissue surrounding the blood vessels of the spinal cord, brain and the sympathetic ganglia

Von Schrotter[17] quotes a personal communication of Kolisko, who has made extensive observations of the arteries under the influence of lead Kolisko says that the vessel changes consist chiefly of hypertrophy of the media Preceding degenerative changes, as are usual in sclerosis, were not observed, and the intima is only occasionally the seat of hyperplasia.

Senator,[18] in the discussion of the relation of lead to chronic interstitial nephritis and the associated cardio-vascular changes, gives Lancereaux[19] the credit of first recognizing the importance of lead as a causative factor in nephritis Ollivier[20] also recognized the importance of lead as a cause of nephritis Senator also cites the experiments and conclusions, already quoted of Charcot and Gombault, Coen and D'Ajutolo, and the clinical and postmortem observations of Dickinson In addition, he quotes Jacob,[21] who found 12 cases of granular kidney, of whom 8 were lead workers Wagner[22] found lead as the cause fifteen times in 150 cases Senator was able to verify lead as a cause of the nephritis in 10 of 180 cases, and in 6 of these cases the clinical data were verified by autopsy

Thomas Oliver[23] discusses lead intoxication, and believes the sclerotic changes of the kidney are secondary to an original degeneration of the epithelium of the tubules The glomeruli finally become involved in the degenerative changes, and sclerosis ultimately occurs

Gombault[24] says that lead poisoning, like alcohol, syphilis and gout, has an injurious effect on vessel wall nutrition, hence predisposes to degeneration and sclerosis

Ebstein[25] discusses the relation of lead to gout In 1,103 cases of lead poisoning, gout occurred in 103 He cites other observers giving the same result In individuals predisposed to gout, even small doses of lead may cause an attack of gout

He believes that an hereditary predisposition to gout must exist in order that lead may cause gouty symptoms

Oliver[26] says that on experimental and pathologic grounds lead has a direct harmful influence on the kidney The first changes are parenchymatous, the second interstitial, that is, cloudy swelling and fatty degeneration in the convoluted tubules At the same time there occurs cellular proliferation in the labyrinth about the afferent glomerular vessels, on the inner Bowman's capsule, and between the tubules Then develops a true interstitial nephritis, with thickening of the walls of the vessels, described by Oliver as a mixed nephritis

Von Jacksch[27] says that in lead intoxication there are always serious changes in the nitrogenous metabolism of the body, resulting in an increased production of uric acid According to the newer theories of uric-acid formation, it must be supposed that under the influence of lead, there results an excessive destruction of nuclein containing substances This toxic influence is according to von Jacksch, a decreased oxidation

CONCLUSIONS

From the above opinions of the effect of lead on the blood vessels and on those organs which, when diseased, have an associated or resultant thickening of the walls of the vessels, we may conclude that lead may produce a disease of the blood vessels either directly or indirectly

Directly, as shown by the numerous experiments on animals Probably this is by the direct influence on the vessel of the lead in the circulating blood Doubtless the walls of some of the larger arteries may be affected through the alteration in the nutrition, because of the primary toxic endarteritis, with the tendency to thrombosis and obliteration of the vasa vasora

The undisputed fact that lead may cause gout, and the equally true proposition that in gouty individuals arteriosclerosis occurs early, may explain the influence of lead in producing arteriosclerosis in rare cases

Experimental and clinical observations prove incontestably that lead will cause nephritis This is usually the contracted kidney, which sooner or later has associated with it the thickened arteries and left cardiac hypertrophy

Lead intoxication may lead directly and indirectly to arteriosclerosis

The recognition of lead intoxication during life, by any of the ordinary symptoms or by the basophilic granulations of the cells of the blood, in an individual suffering with arteriosclerosis, with or without nephritis, would not, perhaps, permit us to say definitely that the lead was the sole causative disease factor It would, however, be a rational therapeutic measure to safeguard the individual against further intoxication with lead in the treatment of the arteriosclerosis

100 State Street

THE RELATION OF ALCOHOL TO ARTERIOSCLEROSIS *

RICHARD C CABOT, M D

BOSTON

LITERATURE

Most standard text-books[1] assert unconditionally the importance of the excessive use of alcoholic liquors in the production of arteriosclerosis Standard treatises on the heart and blood vessels[2] are equally emphatic In Nothnagel's magnificent "Specielle Pathologie und Therapie," Schrotter says, after reviewing the literature "Alcohol is considered by practically all writers on arteriosclerosis as the chief cause or at least one of the most important causes of the condition " Yet Schrotter himself seems to be somewhat dubious regarding the evidence on which the belief is founded, and there are others, such as Duclos[3] and Ribberts,[4] who are yet more outspoken in their skepticism

CLINICAL RESEARCH

1 I investigated first the question

How many cases of arteriosclerosis not referable to syphilis or to advancing age are to be found among alcoholics?

At the Bridgewater State Farm and the Foxboro Asylum for Dipsomaniacs, I investigated 283 cases of the severest and most chronic forms of alcoholism, excluding those over 50 years of age and those who have had syphilis A quart of whiskey daily for many years was a not infrequent history in these cases[5]

Of the total 283 cases, only 18, or 6 per cent, showed arteriosclerosis, so far as could be ascertained by examination of the heart and peripheral vessels, and by questions regarding the functions of the kidney[6] If the cases over 40 years be excluded also, the percentage showing arteriosclerosis falls to 1 4 per cent

2 I next endeavored to determine in what proportion of cases of relatively early arteriosclerosis of the peripheral arteries alcoholism was present

Out of the several hundred cases of arteriosclerosis seen by me at the Massachusetts General Hospital, 45 were under 50 years of age Only 6 of these, or 13 per cent gave any history of alcoholism

POSTMORTEM EVIDENCE

3 By the kindness of Dr J H Wright of the Massachusetts General Hospital clinicopathological laboratory, and of Dr F B Mallory, pathologist to the Boston City Hospital, I was enabled to examine the records of 656 patients, 95 of whom were under 50 years of age and with no history of syphilis, in which arteriosclerosis formed a part of the pathologic diagnosis at the autopsy On looking up the clinical records of these 95 cases, it was found that in 57 cases, or 60 per cent, it is expressly stated that the patient took no alcohol Regarding the remaining 39 cases, in the table given below, I have quoted the actual words of the record It will be seen that in 8 cases excessive alcoholism is expressly stated to have been present In 14 cases it is stated or implied that the amount of alcohol consumed was moderate, while in 5 cases the statement may be interpreted as an insignificant amount of alcohol Subtracting these 19 cases we have left 20 or 21 per cent, in which the consumption of alcohol was excessive

It will be seen from the table that 8 of the cases among those who took more or less alcohol, were found at the autopsy to have chronic nephritis as well as arteriosclerosis, so that if, as is usually believed chronic nephritis is a cause of arteriosclerosis, these cases should be subtracted from those which might be supposed to be due to alcoholic excess This would remove 4 of the cases in whose clinical record excessive alcoholism played a feature

It should also be borne in mind that as most of these cases were taken from the records of the Boston City Hospital, and as that hospital is patronized very largely by those in whose history alcoholism is a feature, the possibility of a coincidence in the occurrence of alcoholism and arteriosclerosis can not be disregarded

Finally, I will mention briefly the case of a well-known young Bostonian, who deliberately drank himself to death at the age of 36 For the previous ten years

---

*Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Practice of Medicine and approved for publication by the Executive Committee Drs J M Anders, Frank Jones and W S Thayer

[3] Duclos Du Systeme arteriel chez les alcooliques Paris, 1888

[4] Ribbert Pathol Anatomie 1902, p 612

[5] I desire expressly to thank Dr Charles A Drew Medical Director of the Bridgewater State Farm, for his assistance in securing data on these cases

[6] Patients whose arteries were merely palpable without being tortuous hard or rough were not counted as cases of arteriosclerosis

of his life he had been in the habit of taking one or two quarts of whiskey a day for about eight months in the year At the postmortem examination particular attention was paid to the condition of the arteries and they were found to be entirely normal

CONCLUSIONS

1 Only 6 per cent of 283 cases of chronic and excessive alcoholism under 50 years of age showed any evidence of arteriosclerosis

2 Of 45 cases of arteriosclerosis examined by me at the Massachusetts General Hospital, only 13 per cent gave any history of alcoholism

3 Of 656 autopsy cases of arteriosclerosis only 95, or 14 5 per cent, were under the age of 50

4 Out of these 95 cases under 50, in which arteriosclerosis was found postmortem, only 21 per cent, and if we exclude cases complicated by chronic nephritis only 17 per cent appear to have consumed alcohol in any notable excess

The details of the autopsied cases may be seen from the following table

TABLE OF POSTMORTEM AND CLINICAL RECORDS IN CASES OF ARTERIOSCLEROSIS

Case	Age in Years	Pathologist's Diagnosis	Previous Diseases and Present Complications	Amount of Alcohol Consumed
1	30	Art.	Ch nephritis	Five or six whiskies daily for last 15 years.
2	36	Art		One or two wines daily never to excess
3	41	Art	Phthisis	Moderate alcohol.
4	24	Sl. art.	Ch nephritis.	Alcohol moderate
5	43	Sl scl. of aorta		Always hard drinker
6	37	Art	Phthisis.	Four or five whiskies and four or five beers daily
7	21	Sl scl. of aorta	Typhoid fever	Alcohol in moderation, but regularly
8	35	Gen art	Ch nephritis.	Four or five whiskies before breakfast
9	21	Sl art	Typhoid fever	One whisky every other day
10	38	Sl. art	Diphtheria, ch nephritis.	Four to six beers daily occasionally whisky
11	31	Sl. art		Two or three whiskies and four or five ales daily
12	32	Art		'Drinks considerably '
13	43	Sl art		Alcohol excessive
14	30	Art of aorta		Two glasses of whisky a week and two beers daily
15	43	Art aorta		Beer and whisky occasionally
16	39	Art	Typhoid fever	Half pint whisky daily
17	39	Art	Typhoid fever	Occasionally whisky
18	40	Art		Alcohol to excess
19	44	Ar	Ch. nephritis	Drank heavily of beer
2	46	Art of aorta		Alcohol to excess
21	34	Art		Alcohol to excess.
22	46	Art.		Two or three whiskies and two beers daily
23	46	Art.	Aortic regurg	Alcohol moderate, but steadily for years.
24	25	Sl. art.		Alcohol in excess.
25	33	Scl mitral curtain and aortic arch		Alcohol in great excess
26	37	Aortic scl		Alcohol for last 10 years
27	24	Coronary scl	Ch nephritis scarlet fever	Three or four beers daily occasionally whisky
28	42	Aortic scl	Ch nephritis	Alcohol to excess
29	43	Gen. art	Phthisis.	Four or five beers daily
30	48	Gen art	Ch nephritis	Alcohol considerable
31	38	Gen art	Fatty deg heart	Diag alcoholism (acute) Amt of alcohol not known
32	20	Art	Typhoid fever	Takes less than one drink a day (beer)
33	44	Gen. art	Ch. nephritis	Occasional glass of ale, gin or whisky
34	29	Gen art	Aortic insuf	Four beers daily
35	41	Art		Rum three glasses week, year around
36	42	Art		Two or three bottles of ale a day
37	39	Art.	Typhoid fever	Drank lots of beer till year ago—four or five glasses a day—and 'a certain amount of whisky "
38	40			No alcohol for last 13 years before then 14 or 15 whiskies a week
39	41	Art.	Smallpox	Two or three beers daily half pint of whisky a week, off and on

In Cases 40 to 95 the record expressly states that the patient did not use alcohol

Art.—Arteriosclerosis ch.—chronic sl—slight gen—general scl—sclerosis deg—degeneration

ANGINA PECTORIS AND ARTERIOSCLEROSIS *

WILLIAM OSLER, M D

BALTIMORE

In contrast to the many uncertainties relating to angina pectoris is the circumstance that in a large proportion of cases the attack is only an incident in the history of arteriosclerosis Since Edward Jenner demonstrated postmortem disease of the coronary arteries the association of a lesion of these vessels with the disease has been accepted as one of the best attested facts in cardiac pathology Not that it has helped much to explain the mysterious nature of the pain of the attack, or all of the phenomena of the paroxysm Pain in arteriosclerosis, as we see it in other parts, deserves a more careful study than it has yet received In the head there is the association of migraine with arterial disease, the severe and characteristic headaches of arteriosclerosis and high pressure, and the agonizing pain in some cases of embolism of the cerebral arteries, more rarely in thrombosis Abdominal pain is not often due to vascular disease, though there are cases in which from the situation and intensity of the paroxysm it might rather be called angina abdominis than pectoris There may be severe pain in lesions of the mesenteric arteries and in thrombosis of the iliac vessels in typhoid fever It is in sclerosis of the arteries of the extremities that we meet with the most remarkable disturbances of sensation The pain in embolism or thrombosis of the femoral or popliteal arteries is very intense, particularly at the site of the lesion In the ordinary sclerosis, particularly of elderly persons, there may be, first, simple paresthesiæ, the numbness and tingling so commonly complained of, secondly, attacks of painful cramps, usually slight and nocturnal, or recurring paroxysms of extraordinary intensity and deserving the name of angina cruris more than intermittent claudication, which Walton has applied to it, thirdly, the pain, not always present, in intermittent claudication fourthly, the paroxysms of pain with erythema, etc the arteriosclerotic type of erythromelalgia

But the pain in angina pectoris is *sui generis,* unlike in intensity any known variety, and while its association with coronary artery sclerosis is unquestionable there is something additional, some other element for which, as yet, we have no explanation

In relation to arteriosclerosis, there are four groups of cases of angina pectoris First, the neurotic, in which in young persons all the symptoms of the disease may be present and death occur, and autopsy shows normal coronary arteries and neither local nor general disease of the arteries Such cases are not common, but I have reported an instance in a young man of 28 who had had for years paroxysms of cardiac pain of the most agonizing form, who died in an attack

Secondly, the angina pectoris of young men associated with syphilitic arteritis, aortic or coronary, or both This is a very distinctive form, occurring usually in men under 35 years of age There may be no general arteriosclerosis, but the lesion is either at the root of the aorta, or involves the sigmoid valves, or it may be confined to the coronary arteries The anginal attacks, while severe, are sometimes relieved or even cured by the iodids The paroxysms of pain may be the initial symptoms of aneurism of the first portion of the arch

---

*Read at the Fifty-fifth Annual Session of the American Medical Association in the Section on Practice of Medicine and approved for publication by the Executive Committee Drs J M Anders Frank Jones and W S Thayer

Thirdy, the presenile cases, forming the great majority, in which the attacks are associated with coronary artery sclerosis as part of a widespread degeneration of the vessels Hard work, mental more often than bodily, the stress and strain of modern life, excesses in diet and drink, are the factors most concerned, though why in individual cases angina should occur we can not say There is another element, as yet unknown, since in only a very small proportion of cases of coronary artery sclerosis does angina occur

Fourthly, the senile group After 70 angina is a not infrequent manifestation, a sort of terminal event in the cardiovascular degeneration Death often results from an attack, or there may be a series of paroxysms preceding a final breakdown

THE TREATMENT OF ARTERIOSCLEROSIS *

J M ANDERS, M D, LL D

Professor of Medicine and Clinical Medicine in the Medico-Chirurgical College

PHILADELPHIA

To develop the subject of the treatment of arteriosclerosis in its principal bearings, it will be necessary first to subdivide the cases into etiologic categories, as follows 1 Those due to toxic agencies in the blood, e g, in chronic alcoholism, lead poisoning, diabetes mellitus, syphilis, gout, rheumatism and other infectious diseases 2 Arteriosclerosis caused by the constant ingestion of an excess of either the carbohydrates or nitrogenous foods 3 Cases dependent on constant hypertension, due to muscular overexercise, as in certain laborious occupations and violent competitive sports 4 Aortic regurgitation, in which overfilling of the blood vessels is a concomitant, also exalted tension arising from ingestion of an excess of fluids, as in beer drinkers 5 Cases due to senile degenerative changes

With the two last-mentioned groups of cases I shall not deal at present writing, although many of the measures that will be recommended for arteriosclerosis originating in other ways tend to retard senile degeneration

PROPHYLAXIS

Prophylaxis should begin in early life, restraining enthusiasm, energy and pluck which lead to competitive efforts in the popular domain of athletics, and cripples the arterial system on which the individual must rely for work and usefulness in after life Another consideration pertains to the regulation of the occupation particularly during childhood and adolescence On the detection of any discoverable, adequate cause for the arteriosclerosis, however, early in life the aim should be to counteract or overcome them, and at the same time bring into requisition certain hygienic measures for their favorable influence in improving the metabolic processes Attention must be paid to the foodstuffs that furnish suitable products for both anabolism and catabolism Oxidation, that most important chemical process in catabolism, by means of which decomposition of albumin, sugars and fats is accomplished with fixation of oxygen, is greatly favored by well-regulated, systematic muscular exercise This is especially true of the fats, less so of the proteids The maintenance of a complete nutritive equilibrium is a potent means of preventing those pathologic processes which inevitably result in various forms of degeneration among which arterial changes are apt to be earliest manifested

GENERAL TREATMENT

In existing arteriosclerosis, each sufferer must be minutely investigated as regards the extent of the arterial changes, the tension of the pulse, condition of the heart, digestive functions and eliminative power of the kidneys

Perhaps the majority of cases are dependent on gout At all events it may be regarded as the type of the causative conditions mentioned under one and two, and in the etiology of individual cases two or more of these factors may be present together Thus the use or abuse of alcohol plays a not unimportant rôle in the arteriosclerosis of gouty subjects

HYGIENIC MEASURES.

In this class (due, as above mentioned, to toxic agencies which, in turn, are often dependent on faulty metabolism, acting as irritants of the blood) nothing is so vitally important as a suitable diet and regime There is, however, no special diet suitable for all cases of gout no dietetic rules universally applicable When the metabolic processes are abnormal they vary with the individual cases

It is highly probable that certain individuals are proof against overindulgence in foods and alcohol At least in my view, the amount of aliment that can be ingested without apparent pathologic effects differs within almost inconceivable limits in different persons On the other hand, when there is distinctly marked evidence either of gormandizing or mere overeating of either the carbohydrates or the more concentrated nitrogenous articles of diet, in gouty individuals we find that a careful regulation of the patient's dietary is obviously helpful Such subjects, in addition to manifesting gouty features, are, as a rule, plethoric, robust and often inclined to corpulency, and a rigid system of living must be enjoined A suitable and ofttimes a considerable restriction in the amount of food is a prime requisite Both fat-forming and urea-producing foods must be lessened as a rule

It is highly probable that urea which is so irritating to the kidneys, acts similarly on the coats of the blood vessels Again, granular kidneys are a not uncommon concomitant of arteriosclerosis, and when present demand a special diet

Per contra spare subjects, whose general tone is low and who are afflicted with arteriosclerosis, require a more generous diet, embracing a liberal allowance of fat-producing foods

Time and space will not permit me to enter into details concerning a podagric dietary, but broadly speaking, permissible articles of food are Whole milk, eggs butter succulent vegetables, fruits (except strawberries bananas and tomatoes) and farinacea

Of animal substances, oysters, fowl and fish (except those that contain much protein as salmon, mackerel smoked herring, halibut, salt codfish, flounders canned sardines, and the like) may be partaken of, while beef and mutton are to be employed, although cautiously Mohr and Kaufman have shown that the nitrogen excretion is quite as good for the dark as the light meats Respecting animal food, it may be said that it is beneficial rather than harmful if taken in moderate, suitable quantity

In the gouty subjects, certain waste products, as uric acid and urate of soda, are retained in the system because too little fluid is taken to hold them in solution and insure their exit from the system through the natural channels of elimination—the kidneys It is a misfortune that gouty subjects commonly fail to take water between meals On the other hand, they should be urged to do so, thus favoring the elimination of effete products through the emunctories and obviating arteriosclerotic, muscular and arthritic changes

---

*Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Practice of Medicine and approved for publication by the Executive Committee Drs J M Anders Frank Jones and W S Turner

Subjects of gouty manifestations must adopt an open-air life, coupled with regular, systematic muscular exercise, which increases the vigor and activity of the circulation, not only through the vascular system, but also through the lymph spaces and lymphatics It thus becomes an effective means of forcing from the system the waste products T Lauder Brunton[1] has emphasized the fact that the motions of the diaphragm tend to pump the lymph out of the peritoneum and pleura

The action of the heart, as Kronecker has pointed out, constitutes a sort of massage to the arteries, lungs and pericardium At each systole the blood stream drives the internal layer against the middle, and the middle against the outer, so that any fluid lying between them will be driven onward into the lymphatics *Per contra,* during the diastole, these layers will tend to separate from one another and draw fresh supplies of tissue juices from the vasa vasorum

EXERCISE

It follows that stimulation of the organic functions of respiration and circulation by systematic, wisely-regulated training will aid in the elimination of waste material and the maintenance of good, healthy nutrition of the thoracic organs and the outlying blood vessels

In arteriosclerosis the vascular tension is abnormally high, although it varies in degree Obviously, severe muscular exercise which induces and maintains a notable rise of blood pressure is inappropriate *Per contra,* mild exercise produces a slight temporary rise of blood pressure, but it falls during its continuance hence the latter form of exercise favorably influences the circulation by dilating the blood paths and thus lessening the peripheral resistance

Naturally, it is during the earlier period of arteriosclerosis, or before the changes in the arteries induce markedly increased resistance to the blood stream in the peripheral vessels, that muscular exercise produces its most beneficial effects As regards exercise in this disease, however, no hard and fast rule can be laid down.

MASSAGE

In massage we also possess a measure that by its stimulating influence on the circulation through the muscles produces an effect similar to that of muscular exercise Moreover, in this case, the heart is not called on to put forth extra exertion Indeed, the blood pressure is lessened by the use of massage, so that the heart's work is correspondingly reduced

While thus endeavoring to increase the elimination of the waste products through the kidneys, special attention should be paid to the subject of the quantitative estimation of the urea, the chlorids and other metabolic products My own studies and observations on this head show that in 80 per cent of gouty subjects the percentage of urea ordinarily contained in the urine is at least from 25 to 35 per cent below the normal

I have notes of 12 cases in which the daily output of urea had been on the average 200 grains, and under the influence of such measures as systematic physical exercise, massage and a liberal amount of simple pure water between the meals, the total daily excretion was greatly increased, even to the normal quantity in 3 of the cases

If the alternate contraction and relaxation of the voluntary muscles could be properly maintained, the return circulation through the veins as well as the lymphatic current would not require the aid of massage But unless a free circulation can be kept up by muscular exercise, carefully systematized, massage becomes imperative, since it is potent to bring about a rapid blood flow (three times more rapidly than the normal), thus preventing the deposit of micro-organisms, inorganic salts and other particles

By massage, we not only stimulate the alternate contraction of voluntary and involuntary muscles that are accessible, but also those that are inaccessible, principally by reflex action

The improvement brought about by this measure extends to the vascular system itself Edgecombe and Bain have found experimentally that while massage produces an initial rise of blood pressure, this is followed by a decided fall It was, however, found that severe massage and compression of the abdomen caused a rise of pressure occasioned by the dispersion of the blood in the splanchnic veins Massage increases the flow of lymph in a striking manner Now it is the function of the lymphatics to remove the effete matters from the tissues, they also take up the "superabundance of nutritive fluids not immediately required for the nourishment of the tissues" By remembering the principal causes of arteriosclerosis (before stated), it is clear that by a proper regulation of the séances massage becomes a most useful means of prophylaxis by stimulating the functions of the lymphatics, and it may exert a retarding influence in established cases Finally, massage also exercises a beneficial influence on the glandular secretions and the nervous system

In the disease under consideration, in which the arterial pressure is exalted, warm baths, which lower the tension both in the arteries and veins, are most serviceable They also materially assist in the process of elimination of waste materials through the sweat glands

I am fully satisfied that the agencies to which I have referred, namely an appropriate diet, systematic exercise, massage and warm baths, are of major importance as compared with the medicinal treatment in the management of this class of cases in which poisons are circulating in the blood, and these in turn dependent on perversion of metabolism

MUSCULAR STRAIN AS A FACTOR

The cases dependent on overexercise or muscular strain are numerous For this form of arteriosclerosis, the occupation is often responsible, and almost equally common are the instances occasioned by the abuse of the cardiovascular mechanism in competitive sports While possessing the power of accommodation in a high degree, the mechanism may yet be overtaxed in young subjects and the basis be laid for sclerotic changes early in life

In view of the voluminous testimony as to the injurious consequences on the heart and vessel walls of the diversified games indulged in under our modern civilization and the effects of the newer, strenuous life, it is encumbent on the medical profession to urge temperance in the matters of competitive athletics and strain, both mental and physical, without delay It has been well said that infections and accidents barred, death generally comes through arteriosclerosis[2] I hold it to be the bounden duty of the medical practitioners, who have doubtless been vividly impressed with the increasing number of cardiovascular conditions due to the general tendency in the direction of overexercise, to utter a note of warning to the public, and particularly to those having in charge our universities and other schools of learning

[2] John L. Davidson, Canadian Practitioner and Review Sept., 1901

We may well ask ourselves, do we, as a profession which is the natural teacher and guardian of the populace on the subject of physical training, manifest due solicitude for the young men of the present and future generations? In an age which furnishes numerous examples of young men who, measured by Cazala's rule, are threescore years of age, it may well be inquired, what are the causes of this decay? May not the chivalry and enthusiasm of the football field and other violent forms of competitive sports form one of the chief sources of racial decline?

In this group the important element of treatment is efficient prophylaxis Many of these cases may thus be held in check, but I have never observed a complete subsidence of the arterial changes

Pulse Tracing 1 —Case 1 before taking nitrites

Pulse Tracing 2 —Case 1 after taking nitrites four days

MEDICINAL TREATMENT

It is not within the scope of this paper to discuss the treatment of the recognized secondary affections, such as fibrous myocarditis, cirrhotic nephritis and cerebral softening, but attention is called only to the medicinal treatment of the arterial changes Individual cases, however, must be most carefully studied as regards the associated conditions, and these must receive due consideration The principle symptoms of this disease are due to a reduction of the lumen of the vessels and loss of elasticity of the coats, owing to the sclerotic changes conditions that diminish the blood supply to the various viscera

Pulse Tracing 3 —Case 1, after taking nitrites one week

It may be seriously doubted whether the disease is ever arrested by medicine We may, however, retard its progress to some extent and restore the normal rapidity of the blood current and lower the blood pressure by dilating the arterioles The remedies employed for this purpose are nitroglycerin the nitrites and potassium iodid

THE IODIDS

According to certain writers, the validity of the claims of the iodids has not been definitely shown, but they have long been lauded by others in the treatment of arteriosclerosis Except in cases due to syphilis, the results are in no wise comparable in brilliance to those following the careful application of hygienic measures mentioned above, and the use of the nitrites Billings says[3] "The iodids that have been so commonly used I have no confidence in, excepting in syphilitic cases" I have had considerable experience of their use in this disease, enough to allow of the inference that the long continued use of the iodids is serviceable, in some cases at least I hold that the iodids are without value as a means of reducing the vascular overtension, in the presclerotic stage In marked arteriosclerosis, however, iodin preparations exert a "resolvent action by stimulating phagocytosis" (M Huchard) This conclusion is corroborated by the available experience of other observers, but unfortunately these can not be submitted here for lack of time and space

Pulse Tracing 4 —Case 2 before taking nitrites

It is difficult, however, to interpret the results obtained from the use of the iodids, since it not seldom happens that noticeable remissions in the arterial tension are seen during periods in which no special treatment is employed We are sadly in need of reliable data that shall indicate their precise influence more especially in diminishing the arterial resistance

Obviously, the iodids are called for, and extended observations have shown them to be of decided value in cases showing a luetic taint The use of nitroglycerin and the nitrites to relieve high arterial tension is a customary practice among clinicians During clinical observations of the pulse, the palpating finger is sensible of variations in the tension, but it fails to convey precise knowledge as to the extent of the fall resulting from treatment

I have appended a few spygmographic tracings which indicate the results of treatment with nitrites and nitroglycerin in the arteriosclerosis of chronic Bright's disease, as well as that associated with other conditions A glance at these tracings will convey to the observer a better idea of the degree of lowering of the blood tension than is furnished by palpation of the radial and other accessible arteries For the sake of clearness brief notes[4] of three cases experimented on will also be given

Case 1 —R F, aged 68 years, colored, weight 120 pounds height 5 feet 2 inches, single, a patient in the Philadelphia Hospital He had used beer, gin and whisky to excess since the twentieth year of life His mother died of phthisis and his father of dropsy, following asthma Patient had had acute rheumatism ten years previously and had been subject to renal asthma and palpitation for four years The physical signs indicate a moderate degree of emphysema and cardiac hypertrophy, the arteries are cord like and the tension high The urine is of low specific gravity (1006), contains a small percentage of albumin, but no casts

Strychnin, which had been administered for several weeks was discontinued and a careful pulse tracing made (See Pulse tracing 1) The following preparation, highly recommended by M Huchard,[5] was then given Sodii nitrite gr xxx potassii nitratis dr 2 ss, sodii bicarb dr 5, aq destil oz x, M S oz ss t i d

---

[3] International Medical Magazine May 1893

[4] I am much indebted to Dr Wm E Hughes from whose service Cases 1 2 and 3 were selected for permission to make these observations

[5] New York Medical Journal Oct 21 1903 p 804

After the lapse of four days a tracing was taken (Tracing 2), and at the end of seven days another (Tracing 3)

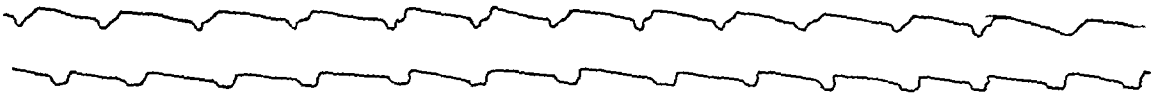
A comparison of Tracing 1 with Tracing 3 will show that the height of the primary, ascending wave or upstroke is distinctly greater for the latter than for the former This would indicate greater distension of the elastic walls of the vessels as the result of the use of the nitrites Again, the dicrotic wave, which is scarcely noticeable in Tracing 1, is more prominent in Tracing 3, and slight post-dicrotic waves are also observed From this effect on the pulse tracing we may infer that more efficient propagation of the blood current to the capillaries is the result of the treatment Unfortunately, the patient now voluntarily left the hospital and was lost sight of

Pulse Tracing 5—Case 2 after taking nitrites one week

CASE 2—W H., aged 61 years, weight 135 pounds height 5 feet 1 inch, a native American admitted into the Philadelphia Hospital He had smoked since his ninth year, and had been guilty of excessive indulgence in gin for a considerable period of time The family history revealed nothing of etiologic importance. Patient had had diseases of childhood At the age of 40 years, he fell from a building (32 feet in height), in this accident he sustained a fracture of the clavicle and several ribs, and at present his thorax is greatly deformed (dorsal kyphosis) Had rheumatism (subacute) in 1902, and also since then at intervals In the spring of 1903 was troubled with dyspnea on exertion and malleolar edema

Pulse Tracing 7—Case 2, after taking nitroglycerin four days.

The physical signs on admission show arteriosclerosis combined with an aortic stenotic murmur and tense pulse, and moderately hard arterial walls The nitrite (formula above) was employed. Tracing 4 was made prior to its use, and Tracing 5 after it had been administered for one week



Pulse Tracing 9—Case 3 right and left radial arteries after taking drop doses of aconite three times a day

A comparison of these two tracings will show that a striking change was produced by the remedy, chiefly in the direction of the lowered blood tension This was also appreciable to palpation at intervals Tracing 6 was made two days after the nitrite was withdrawn in Case 2, thus showing that its favorable effects are not permanent.

The patient was now put on nitroglycerin gr 1/100, increased to gr 1/50 t i d, and at the end of four days Tracing 7, which closely resembles the original tracing, was made

Pulse Tracing 10—Case 3 left radial after taking nitrites one week.

After the lapse of ten days more, or a two weeks' course of nitroglycerin (gr 1/50 q d during the second week) Tracings 7a and 7b were made

While this remedy has considerably modified the original tracing, it exerted a less favorable influence by far than the nitrites (vide Tracing 5), although it is probable that the dose was not large enough

CASE 3—G B T, native of United States, aged 42 years, widower, height 5 feet 10 inches, weight 150 pounds, occupation, trackman The following is, in brief, the family history Mother died of cardiac dropsy, father of kidney trouble, one brother of heart disease and another of pneumonia Patient had had diseases of childhood, acute rheumatism in 1888 and at various times since then, also several bad attacks of la grippe The patient had worked laboriously and used alcohol to excess for twenty years, there is no history of syphilitic infection obtainable The illness for which he was admitted began two weeks previously as rheumatism of ankles, hips and shoulders

The physical examination on admission indicates an existing double valvular lesion, namely, mitral regurgitation and aortic stenosis The arteries were palpable, moderately hard and quite tense, and the tension of his right radial appeared to be greater than that of the left This is also shown in Tracings 8 and 9, the former being that of his right and the latter of the left radial artery This patient had been taking drop doses of the tincture of aconite thrice daily

Pulse Tracing 6—Case 2 after nitrites had been discontinued for two days

At the end of one week of treatment with the nitrite solution, Tracing 10 (which see) was made from left radial, and indicated a decided modification of the tension as the result[6]

Pulse Tracing 8—Case 2, after taking nitroglycerin two weeks

Without stopping to multiply instances, it may be further remarked that the results of these sphygmographic studies made clear the difference between various conditions described under the title of arteriosclerosis Thus the blood pressure is not materially increased in many cases dependent on senile degeneration and the same is true of those that arise in chronic diabetes and certain toxemias Again, the nitrites whose action is so striking in lowering exalted tension are strongly indicated and most effective in that category of cases in which there is an early and marked increase in the arterial pressure, and the heart as a consequence hypertrophied

They are often found in association with disturbances of the metabolic processes (e g, gout) and in the hyperplasia for which constant muscular strain is responsible, after removal of the cause One further point remains to be emphasized it is that in the most skilled hands sphygmographic records differ, "not only in different persons, but also on successive applications to the same person"

All instances treated either by the nitrites or the nitroglycerin in ascending doses, taught the practical lesson that while a favorable effect is exerted promptly by these remedies persistence over long periods of time is a prime necessity, otherwise the improvement gained will be speedily lost

---

[6] The diagnosis of obscure aortic aneurism had been tentatively made during life owing to the differences in the pulse tracings on the two sides but the patient subsequently died, and the autopsy did not show the presence of an aneurism

DISCUSSION

ON THE PAPERS BY DRS THAYER AND BRUSH, DRENNEN, DOCK, BILLINGS, CABOT, OSLER AND ANDERS

Dr Alfred Stengel, Philadelphia—The subject of arteriosclerosis presents itself to physicians in a somewhat different light from that in which it appears to the pathologist In practical medicine we recognize it as a disease resulting from a number of causes and of importance as an intermediary condition that determines a great variety of organic diseases It is of comparatively little importance to be able to recognize arterial disease when angina pectoris, interstitial nephritis, a high grade of chronic myocarditis, or some form of central nervous disease has developed If we are to accomplish much in the treatment of the disease, it must be recognized at an earlier stage, and from this point of view two questions are of essential importance The diagnosis by direct examination and the recognition of the etiologic factors The causation is somewhat uncertain and notwithstanding the evidence brought forward by Dr Cabot, I confess myself still convinced that alcohol is an important factor, other causes of importance are overexertion in athletics and in laborious occupations, chronic toxemias and infections The importance of these latter conditions lies in the fact that they may be controlled to a certain extent, more at least than the habits of individuals I have had occasion elsewhere to state that in acute infectious diseases, when the heart and blood vessels have suffered during the attack a seemingly complete recovery may ensue, but subsequently under some stress or strain the dormant conditions in the vascular system again become apparent and advance progressively The importance of this is that the convalescence of such diseases should be conducted with greater care than has been customary in the past I remember the feeling of surprise with which I read the statement of a prominent physician speaking at a meeting of the British Medical Association to the effect that convalescence from typhoid fever should be considered to extend over the period of a year or longer and that by the exercise of care during this prolonged period the end results of the disease could be obviated The more I grow in experience of this disease, the more I become impressed with the soundness of this view Overexertion, cares and strains of all kinds should be avoided for a very long period after all of the infectious diseases, but notably after typhoid fever With regard to athletics, my experience extends over a period of some thirteen years and I have become convinced that not rarely excessive and ill directed physical exertion may lay the foundations for cardiovascular disease that may perhaps be dormant in the more active period of life, but becomes pronounced when the power of compensation begins to grow feebler with advancing age Athletics must be controlled and properly directed if good and not harm is to come from such sports With regard to the direct diagnosis of the condition, there are certain functional changes in the circulation, notably a sustained arterial pressure and a lengthening of the first heart sound, which are among the earliest physical signs The diagnosis at a period when the disease has become well established and of an advanced stage is readily made, but the recognition in the beginning is generally difficult and often quite impossible

Dr F C Shattuck, Boston—The multiplicity of the causes of arteriosclerosis has been brought prominently before us this morning, an illustration of the fact which age and experience brings home to us all—that causes in medicine are seldom single A diseased state is generally the result of several factors, the relative importance of each not being always easy to measure It seems to me Dr Cabot has shown clearly that alcoholic excess is not alone and by itself a cause of arteriosclerosis But he has not shown that it is not and may not be a contributing cause, perhaps potent His statistics deal with a single class, pauper drunkards, men who have not led lives of intellectual activity or of mental or physical strain Observation has led me to suspect that worry and the strenuous life, especially as we see it in business and some professional men, lead through defective metabolism to increased arterial tension and the widespread changes of arteriosclerosis Statistics in absolute proof of this matter are not easy, if possible, to collect In this class may not alcohol hasten and heighten arteriosclerosis? And is not this the class in which arteriosclerosis is oftenest seen? The men who tolerate alcohol best are not the brain workers and weight carriers They are men who work with their muscles outdoors, or whose occupations, temperament and environment do not involve continued strain The relation of climate to toleration of alcohol can not be ignored In fine, we really know but little about the genesis of arteriosclerosis save that it is a matter of great complexity

Dr William Krauss, Memphis, Tenn—The anatomic classification of this disease is fraught with difficulty When you recall the amount of work which has been fruitlessly expended on differentiating between croupous and diphtheritic inflammation, you can understand what I mean Dr Welch has given us a beautiful lecture He has shown us that essential arteriosclerosis is associated with changes in the intima whereby there is a division of the internal elastic lamina and a proliferation between the two layers It was Thoma who pointed out that a giving way under pressure of the outer coats of the blood vessels is what calls for other means of getting contraction, hence there is a request for an overgrowth of connective tissue in the intima to overcome that dilatation Etiologically we find the disease associated with causes that result primarily in the circulation in the body fluids of toxins producing parenchymatous degenerations in the solid organs, and it is not too much to assume that similar changes take place in the heart and vessels This primary dilatation is not so much the result of increased pressure as of diminished resistance from injury to the elastic and muscular elements in the media There may also be disease of the kidneys, and this brings up the practical inseparability of the two For instance Dr Thayer mentions malaria as a cause, but malarial fever must be severe and of long duration to produce such grave changes, and in all such cases we have fibrosis in the kidneys Severe malarial fever is also usually associated with temporary albuminuria, which permits the assumption of parenchymatous changes in the kidneys I know a man who had yellow fever twenty five years ago with suppression of the urine, that man can not drink alcohol to day without raising his blood pressure to such an extent as to cause violent throbbing in his temples, these are the people in whom alcohol will produce changes in the blood vessels There are great difficulties in the way of an etiologic classification, as attempted by Dr Thayer, from histories of cases the subjects of which have left the hospital With their present system of clinical clerks causes not heretofore recognized as factors in the disease may now be discovered It is not the diseases so much as the pathologic changes in given cases, that have a bearing on the etiology Certain irritants in the blood stream may produce inflammation in the intima and cause a proliferation resulting in intimal thickening, this may possibly be caused by the uninterrupted use of mercury as suggested by Dr Drennen When considering this problem of syphilis I should prefer to evade the lines laid down in the symposium and study syphilitic disease of the vessels as a whole Then we can classify this with Heller's *aortitis luetica*, later gummatous changes from infection through the lymphatics in the periphery, and confined to the adventitia mostly and seen in smaller arteries, next the endarteritis obliterans which occurs in still smaller vessels, and finally essential arteriosclerosis, which is more or less diffuse

Dr Charles G Stockton, Buffalo—I shall confine myself to two points and first reiterate the importance of a matter in relation to pain in the abdomen depending on arteriosclerosis which oftentimes is not suspected Such a pain not infrequently occurs as the result of the disease of the heart muscle depending on arteriosclerosis, when abdominal pain does occur in such cases the disease will be found to be rather far advanced I have seen a number of such cases and some of them I have reported All probably have noticed the abdominal pain which occurs in those who have no palpable thickening of the arteries, but which depend on arteriosclerosis In regard to the treatment, I do not think there is any doubt at all that the matter of treatment should be considered before changes have resulted in the arteries, or before the arteries have revealed changes that direct our attention to them Nevertheless I believe that when the gross lesions have appeared the condition is not absolutely hopeless, and I have pointed out that such cases are the ones the average physician will be called on to treat, for they make up a large group Some years ago it occurred to me to place non syphilitic cases who were able to lead lives marked out for them under proper management as to dietetics, exercise, medication, etc, and see what would happen Naturally this group was not large, but it offered some encouragement. I will not go into the detailed histories of these cases, but I have in mind three who were under this treatment for from between five and seven years, they had marked arteriosclerosis and manifested renal lesions and in one case there were certain suspicious central nervous symptoms These patients are still living and enjoying better health to-day than when they came under observation The plan of treatment was very simple and the same plan was adopted for all There was a restricted diet regulated exercise, the amount of fluid taken was regulated as was the amount of alcohol, and finally was followed by the systematic use of baths that would have a tendency to dilate the arterioles and capillaries without producing a general relaxation Instead of using the ordinary warm baths better results were obtained from short hot air or vapor baths, not for their eliminative effect so much as for the purpose of opening up the capillary vessels As to the use of drugs, I think that doctors differ as to the exact time when nitrites or nitroglycerin should be given In my experience I have found it necessary to give these drugs frequently if I wish to obtain a uniform effect It is far better to give them very frequently rather than two or three times a day This rule applies to the use of any nitrite I do not think the gentlemen need be alarmed when I say that nitroglycerin should be used every hour It should be remembered that patients soon become tolerant of nitroglycerin With regard to the iodids, I believe that without them we will not have successes in cases of arteriosclerosis The long continued use of the iodids the hot or vapor baths, nitroglycerin in frequent and proper doses, are all important in the treatment of arteriosclerosis in which so little stride has been made in therapeutics

Dr. S J Meltzer, New York City—Dr Thayer drew his conclusions from the conditions of the radial artery and one of his conclusions was that work, manual work, is the most essential factor in the production of arteriosclerosis It is necessary to distinguish between general and local arteriosclerosis The latter might be produced by local causes, among which we might mention (1) continued injury of a certain part, and (2) increased activity of that part. With increased activity of an organ there is a greater flow of blood through it, which is a potent factor in the production of arteriosclerosis Now, in manual work both mentioned factors are operative in the production of a local arteriosclerosis in the vessels of hand and arm, there is continual injury and increased activity which might favor an early development of arteriosclerosis in the radial artery But the presence of this localized arteriosclerosis alone can hardly be taken as an unmistakable indication of the existence of general arteriosclerosis The same argument holds good for the reversed condition, the absence of a sclerosed radial artery is no proof of the absence of an arteriosclerosis elsewhere, and the absence of a sclerosed radial artery in syphilitics who have never done manual work is no proof of their not having extensive arteriosclerosis elsewhere in the body With regard to alcohol, I wish to express great admiration for the straightforwardness with which Dr Cabot has given us his results. Dr Cabot has done much work on alcohol and his results led him to views which made him a *persona grata* in Massachusetts and elsewhere with men and women who are averse to the use of alcohol in health and in sickness I am afraid that Dr Cabot's assertion that arteriosclerosis in alcohol is a myth will be misinterpreted by this same unscientific class of public agitators. As to the correctness of his conclusions I have some doubts He stated that in the autopsies the peripheral arteries were examined He did not state that the arteries belonging to the splanchnic area were also examined We have heard to-day, in the masterly paper on the pathology of arteriosclerosis, that according to Romberg and his school it is in the splanchnic area that arteriosclerosis is liable to occur If that is so, and if Dr Cabot has not examined the splanchnic area, his conclusions that alcohol does not lead to arteriosclerosis would not yet be well supported I have a personal interest in that question Two years ago, in a paper read in Boston, I went on record in favor of the use of alcohol in disease I stated then that the effect of alcohol on the circulation is not to influence the blood pressure, but the distribution of the blood Alcohol does not increase the blood pressure, but everybody knows that alcohol causes a dilatation of the cutaneous vessels Now if these vessels are dilated while the blood pressure remains the same, there must be a compensatory constriction of the vessels somewhere in the body I suggested then that this takes place in the vessels of the splanchnic area And it is perhaps essentially in these vessels where alcohol causes sclerosis In the above mentioned paper I stated that alcohol in health is sometimes a curse, alcohol in disease is often a blessing In repeating it I would now state alcohol in disease is often a blessing, alcohol in health is very often a curse

Dr Robert H Babcock, Chicago—The thoughts I had in mind have been so clearly presented by Dr Shattuck that, as a matter of fact, he has taken the wind out of my sails I should say, however, in regard to alcohol, that convincing as Dr Cabot's statements appear to be, they impress me as not convincing in their refutation of the etiologic influence usually attributed to alcohol and as emphasizing the error likely to occur from the attempt to consider any one factor by itself For example, the case he reported was of a young man who took a quart of whisky daily for ten years Now theoretically that may be all right, but is it quite fair in estimating the influence of alcohol to draw conclusions from such a case? To be sure, whisky contains about 50 per cent of alcohol, but there may be other forms of alcoholic drinks which may be more injurious than whisky For instance, there are Germans who consume 25 to 30 liters of beer daily, and when our German confrères estimate the influence of alcohol in the production of arteriosclerosis they attribute importance not alone to the alcohol, but to other factors residing in the consumption of such enormous quantities of beer These are the intake of excessive amounts of fluid and the large percentage of nutritive material contained in the beer It is asserted by some, notably French writers, that alcohol in excess produces hypertrophy of the heart The Germans, on the other hand, as Krehl believe that such is not the case, that alcohol in concentrated form occasions not hypertrophy, but fatty degeneration but that hypertrophy may result from excessive use of beer and this only in consequence of the large amount of nutritive material and fluid taken into the system So I apprehend it may be as regards arteriosclerosis There must be something else in addition to the alcohol if chronic alcoholism is to set up arterial changes There is I believe, an element of strain on the vessels which must be considered when individuals consume 25 to 30 liters of beer daily It is particularly strain of an intermittent kind which has a causative influence, and in the consumption of large quantities of alcohol the strain exerted is of an intermittent sort. Dr Welch emphasized the fact that arteriosclerosis may be endured for many years without shortening life I desire to add that it is the individuals with arteriosclerosis who are thin who often reach advanced age, whereas, those persons whose arteriosclerosis is associated with corpulence are especially liable to be cut short in the prime of life from some of the visceral changes depending on or connected with vascular decay In such persons we are apt to recognize hypertrophy of the heart and oftentimes sclerosis of the coronary arteries.

Dr. F R. Weber, Milwaukee—I think that we have all come to the conclusion that the pathogenesis of arteriosclerosis in its various forms concerns itself primarily with changes in the arteriomuscular system and secondarily with changes in the intima We must study simple parenchyma—protoplasm of the muscle cell—and chemically consider its life nucleus and its receptors or side chains These receptors partake of the characteristics of the aldehyde and amine groups If we are to write the history of arteriosclerosis we must go back to simple chemistry, and to the action of nutrient and toxic agents on protoplasm Living protoplasm has the capacity for intense chemic reactions, and Loew has made a clever attempt at the classification of toxic agents 1 Agents acting by chemical substitution Thus the phenols react easily with the aldehyde group, and others with the amine group 2 Oxidizing agents like permanganate of potash, phosphorus, arsenic, etc 3 Catalytic toxic agents like chloroform, ether, alcohol, chloral hydrate, etc, of no intense chemical activity and yet of large toxic power 4 Protein bodies readily unite with bases, acids and alkalies Lead may enter thus and organic life deteriorate Sodium chlorid, potassium chlorid and many other salts are concerned in osmotic pressure Barium chlorid, like adrenalin, has a direct action on the walls of the arteries and increases blood pressure Administered experimentally for a length of time it produces obliterating endarteritis In conclusion we mention toxic organic bases, especially toxins and proteins which react specifically with living protoplasm A more complete system of toxicology as regards living protoplasm, and experimental work along these lines in laboratories of research, will solve the question of arteriosclerosis and aid in its prevention

Dr Boardman Reed, Philadelphia—There is one point which has been overlooked in the consideration of arteriosclerosis, and that is the matter of the dosage of alcohol Dr Cabot has proved that large doses, a pint to a quart of alcohol taken daily by old topers, do not apparently cause an undue percentage of arteriosclerosis, and it seems to me that this is not incompatible with the views generally held that alcohol may at least indirectly produce that disease It is probable, in my opinion, that when arteriosclerosis is produced, in persons who drink alcoholic beverages it is indirectly and through the gastrointestinal tract We know that alcohol is a poison to protoplasm and all the glandular structures, the liver, gastric glands, etc, that alcoholic beverages in the usual doses have the effect of lowering the action of the gastric glands Therefore, an injurious effect of alcohol on the arteries can be proved, since it is also an established fact that one way in which arteriosclerosis can be set up, is through toxins formed in the alimentary tract. Alcohol impairs digestion and thus indirectly causes arteriosclerosis, but, it is also known that when one drinks largely of alcohol in concentrated form, as in whisky or gin, less fermentation of putrefaction results than in the case of moderate beer or wine drinkers All clinicians have noted that when a man is indulging largely in alcohol he takes but little food, and only a small amount of indican may appear in the urine Therefore, may it not be concluded that the more usual indulgence in alcohol can produce arteriosclerosis through its effect on digestion? Whisky soaked men may escape the danger in this form because they partake so sparingly of food They live practically on alcohol, which is an antiseptic and present less indican in the urine, and less of the other products of a faulty metabolism than moderate drinkers The large amounts of concentrated spirits poison them in other ways, but may tend less to the production of arteriosclerosis than wine and beer in the usual quantities

Dr Henry Sewall, Denver—One of the most widespread applications of clinical observation in medicine to day is to be found in the use of certain instruments for measuring the human blood pressure These instruments are, for the most part, too one-sided or incomplete in their usefulness, they usually measure solely either the systolic or the diastolic blood pressure I was very glad to hear Dr Anders dwell on the physiologic function of the phases of heart activity, as a clinical register of arterial blood pressure and its variation, a thing that is so apt to be disregarded The pulse seems to me to manifest two different characters, either of which may indicate the presence of arteriosclerosis (1) a pulse of continuous high tension and incompressibility, (2) a pulse unaccompanied by any valvular lesion, which is hard and has a high tension at the acme of the pulse wave, but which almost collapses with diastole of the heart Now, as regards the nutrition of the tissues in general and of the arteries in particular, what are the relations of systolic, diastolic and mean arterial blood pressure? The respective values of these physiologic phases of blood pressure probably have intimate relations both to the development and effects of the pathologic condition of arteriosclerosis

Dr A McPhedran, Toronto, Canada—I desire to correct a statement made by a previous speaker by pointing out that the consumption of alcohol *per capita* in Canada is reported to be less than in any other civilized country As to the effects of alcohol on the arterial system, it is of interest to refer to a discussion which took place at the British Medical Association a few years ago in regard to an epidemic of neuritis among beer drinkers in the midland counties of England It was found on investigation that the disease was produced by arsenic with which the beer was contaminated Sir William Gairdner of Glasgow said that while whisky was much drunk in his city, he had never seen a case of alcoholic neuritis It is evident that some accessory condition is necessary to enable alcohol to produce either neuritis or arteriosclerosis It is worthy of note also that a variability in the vitality of tissue exists in different persons, and that to this may be ascribed the occurrence of disease in some while others escape As to the effects of overstrain it seems certain that a continual strain is much more injurious than an intermittent strain In the days when the British soldier had to carry his knapsack, and walk in a constrained attitude, aneurism was of much more frequent occurrence than now when the utmost freedom of body is allowed

Dr A Jacobi, New York City—I should like to ask Dr Thayer the ages of the patients who had typhoid fever and who later developed arteriosclerosis Next What can we do with those cases of arteriosclerosis dependent on syphilis? Here we use mercury and the iodids, and more or less successfully That is why it strikes me as too sweeping to attribute some symptoms of arteriosclerosis to the use of mercury I believe most of us use mercury and the iodids whenever we have such a case of arteriosclerosis of syphilitic origin Dr Welch said that one of the causes of hypertrophy of the heart was local obstruction, he said this when speaking of arteriosclerosis as a cause of myocarditis We should not look for one cause in the production of cardiac hypertrophy, there may be a combination of circumstances and a number of causes working in the same direction Among the cases are the following There are the cases studied by Gèrmain Sée, Virchow and others, of congenital smallness of large and small arteries all over the body, which cause a peculiar form of congenital chlorosis of women and sometimes men, which appears to depend on nothing but this original smallness of the arch of the aorta and the arteries in general, this may give rise to obstruction in the peripheral circulation In connection with this condition there is frequently no hypertrophy The heart may even be small, while at the same time the arteries are small or a heart of normal size with the structure not absolutely normal, the muscle may be flabby and sometimes there is a fatty degeneration In cases of pernicious anemia, where this condition is sometimes found, there is at work another cause So I think it is well worth while to doubt in connection with many cases whether the contraction of the arteries or the local obstruction in the arteries would be by itself a sufficient single cause of the hypertrophy It does not appear to be so

Dr W S Thayer—I agree with Dr Meltzer that one must make many reservations before applying figures which relate only to palpable radial arteries, to arteriosclerosis in general As I have already stated, however, it seems to me probable—and I think most clinicians will agree with me—that changes in radial arteries sufficient to justify a note in the course of a routine ward visit, in individuals under 40 or 50 years of age, are associated in a considerable proportion of cases, with sclerotic changes elsewhere Our figures and our conclusions, however, relate entirely to the palpability of the radial arteries

Dr C Travis Drennen—I am grateful to Dr Jacobi for what he has stated regarding the use of mercury in syphilis The purpose of this paper was not to disparage the use of mercury, but to protest against the methods which are and have been commonly adopted by the profession at large for many years of administering mercury for practically many years without interruption

Dr. Richard Cabot—I think that we can not accurately determine the diastolic blood pressure with Stanton's modification of the Riva Rocci instrument, but that we can measure it with an accuracy sufficient for the purposes for which the instrument is likely to be used While I have not sufficient experience to take issue with the views expressed about competitive athletics, I should like to refer the gentlemen to the March number of the *Harvard Graduates' Magazine* where there are some statistics of importance on the health of Harvard oarsmen Rowing is a form of immoderate athletics, if there is any, but the heart and arteries in these statistics do not show changes confirmatory of what has been stated I certainly agree with what Drs Shattuck and Babcock have said regarding multiplicity of the causes of arteriosclerosis The activity of alcohol as a cause acting alone I have not been able to perceive Replying to Dr Meltzer at the Massachusetts General Hospital autopsies the splanchnic area was investigated and none of the changes referred to was found I agree with Dr Meltzer, alcohol is a curse in health whether in large or in small quantities, and I act on that belief but when one is making investigations or doing research work he must confess to what he finds What I found was absolutely opposite to what was expected, and I gave the figures as I found them

---

THE RELATION OF CHEST CONTOUR TO LUNG CAPACITY *

FRANCIS FREDERICK MALONE, M S, M D
Department of Physiology Northwestern University Medical School
CHICAGO

Early in the history of medicine clinicians recognized that the shape of the chest varies in disease Thus the emphysematous or "barrel-shaped" chest, the phthisical or flat chest, and the various unilateral deformities of pleurisies, etc, are mentioned under various names by eminent writers

Apparently, however, the fact that the contour of the chest varied in different individuals not subject to disease was not recognized or was considered of no value until in the beginning of the last century, when Chomel[1] published the first work on thoracic diameters and insisted that diameters and not circumference were the true basis for estimating lung capacity The next publication along this line was by Fourmentin,[2] who, working along the lines of Chomel, determined the "thoracic index," using the formula adopted by craniologists in determining the cephalic index, i e

$$\frac{\text{Transverse diameter} \times 100}{\text{Dorsoventral diameter}} = \text{index}$$

This he found to vary for apparently normal individuals between 120 and 140 and states that whenever the index fell below or above these numbers the subjects were cachectic He also, by means of a modified pantagraph, obtained reduced tracings of the thorax, apparently being interested, however, in such abnormalities as pleurisies and tuberculosis only

A few years later (1884), E Maurel,[3] realizing that thoracic measurements are for the purpose of estimating lung capacity, using a cyrtometer for the purpose of making tracings of the chest contour, arrived at the following conclusions

1 "Perimeter" is not a satisfactory basis on which to estimate lung capacity because for the ellipsoidal figures having an equal perimeter the ones whose diameters most nearly approach an equal value, contains the greatest area

2 The method of estimating capacity by means of anterioposterior and transverse diameters is more accurate than by means of the perimeter

3 The most accurate method is by means of the contour area as taken by the "cyrtometer," i e, the graphic representation on cross-section paper ruled in sq cm of a shape of cross section of the chest

Maurel, also, by using the thoracic index, confirmed the finding of Fourmentin regarding the average index

Since this time numerous observations have been made by clinicians and anthropologists as regards the two diameters of the thorax, but it remained for E O Otis[4] to determine their average measurements These he gives as 7 3 inches ((18 5 cm) for the anteroposterior and 9 6 inches (24 3 cm) for the transverse diameter

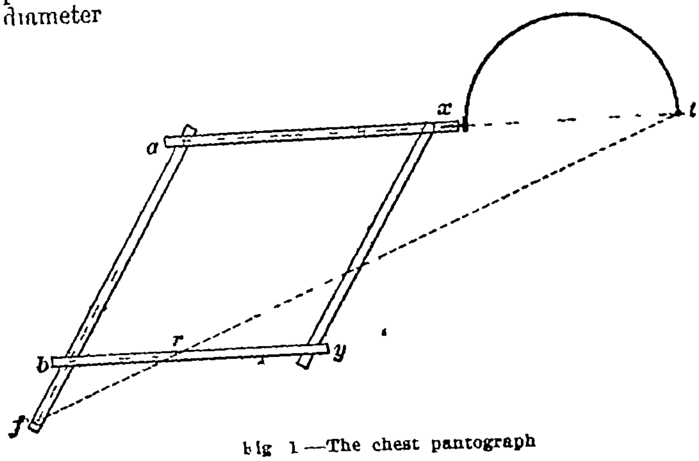


Fig 1 —The chest pantograph

In 1897 Hutchinson,[5] from measurements of enlisted men, determined the average index of the chest Instead, however, of using the index of Fourmentin he adopted the less cumbersome method of dividing the smaller (dorso-ventral) diameter by the larger (transverse) diameter By means of this formula he determined the average index to be 0 725 Contrary to the usual belief, however, he makes the following unique assertion

1 The tubercular type of chest is not a flat chest, as is usually taught, but one tending toward the round or barrel shape, basing his conclusions on the indices of the few but well-selected cases of tuberculosis the measurements of which he was able to obtain

2 The round type of chest is an undeveloped chest because of the following considerations

a A study of comparative anatomy shows that the higher we rise in the scale of mammalia the more the transverse diameter increases at the expense of the dorso-ventral

---

[5] Hutchinson Woods Some Deformities of the Chest in the Light of Its Ancestry and Growth The Journal A M A vol xxix Sept 11 1897 p 512

b The growth of the human thorax both during gestation and childhood shows a corresponding increase of the transverse at the expense of the dorso-ventral diameter

As one reviews the literature of the subject of the thoracic indices or contours, he is struck by the frequency of reference to lung capacity, but still more striking is the paucity of observations on capacity and the utter lack of data showing the relation between either indices or contours and capacity The object of the work intended in the present paper is to determine, if possible, if there is any relation between contour areas, contour indices and lung capacity

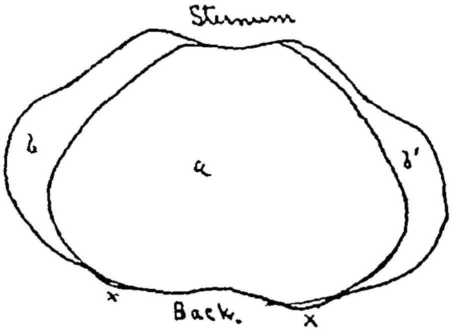

Fig 2—Superimposed tracings at expiration showing the difference in area between the broad and deep chests The broad chest is a tracing representing the contour of the chest of one of the oarsmen of the U S Lifesaving Crew at Evanston (Note the prominent latissimus dorsi muscles x and x) The tracings of the deep chest is of an individual of sedentary habits

METHODS

The data consists of observations made on 119 individuals (male), students of medicine in the medical department of Northwestern University

Observations—The observations consist of

1 Thoracic diameters

a Dorso-ventral during inspiration and expiration

b Transverse during inspiration and expiration

2 Contour areas (chest pantograms) taken at the end of inspiration and expiration

3 Contour index determined by the formula of Hutchinson dorso-ventral diameter divided by the transverse diameter

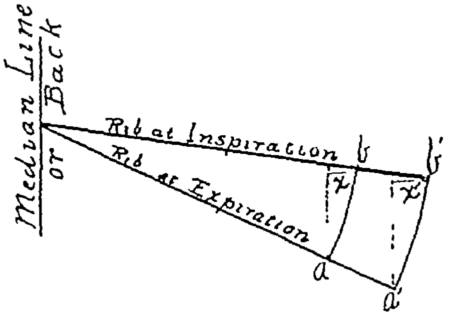

Fig 3—Illustrating geometrically the influence of increased linear dimension on relative expansion The greater the breadth or depth the greater the expansion in the dimension in question on inspiration

4 Lung capacity

The Apparatus—The diameters were taken with a pair of calipers (pelvimeters), a description of which is unnecessary The lung capacity was obtained by means of the wet spirometer

The contour-areas or cross-sections were taken by means of the chest pantograph of Hall[6] (Fig 1) This instrument consists of a modified artist's pantograph, the modification consisting of a semicircular brass rod attached to the distal angle (x) of the rectangle of the pantograph for the purpose of encircling the body, the brass rod being so attached at x as to permit of its rotating through an arc of 180 degrees, and so permits a tracing of the opposite side of the body

The apparatus is attached to a table fitted at one side with a back-rest at right angles to the edge of the table The patient, being stripped to the waist, is then seated beside the table on an adjustable stool, with his back squarely against the back-rest, and the tracing-point (T) of the brass rod then placed against the side away from the table The subject having been told to rigidly maintain his position, is instructed to exhale The tracing-point is then swept rapidly but accurately across the back to the opposite side, then turned through an angle of 180 degrees, and swept along the front of the chest until the point from which the tracing was started is reached A sheet of cross-section paper having been placed under the recording point (r) of the pantograph, this gives a tracing of the thorax in expiration If a tracing of the thorax in inspiration is desired, the patient is instructed to inhale to his full capacity, and the tracing-point is again swept back to the opposite side, i e, the one against the table Since the patient is against the back-rest all the time it is not necessary to retrace the contour of the back The cross-section or ordinate paper used was ruled in 2 mm squares and the pantograph was so arranged that the figure was reduced to one-fifth the original size, so that one square =1 sq cm

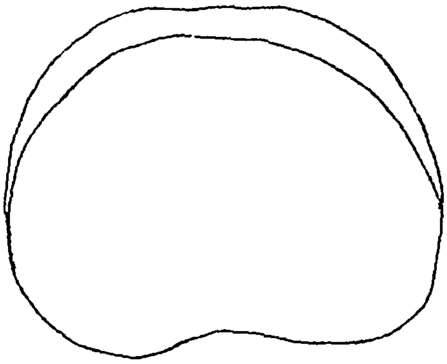

Fig 4—Tracing showing the contour of a round chested (high index) individual a druggist No athletics Note the evenness of the contour

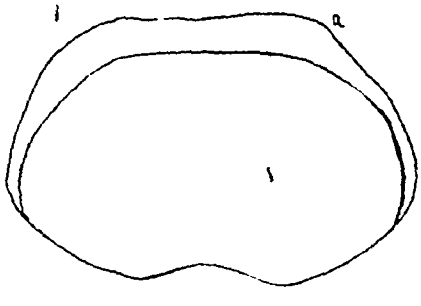

Fig 5—Tracing showing the contour of a broad chested (low index) individual, an athlete (pitcher in baseball team) Note the prominence of the right pectoral muscle (a)

This gives one a tracing which is of a convenient size for use and for filing It seems pertinent to the subject to call attention to the fact that one acquires at a single observation the following data 1, The accurate configuration of the thorax at any desired level, 2, the area at expiration and inspiration, 3, area expansion i e, the difference between area of inspiration and expiration, 4 diameters, both dorso-ventral and transverse 5 diameter expansion for both dorso-ventral and transverse, b, countour index or the ratio between the dorso-ventral and the transverse diameter

---

[6] Hall W S The Chest Pantograph THE JOURNAL A M A Feb 28 1903 vol xv p 567 and The Evaluation of Anthropometric Data THE JOURNAL A M A vol xxxvii Dec 21 1901

THE EVALUATION OF THE DATA

Instead of using the method of averages for evaluating measurements, the median value was obtained by the Hall-Quetelet[7] method, the median value being that value which is so located in the whole series of observations of a single measurement of any group, that there are as many below it as above it i e , that the number of values which it exceeds is equal to the number of values which exceed it "

TABLE 1 CLASS 1 SMALL CHESTS

The data was first transferred to cards, each card giving all the measurements of an individual Then to determine the median value of any measurement the two extremes are found Thus, for example, it is found that the height of 116 individuals varies between 152 cm and 192 cm This gives a difference of 40 cm between the shortest and the tallest individual of the series

Dividing the series into ten groups, with a difference of 4 cm , we find the following

152—156—160—164—168—172—176—180—184—188—192
1 2 6 16 35 23 16 14 2 1

Since there are 116 measurements in the series, it is necessary only to determine the fifty-eighth measurement to obtain the median value[8] This is obtained by the formula

$$M = a + d\left(\frac{\frac{n}{2} - l}{m}\right)$$

M = Median value
a = minimum value of median group (the group containing the median value)
d = difference between groups
n = total number of observations
l = sum of observations below the median group
m = number of observations in the median group
Substituting

$$M = 168 + 4\left(\frac{\frac{116}{2} - 25}{35}\right) = 170\ 6$$

In arranging the cards, they were first divided into three classes according to size, that is, according to the length of anteroposterior diameter Those having a diameter falling between 14 and 17 with a median value of 16,863 cm , were called small-chested (Class 1) Those whose dorso-ventral diameter fell between 17 and 19 (median value 18,143) were called medium-sized (Class 2), while those whose anteroposterior diameter was over 19 (median value 19 454), were called large chests (Class 3)

This in further calculation throws out of consideration the element of size which must be eliminated before area and capacity may be compared with contour

Transverse expansion	2 5 cm	2 0 cm	3 0 cm	2 1 cm	3 2 cm	3 0 cm
Lung capacity	3445 cu cm	3366 cu cm	3700 cu cm	3450 cu cm	4121 cu cm	3679 cu cm

CONCLUSIONS

A study of the results tabulated above shows the following

1 For chests of the same size, those having low indices, i e, broad chests, have a greater contour-area (cross-sectional area) both in expiration and inspiration, than do the deep chests A glance at the superimposed tracings (Fig 2) makes this plain If the area of the deep chest be represented by (*a*) the area of the broad chest must be represented by a+b+b′, i e the areas at the sides

2 Of still more importance, however, is the fact that the broad chests have an area expansion greater than that of the deep chests That the increase is small is true, but the uniformity with which the broad chest shows the greater area of expansion shows beyond question that the rule is a general one

3 For the broad chests the greater expansion is in the transverse diameter, while the deep chests have their larger expansion in the dorso-ventral diameter This is contrary to the statement of Hutchinson that the greater expansion of the broad or "bellows" type of chest is in the anteroposterior diameter

Inasmuch as the ribs move upward and outward and upward and forward during inspiration, it is readily seen that every centimeter added to either diameter increases its capacity for expansion Thus in Figure 3 if the point a is elevated to the point b, it must pass outward a distance of x, but the point a′ in being raised to the point b′ must pass outward a distance of x′, necessarily greater than x, by construction

4 Since lung capacity is a measure of volume expansion, it should follow that if the broad chests have a greater contour area and contour expansion, they should have a greater capacity The figures of the table prove beyond a doubt that the broad chests have a greater capacity, not for one size only, but for all sizes

That lung capacity (volume expansion) is the real criterion of resistance to tuberculosis has only a negative proof (persons with deficient expansion being more prone to develop tuberculosis) is conceded, yet one can not but feel justified in concluding that the person with a broad chest, with its uniformly attendant increased capacity, has the better chance of resisting the inroads of tuberculosis With this fact in view, one can not but add his plea to that of Hutchinson, for some means to develop the thorax in the transverse diameter

SUMMARY

1 By means of the contour index chests may be divided into broad and deep, having low or high indices respectively

2 For broad chests the greater expansion is in the transverse diameter

3 For deep chests the greater expansion is in the dorso-ventral diameter

4 Broad chests have a greater cross-sectional area both for inspiration and expiration, than deep chests

5 Broad chests have a greater area expansion than deep chests

6 Broad chests have a greater capacity (volume expansion) than do deep chests

7 Broad chests having uniformly a greater capacity would seem to offer greater resistance to tuberculosis

Chilblains a Tuberculous Affection—A Danish physician, G E Permin, publishes a communication in the *Ztft f Tuberkulose*, v No 5, arguing that erythema pernio, the common chilblain, is probably a tuberculous exanthem The action of cold enlarges the vessels, and this affords the toxins the opportunity to get in their work The stage of the pulmonary affection has no influence on the development of the complication

MATHEMATICAL RELATIONS OF CERTAIN CHEST MEASUREMENTS *

WINFIELD S HALL, M.D
Professor of Physiology Northwestern University Medical School
CHICAGO

During a recent investigation of 'The Relation of Chest Contours to Lung Capacity," made by Dr F F Malone,[1] in the physiologic laboratory of the Northwestern University Medical School, it occurred to me, first, that there should be a method of computing area expansion from the diameters, and second, that there should be a method of computing lung capacity from area expansion and thoracic length

The chest contours were traced through the help of the chest pantograph, which I devised[2] One of these contours is shown in Figure 1 The one chosen for this figure happens to represent a chest of unusually high index, i e, an unusually deep chest The inner line shows the contour of the chest at the end of the forced expiration, while the outer line gives the contour at the end of the forced inspiration

The cross-sectional area or contour area of the chest at inspiration or at expiration may be easily determined by inspection Each of the large squares represents 25 square centimeters, each of the small squares 1 square centimeter The area expansion is the difference in area between the contour of expiration and that of inspiration Extended observation has shown that the area expansion bears a very close relation to the lung capacity, as set forth by Malone[1] Furthermore, that it is the most important measurement that can be made on the thorax, inasmuch as it is an index of lung capacity and of extent of mobility and of the symmetry of expansion

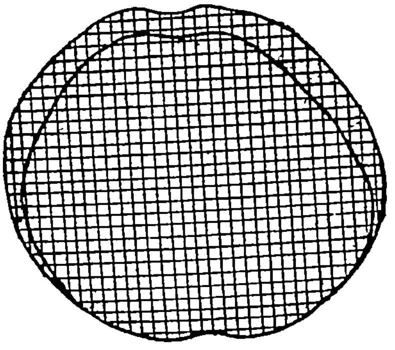

Fig 1.—Thoracic contour of R. B 5 7, 02
Dorsoventral diameter at expiration $D = 24\ 3$
Dorsoventral expansion $e = 2\ 3$
Transverse diameter at expiration $T = 28\ 5$
Transverse expansion, $e' - 2\ 5$
Contour index, $I = \frac{D}{T} = 853.$
Mid-diameter, $\frac{D+T}{2} = 26\ 4$
Radial expansion, $\propto = \frac{e+e'}{4} = 1\ 2.$
Area expansion $E = \pi \propto \left(\frac{D+T}{2} + \propto\right) = 104\ 4$
Length of thorax $L = 30\ 2$
Lung capacity $C = L \times E = 3153$ c c.
Lung capacity as measured $= 3100$ c c

There are only a few appliances with which the area expansion can be directly determined, and most of these, as in the case with the chest pantograph, while simple in construction and not very bulky, require a considerable amount of practice to acquire the accuracy necessary in such observations and are better adapted for use in laboratories and large dispensary and hospital clinics than in the private office of the practitioner

It can hardly be questioned that the contour expansion or area expansion and the lung capacity are, next to the condition of lung tissue, the most vital points to be determined in an examination of the chest But both of these determinations require apparatus not always convenient for the general practitioner to have in his private office

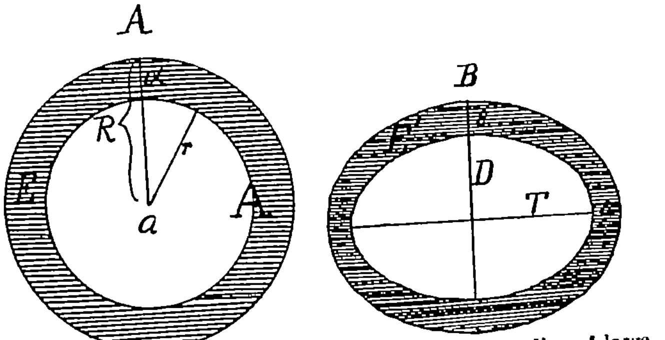

Fig 2.—Let A equal area of large circle R equal radius of large circle, a equal area of small circle, r equal radius of small circle, E equal area of shaded ring (E = A − a), $\propto$ equal the difference of radii ($\propto = R - r$) To find the area of the ring (expansion) in terms of $\propto$ and r

(1) $A = \pi R^2$
(2) $a = \pi r^2$
(3) but $R = r + \propto$
(4) $A = \pi (r + \propto)^2 = \pi (r^2 + 2r\propto + \propto^2) = \pi r^2 + 2\pi r \propto + \pi \propto^2$
(5) but $E = A - a$
(6) $E = \pi r^2 + 2\pi r \propto + \pi \propto^2 - \pi r^2 = 2\pi r \propto + \pi \propto^2$
(7) $E = \pi \propto (2r + \propto)$

In the elliptical figure (B) a very close approximation to the area can be obtained by using half the average of the two axes (D and T) in place of the radius (r) The mid diameter equals the average of the axes, $\left(\frac{D+T}{2}\right)$, and the mid radius equals half the mid-diameter, or $\frac{D+T}{4}$ Substituting this mid radius for the radius (r) in equation (7) we obtain the simple formula

(8) $E' = \pi \propto \left(2\frac{D+T}{4} + \propto\right) = \pi \propto \left(\frac{D+T}{2} + \propto\right)$

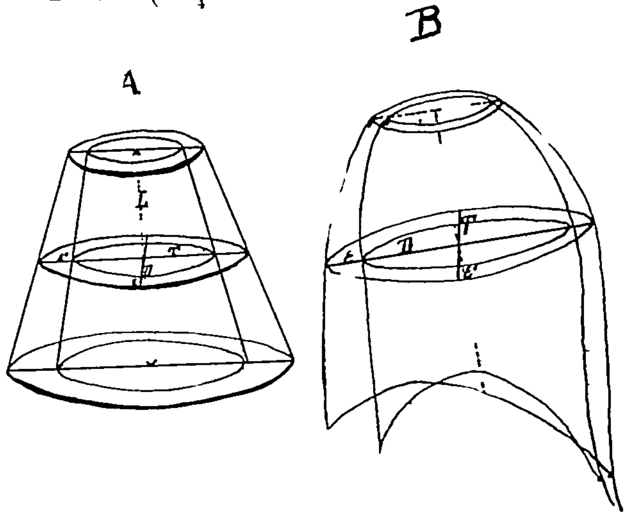

Fig 3.—A shows the frustrum of a cone to which has been added a certain volume by the increase of the diameter The added volume is equal to the average area of expansion taken at the mid height, multiplied by the altitude or length But the average area expansion $E = \pi \propto \left(\frac{D+T}{2} + \propto\right)$, and the altitude equals L.

Fig 3.—B. The similarity of the mathematical conditions of the chest to those of the geometric figure just described is apparent in the figures. The area expansion at the nipple plane approximates the average area expansion whose determination one can easily make The length L may be established by experiment Note that the act of inspiration adds something to the length as well as to the lateral dimensions

[2] Hall The Chest Pantograph THE JOURNAL A M A. Feb 28, 1903 vol. xv p. 567

It is my object to set forth briefly an accurate and simple method of determining both area expansion and lung capacity with the help of steel calipers or of the obstetrician's pelvimeter

TO DETERMINE THE AREA EXPANSION

Note that in Figure 1 the area expansion is distributed around the front and sides of the chest This is due to the fact that in the use of the chest pantograph the back of the subject rests against a fixed support This naturally throws all of the expansion of the dorso-ventral forward If the tracing has been made in such a way as to distribute the expansion evenly all around the contour of expiration it would have been quite as accurate and would have given the same area expansion, but the latter would have appeared as a complete ring rather than as a crescent

Let us compute the area of a ring between two concentric circles of unequal radii Figure 2A shows two such circles The expansion area represented by the shaded ring E equals the difference in area of the two circles (E=A—a), which we see from the mathematical reasoning (see description of figure) equals the product of three quantities very easily measured ($E=\pi$ times α times $(2r+\alpha)$)

The contour of the chest, however, approaches an ellipse rather than a circle in its outline Let us adapt the method to the ellipse This adaptation given under Figure 2B, shows that the area expansion between the ellipses is equal, within a very close approximation, to the product of three quantities, which, in turn, are determined by making three simple measurements namely 1, the dorsoventral diameter, D, 2, the transverse diameter, T and third, the average radial expansion, α

The formula $E=\pi\alpha\left(\frac{D+T}{2}+\alpha\right)$

Let us apply this simple formula to actual measurements of the human chest, and thus put it to a practical test The accompanying tables give the results from the chest measurements of 119 normal men, classified as to size into three classes, each class being subdivided into broad-chested and deep-chested groups on the basis of the contour index The contour index is obtained by dividing the dorsoventral diameter at expiration by the transverse diameter at expiration, according to the formula of Hutchinson[3] The broad chests, therefore, have lower indices than the deep chests The values given in each column represent the median values rather than the averages The advantages of the median value over the average are set forth in my paper on the "Evaluation of Anthropometric Data"[4]

Applying the formula to the value in the first column, one must first determine the value of α This being the average radial, expansion is obtained by taking one-half the average expansion of the two diameters, or one-fourth the sum $\alpha=\frac{\epsilon+\epsilon'}{4}$

Therefore the radial expansion, $\alpha=\frac{3\ 4+2\ 5}{4}=1\ 475$

The mid-diameter, $\frac{D+T}{2}=\frac{16\ 5+26\ 3}{2}=21\ 4$ The area expansion may be very easily obtained from these values $E = 3\ 1416 \times 1\ 475 \times 22\ 875 = 106$ sq cm One may simplify the multiplications without appreciably modifying the results by using approximate factors $E = 3\ 1/7 \times 1\ 48 \times 22\ 88 = 106\ 5$ sq cm, which differs from the first result by only 5 sq cm—far within the necessary error of observation

Note that the area expansion as given in the table, E is 111 sq cm This was determined graphically by the chest pantograph, and the error of observation has a range of not less than 10 sq cm, so that the area expansion, as determined by the method above described is quite as reliable as that determined by the pantograph

MATHEMATICAL RELATIONS OF CERTAIN CHEST MEASUREMENTS

Area expansion, $o=\pi\alpha\left(\frac{D+T}{2}+a\right)$	106 5 sq cm	105 5 sq cm	121 0 sq cm	115 0 sq cm	132 5 sq cm	131 5 sq cm	118 2
Thoracic length index $=\frac{C}{o}=\frac{C}{o'}$	32 3 / 31 0 = 31 65	31 9 / 31 1 = 31 5	30 6 / 31 3 = 30 95	30 0 / 31 0 = 30 5	31 0 / 30 9 = 30 95	28 0 / 29 9 = 2895	30 7
Length of thorax	32 8	32 4	32 3	32 0	32 5	31 4	32 3
Height sitting	91 0	90 8	90 3	90 9	91 0	89 1	90 52

It may be interesting to note in this connection that the average area expansion as determined by the pantograph—117 3—differs from the average—118 2—as determined by the calipers and the formula by only 9 sq cm, a very close approximation on 119 individuals (See column of averages)

To apply the formula to the individual case one may take the measurements as given in Figure 1 The mid-diameter equals 26 4, the radial expansion 1 2, the area expansion equals 3 1416×1 2×27 6=104 sq cm An inspection of the figure shows the area expansion is more than 100 and less than 110 The determination by calipers is quite as accurate as that by the graphic pantograph method

TO DETERMINE THE LUNG CAPACITY

The usual method to find the lung capacity is to direct the subject to fill the lungs to the maximum, then exhale as much as possible, forcing the air into the spirometer where it is measured During the act the thoracic wall changes from the position of forced inspiration to that of forced expiration, thus decreased in cross-sectional area to the extent of the area expansion

[3] Hutchinson Some Deformities of the Chest in the Light of Ancestry and Growth THE JOURNAL A M A Sept 11, 1897 vol xxix, p 512

[4] Hall The Evaluation of Anthropometric Data, THE JOURNAL A M A, Dec 21, 1901 vol xxxvii

A study of Figure 3 will make it evident that lung capacity, C, is equal to the increased volume of the chest in inspiration, i e, to area expansion, E, times length $C = E \times L$

One can measure the distance between any two landmarks accessible on the surface of the thorax, but, having measured it, he is unable to affirm that it is equal to the average length The difficulty of locating landmarks which may be accepted as the limit of chest length led me to the use of an indirect method which it is hoped, will lead to satisfactory results

The final object is to find lung capacity without the use of the spirometer The laboratory, however, is supplied with a very accurate water spirometer Lung capacity is not, then, an unknown quantity It is chest length that is the unknown quantity in the simple equation $C = E \times L$ Then $L = \frac{C}{E}$

Let us call L the thoracic length index, and apply the formula to the values in the table The table gives two values for area expansions—E, found by the graphic method with the pantograph, E, found by the mathematic method with the calipers Inasmuch as both of these are subject to a certain range of error, and we have no means of knowing which is the more accurate, we will arrive at more reliable results by using both values in turn to determine the thoracic length index, and finally adopting the average

In the first column this average length index is 31 65 cm Note from the table that the values vary within a very narrow range, and that the average for the 119 men is 30 7 cm

At the time the data was collected (1902) the thought of taking thoracic length had not occurred to me The height sitting was taken, however, and is shown in the table The average for the 119 men is 90 52 cm In order to get an idea of the length of the thorax of these men, the height sitting and thoracic length was measured in nine men taken at random The thoracic length was measured from the middle of the clavicle downward along the ventral wall of the thorax to the middle of the tenth rib, where it joins its costal cartilage In the nine men thus measured the thoracic length was 35 7 per cent. of the height sitting, Taking this per cent of the height sitting for the thoracic length (calculated), it gives us the values recorded in the table

This calculated thoracic length serves the purpose of showing that there is a definite relation between the thoracic length index and the measured thoracic length

The average thoracic length index for 119 men is 30 7 cm. The average thoracic length (calculated) is 32 3 cm These averages differ by 1 6 cm If the thoracic length were taken from the lower surface of the clavicle to the upper edge of the tenth rib at the junction with its cartilage, the resulting thoracic length would approximate the thoracic length index within a few millimeters in every case

It must be evident from the above that if one can establish landmarks on the surface of the chest for giving him the thoracic length, he can determine lung capacity by multiplying this factor by the area expansion

The method for finding this is shown above As a preliminary step I would suggest the following method

1 Estimate area expansion as shown above and express it in square centimeters or square inches

2 Measure the thoracic length from the lower margin of the clavicle at its middle to the upper margin of the tenth rib at its junction with its cartilage, expressing the measurement in centimeters or in inches

3 Multiply the two values thus obtained, and the product will be the approximate lung capacity in cubic centimeters or cubic inches

Applying this method to the case of R B, whose contour is shown in Figure 1, we obtain 3,153 c c, while his lung capacity as measured by the spirometer was 3,100 c c This is a much closer approximation than one would expect usually to find If one can by this method get within 100 or even 200 cubic centimeters of the lung capacity as measured by the spirometer, the value of the method will be demonstrated, as the lung capacity in general varies between 2,900 c c and 5,500 c c

SUMMARY

1 In the calipers (pelvimeter) one possesses an instrument with which he can determine accurately the area expansion in any cross-section of the chest

2 To determine the area expansion, E 1, Measure the dorsoventral and the transverse diameters at expiration and at inspiration 2, calculate the mid-diameter at expiration $\left(\frac{D+T}{2}\right)$, 3, calculate the radial expansion during inflation of the lungs $\left(\alpha = \frac{c+c'}{4}\right)$, 4, multiply together the following three factors π (3 1416) times the radial expansion times the sum of the mid-diameter and the radial expansion $E = \pi \times \left(\frac{D+T}{2} + \alpha\right)$

3 The radial expansion for broad chests is not greater than for deep chests, the average for each being 1 55 cm in the 119 men here discussed

4 To determine the lung capacity, C 1, Estimate area expansion, E, 2, measure thoracic length, L (from the lower edge of the clavicle at its middle to the upper edge of the tenth rib at the junction with its cartilage), 3, multiply these two facts together for the approximate lung capacity $(C = E \times L)$

5 The landmarks for thoracic length may have to be modified as a result of subsequent tests

A CASE OF CORTICAL HEMORRHAGES FOLLOWING SCARLET FEVER *

E E SOUTHARD, M.D
Instructor in Neuropathology, Harvard Medical School
AND
F R SIMS, M.D
Assistant in Neuropathology Harvard Medical School and Second Assistant Physician for Diseases of the Nervous System, Boston City Hospital
BOSTON

[From the Pathological Laboratory of the Boston City Hospital]

The following case of hemiplegia developed in a boy during convalescence from scarlet fever The basis of the cerebral symptoms was a markedly hemorrhagic encephalitis focal in the parietal lobes The reaction is histologically characterized, aside from large areas of hemorrhage and a few superficial or meningeal areas of frank suppuration, by a tremendous proliferation of phagocytes The phagocytes for the most part contain blood corpuscles and dilate or supplant the pial and adventitial meshes In places, the phagocytes occupy the space of lost brain substance which has undergone acute fatty degeneration

CLINICAL HISTORY

G N, an American boy of 5 years, was admitted to the

---

* Read at the Fifty fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology and approved for publication by the Executive Committee Drs. V C. Vaughan Frank B Wynn and Joseph McFarland.

South Department of the Boston City Hospital, Dec 13, 1902, with a few hours' history of vomiting and sore throat

The boy was well developed and nourished and only moderately prostrated The roof of the mouth was slightly reddened The tongue was moist, red and coated, and the papillæ at the tip were somewhat enlarged The throat was congested The tonsils were large and red On both tonsils and uvula was some exudation The heart was slightly irregular in action, and a rough blowing systolic murmur was heard at base and apex, transmitted a short distance into the axilla The face was flushed, with a pale zone about mouth The trunk showed a fresh punctate eruption, which was especially marked in axillæ and groins Other findings were negative or irrelevant

The diagnosis of scarlatina was made and the patient isolated. The disease proceeded as usual, and convalescence was setting in apparently without interruption when, on Jan 14, 1903, while the patient was up in clothes, a slight limp was noted in walking

Once at play the child had a violent contraction of the flexors of the right thigh, which abated after a half minute Early the next morning there were three more attacks, which were terrifying to the child, but painless These night attacks were attended by involuntary passages of urine

January 16 at about 10 30 a m was another attack associated with dull pain in the right knee The attack lasted about five minutes and consisted of regular contractions and relaxations of the flexors of the right leg, at intervals of about ten seconds A second attack occurred about 2 15 p m the same day, in which all the muscles of the right side were affected except those of the face As the symptoms persisted chloral was given, three minutes later the attack ceased Afterward it was found that the right arm was paralyzed and the pain and tactile senses were much impaired There was no loss of consciousness or any further disorder that day

On January 17, the fourth day of the cortical symptoms, the child was wakened at about 9 a m by a violent contraction on the right side of the body, still sparing the face The contractions were relieved with chloral At 4 50 p m the patient was again aroused from sleep by contractions of the right side, this time involving the face. Chloral was again given, with relief After subsidence of the attack the whole right side remained paralyzed. The child now took food with difficulty The sphincters were paralyzed

The notes of the next ten days follow

January 18 —Rectal feeding Sleeps most of time Dull and apathetic Pain sense in whole right side completely lost

January 19 —About 9 30 a m he had another attack involving all muscles of right side, including face Lasted about a minute, unconscious after attack

January 20 —Apparently unconscious all day Does not arouse when rectal feedings are given Sleeps most of the time

January 21 —Somewhat brighter Asked for water and played with toys about an hour Then went to sleep and slept rest of day and all night

January 22 —About 8 30 a m, while sleeping, mouth became closed firmly, and child grew cyanotic and almost pulseless Mouth pried open and color returned Nose found to be occluded with crusts Child emaciating Heart irregular Lungs and abdomen negative

January 23 —Unconscious most of time Emaciation marked Ptosis on right side Right corner of mouth droops

January 26 —Paralysis as before Pain sense on right side lost, diminished on left. Râles on both sides of the back

Gradually failed Râles more numerous Expelled all feedings Died January 28, 7 10 a m

The temperature, which had fallen to normal January 10, less than a month after admission, became 101 degrees F the morning of the 14th and remained elevated till the 20th From the 20th till death the temperature remained normal or was slightly raised

For the observations here recorded we are indebted to Drs T B Cooley and H H Smith, assistant physicians to the South Department of the Boston City Hospital, and to Dr J H McCollom, resident physician to the South Department, we are obliged for kind permission to report the case

SUMMARY OF CLINICAL FINDINGS

The case may be summarized as follows Scarlet fever of moderate severity in a boy of five years Convalescence interrupted about five weeks after onset of fever by cerebral symptoms, fatal two weeks later (seven weeks after admission) The contractions and sensory symptoms began in the right leg and advanced during four days to affect the whole right side, including the face The contractions were sharply defined (at one time alternating regularly with relaxations at intervals of about ten seconds) and limited in duration (a few seconds) Paralysis of the affected limbs ensued During the last week the child was in the main unconscious (masking symptoms on left side)

ANATOMIC FINDINGS

Fairly well developed, poorly nourished white boy, without rigor A very few livid spots on back Scaling on the under surface of toes, on scrotum and under finger nails Skin in general harsh to the touch and over calves feels almost like goose skin Pupils equal, not dilated No edema Extremities symmetrical Very little superficial fat of abdomen

Peritoneal Cavity —Surfaces smooth and dry Appendix crook shaped, retrocecal, points towards spleen, 11 cm long Mesenteric lymph nodes distinct.

Pleural Cavity —Left clear, right shows a few firm adhesions in front Surfaces normal

Pericardial Cavity —Normal

Heart —Weight, 100 gms Measurements Tricuspid valve, 5 5 cm , pulmonary valve, 4 5 cm , mitral valve, 5 5 cm., aortic valve, 4 cm , left ventricle, 1 cm , right ventricle, 2 mm Slight amount of subpericardial fat Myocardium firm, red without fat in teased preparation treated with acetic acid Endocardium, valves and coronaries normal Contents cruor clot and fluid blood

Lungs —Anthracosis slight Postmortem congestion on both sides, most marked on the right Peribronchial lymph nodes normal Bronchi normal

Spleen —Weight, 30 gms Capsule pale bluish, of usual tenseness Substance brownish red, not pulpy Malpighian bodies unusually distinct Trabeculæ evident

Gastrointestinal Tract —Normal Pancreas —Normal

Liver —Weight, 560 gms Nut brown, with a somewhat accentuated mottling Areas central in the lobules, somewhat darker than the peripheral areas Consistence normal or slightly decreased

Gall Bladder —Normal

Kidneys —Weight, 110 gms Strip well Stellate veins of cortex injected Cortical substance translucent reddish gray Pyramids darker than cortex, with well marked radial injection Fresh specimen shows no fat when treated with acetic acid. Glomeruli seen in sand granule form Ureters normal.

Adrenals —Unaltered Bladder and Genitalia —Normal

Aorta —Normal

Brain —Weight, 1,275 gms Dura of normal thickness and tenseness, not adherent to calvarium Pia over vertex and occiput lifted by clear fluid, which leaks away in amount estimated at from 30 to 40 c c The parietal lobes on both sides of the great fissure show a number of coin sized, reddish areas affecting an area which could be covered by the palm of the hand, circular or oval in shape, with well marked, finely irregular borders, with a very few fine points of injection, disconnected from the main area Shade of red was usually pink, but on the right side the areas were darker and the tissue about the veins in the sulci had assumed a slightly greenish tint On section these areas proved to be the external aspect of almost exclusively intracortical hemorrhages, varying in appearance from groups of puncta cruenta to soft, grumous, red brown lesions extending in some places into the white matter

The finely irregular border was observed throughout. The pial vessels seemed intact. There was no lesion of pia beyond the slight discoloration on the right side mentioned above Ventricles showed a normal amount of fluid Rest of encephalon showed no lesion

Spinal Cord —No lesion evident to the naked eye

The autopsy was performed at the South Department, Boston City Hospital, by one of us (E E S) during the pathologic service of Dr F B Mallory, to whom we are indebted for suggestions

SUMMARY OF ANATOMIC FINDINGS

Desquamation of skin after scarlatina Organs and tissues in the main showed little gross evidence of lesion Fresh and pigmented hemorrhagic lesions in the cortex of both parietal lobes, with edema of overlying pia mater

MICROSCOPIC FINDINGS

Cultures from both lungs, the liver and the spleen showed abundant growths of the *Staphylococcus pyogenes aureus* The lung cultures were pure The liver showed beside aureus, a bacillus of the colon group which was not farther worked out The spleen showed beside aureus, a few colonies of streptococcus Cultures from the meninges and from the hemorrhagic areas beneath the pia mater remained sterile.

The histologic examination of the organs of the trunk was in the main negative A section from right lung in the area of most marked postmortem congestion showed a cellular exudate of focal character, rich in polynuclear leucocytes and in bacteria both inside and outside the cells These bacteria were largely staphylococci but there were a few rather long chains of streptococcus like forms, and some short, slender bacilli The organs were in the main well preserved It is probable that the case can be interpreted as one of scarlet fever with a terminal aureus septicemia, complicated with or derived from a bronchopneumonia

Pieces from various portions of the brain (both at the foci of hemorrhage and at a distance) and from the cord, were fixed and stained for general histologic work, for bacteria, for neuroglia, and for fat

Numerous pieces were examined which showed no evidence of a lesion which could be regarded at first sight as infectious Consider, for example, the data of the following description of findings in the lesion of the left parietal lobe.

(a) The meshes of the pia mater cerebri and of the tunica adventitia of the majority of the short medullary arteries of the cortical system are filled with countless phagocytes In places beneath the pia adjacent to the larger foci of hemorrhage the phagocytes fill several oil immersion fields with here and there a stray bundle of connective tissue fibers About some of the arteries there has occurred loss of substance and replacement with fluid containing phagocytes and the stromata of blood corpuscles The phagocytes are large, well rounded cells of two to three or more times the cubical capacity of adventitial cells lying in situ The nuclei of the phagocytes are in the healthy cell, constantly oval and vesicular with a more or less prominent central nucleolus The perfectly oval nuclei are likely to be slightly eccentric in the cell When the cells had ingested blood corpuscles or (more rarely) other cells of the blood series, the intrinsic nuclei showed a slight contraction and apparent condensation of chromatin The nuclear membrane may fold in the major axis In the highly vacuolate examples or in cells stuffed with blood corpuscles, the nuclei are applied closely to one, arc of the cell contour, and are crescent shaped or cap shaped The elongate character of the nucleus is preserved to a late stage in the series of changes and is observed even where the cell body was breaking up There are some cells apparently of this series with round, deeply stained, slightly ragged nuclei and a slight rim of protoplasm, which may form the regressive stage of phagocytes which for some reason have not taken up inclusions. But in the majority of cases the regressive changes in the nuclei and the fragmentation of the cell bodies ensue on the stuffing and vacuolation of the cell bodies It is impossible to say whether chemical or mechanical changes play the higher part here, descriptively speaking, the mechanical factors would seem sufficient to bring about the destruction of these cells, which are nourished alone by a fluid containing many kinds of detritus Cells of this series are often caught in mitosis and in this condition are, as a rule, found just outside the muscularis of an artery

The nerve cells near the phagocyte masses are extensively modified, mainly by edema There are many collections of fatty detritus demonstrable by the Marchi method and by Scharlach R. in frozen sections Many of the phagocytic cells have taken up fatty detritus in rounded masses, forming a positive picture of the vacuoles seen in general stains Some of the larger (Betz) cells of the region have undergone another type of degeneration By the Nissl stain this type of degeneration is not demonstrable, but by neuroglia and fibrin stains a characteristic picture is obtained of cells variously shrunken and of ragged or punched out but sharp contour, in which the nucleus is opaque and the cell body contains numerous deep blue dots or rounded masses of a mainly peripheral distribution These dots are smaller and less angular than the normal tigroid bodies, but of somewhat the same distribution, sparing the shrunken remnant of axis cylinder They run out as far as the dendrites can be traced and seem to impart to the dendrites a pliable character, whence they readily stay in bent positions somewhat like glia fibrillæ Such cells are usually found remote from normal tissue and are, as a rule, surrounded by phagocytes of the usual type as described above The phagocytes occasionally occupied niches in the periphery of these cells, but we should be unwilling to regard the condition as a true or essential neuronophagia Occasionally, beside such a dotted cell, a true satellite cell is found, such as accompanies many normal nerve cells These cells also are to all appearance inactive The process must be regarded as peculiar, but of no great significance in point of frequency The more frequent regressive change in the nerve cells in such conditions is probably edema and fragmentation with fatty degeneration and more or less rapid solution

Near the phagocytic areas there is but slight evidence of change in the glia cells A few show enlargement of the cell body (the nuclei here is as a rule spheroidal), but there is no evidence of mitosis or of new fibril formation

Aside from the adventitial changes related with the production of the phagocytic cells, no important alteration is notable in the vessels

(b) In some regions, notably in the uppermost portion of the right parietal lobe opposite the arachnoidal villi, the lesions described under (a) are complicated with a frank suppuration in the pia and attached villous system In the lymphatics and free in the meshes of the fibrous envelopes of the arachnoidal villi are dense collections of polynuclear leucocytes enclosed in a fine, even mesh of fibrin The lymphatic clefts in the pia contain granular coagulum and in their walls are fairly numerous polynuclear leucocytes In the looser tissues beyond and especially internal to these clefts are numerous phagocytes of the usual type, some of them contain polynuclear leucocytes The tissues beneath the pia consist of deep masses of phagocytic cells, with here and there vessels lying almost free. A short distance inward there are few polynuclear leucocytes to be seen, and the phagocytes contain fat or blood globules exclusively

(c) By the Marchi method a rather selective degeneration is demonstrable in both upper motor systems, more marked in the system arising from the left hemisphere In the cord there is an axonal degeneration of the anterior horn cells (Nissl method) and a corresponding selective fatty change in many of the anterior roots There are also other diffuse isolated fiber degenerations less easy to reconcile with the systematic changes No myelin degenerations are demonstrable by the Weigert method

SUMMARY OF MICROSCOPIC FINDINGS

The findings microscopically were Early bronchopneumonia, due to the *Staphylococcus pyogenes aureus* Purulent infiltration of foci in the parietal pia mater and overlying arachnoidal villi Hemorrhages in the cortex and extensive development of cells phagocytic for polynuclear leucocytes, blood corpuscles and fatty detritus, in meshes of pia and in adventitia of short arteries of the cortical system Phagocytosis, associated with solution and fatty change of neighboring nerve tissues Peculiar dot-like necrosis in some nerve cells, which assume the glia stain Fatty changes in associated motor systems and early changes (axonal degeneration) in the lower motor systems

REMARKS

The conception of encephalitis has suffered from a dearth of adequate descriptive work The systematic treatment has, therefore, not kept pace with that of inflammation in other tissues For example, it was possible to say in 1886 that we can as yet present no unitary picture of processes which culminate in brain softening, if we except those which result from vascular changes [1] Yet in 1904, in the latest systematic treatise on encephalitis, we hear that recent distinctions of encephalitis into various forms are erroneous, and that all these phenomena can be produced by any appropriate inflammatory agents, among which are numbered the organisms of meningitis and of influenza, embolism, aseptic trauma, corrosive substances and heat [2] It is probable, however, that further study will make clear a difference in the effects of members of this series of agents

There are several characteristics of the lesion produced in the brain by bacteria or their toxins which serve to obscure the issue by drawing attention, on the one hand, to the vascular system, and, on the other hand, to the neuroglia Thus a recent triadic division[3] of encephalitis into, 1, purulent, 2, hemorrhagic, 3, hyperplastic, is based on the predominance in the histologic picture of suppuration, diapedesis and hemorrhage, or secondary glia-cell changes It is, however, probable that all these pictures may be produced by identical agents The omnipresence of the meningeal and adventitial phagocyte has contributed toward a false unification of the pictures of bacterial and those of mechanical origin

Herein we have sought to bring out the predominance of hemorrhage and phagocytosis with destruction of cortical tissue, the focal effect of meningeal suppuration in a case of subinfection with the aureus during convalescence from scarlet fever The case is one of cortical hemiplegia caught in process, and brings out the now frequently exemplified inflammatory origin of this disease

Venereal Diseases and the General Practitioner—Professor Neisser of Breslau has recently published an appeal to the general practitioner to perfect himself in the diagnosis and treatment of venereal diseases The idea that a specialist is required for them is absurd, he thinks Venereal diseases, more than all others, belong in the domain of general practice, and medical students should be trained to differentiate and treat them If every medical graduate were trained in the early recognition and means of aborting these affections, this would prove the most important forward step in the prophylaxis of venereal disease Neisser's article was published in the *Medicinische Woch* v No 15

THE STARVATION OPERATION FOR MALIGNANCY IN THE EXTERNAL CAROTID AREA

ITS FAILURES AND SUCCESSES *

ROBERT H M DAWBARN, M D
NEW YORK CITY

The present status of the starvation plan of treating malignant growths in certain regions adapted to it anatomically may, with entire truth, be said to be that of an untried plan, to all intents, and the chief reason for the present paper is to call attention to this fact, and to ask for it the justice of a thorough study, to corroborate or to overturn the views of its originator, as the results may warrant

That the method is still practically untried, so far as the great body of the profession is concerned, has two reasons, both quite obvious The first of these is the fact that, except in my Gross prize essay, I have never yet written on the subject Indeed, to-day's paper may accurately be said to be the first public presentation of this subject that I have made Repeated illnesses and the rigorous demands of professional work to the limit of my strength may, I hope, be considered a sufficient explanation The subject is to me so fascinating that I would gladly devote to it further years of my time I ask those who have tried this plan, or who may do so hereafter, to send me their data, whether good or bad in outcome These will be published, when in sufficient amount to be worth while, and meantime, by means of articles in various journals, let us hope attention will be drawn to the plan

It has been said that two reasons exist for the lack of a reasonably fair trial The second one is the obvious discouragement of the surgeons of my own surgical society, that of New York City, for of late none of them has, at least to my knowledge, been using it The explanation is quite plain Reference to the detailed records in the Gross prize essay will show that but ten of our members have tried the plan, and in each instance where the final result was obtained, the case was one of cancer and not sarcoma This is quite a remarkable fact (of course, merely the result of chance) and an unfortunate one, for in all these cases there was only a shrinkage of varying extent from little to much, for a brief period, not always stated but probably always inside a year, for these people were invariably cachectic and far advanced in cancer before being subjected to this, a last chance Now, since in none of these was the disease stayed very long in its advance, apparently these surgeons and others, hearing of their results, have assumed that in sarcoma the period of life gained would be equally small, but have not, however, tested this assumption practically Let us hope that the truth may soon be known, and at the hands of many operators the world over The method at least deserves this

By reference to my own detailed cases anyone will observe how much more favorable are the results with sarcomata than with carcinomata, and the minute anatomy of either of these tumors readily explains why this should be so

A priori Cancer spreads chiefly through its lymphatics, and control of the arteries does not necessarily affect the lymph channels very radically Sarcoma, on the other hand, spreads chiefly through and along its vascular system, and shutting off most of its blood therefore directly opposes the spread of the sarcomatous growth.

---

* Read at the Fifty fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee Drs DeForest Willard Charles A Powers and J F Moore

In several instances I have recorded and shown patients with starved and shrunken sarcomatous tumors, long past the three-year period, which Volkmann suggested as one after which with some degree of certainty we may claim a cure. Two cases are specially striking on the published list—both subperiosteal round-celled sarcomata of the lower jaw, a variety and a situation which Butlin, certainly an able authority, considers hopeless, however handled, and whether excised or not.

But for those who purpose repeating my own work, attention should be called to an essential step in the technic in lower-jaw cases. This is, in addition to the usual double excision of the entire external carotid (for safety done at different dates), to tie the inferior dental artery and its mylohyoid branch, just as this artery is about to enter the inferior dental canal. Also, to cut out an inch or more of the inferior dental nerve, thereby making sure that if the tumor should at some future time resume growth, this nerve being thus treated, of course on both sides of the neck, such growth would be and remain comparatively painless. It does not add more than a few minutes to the length of the operation after completing the external carotid excision, to deepen the wound toward its front, behind the ramus, until the inferior dental vessels are exposed, forcibly lifting the ramus by a sharp retractor, which also holds it immobile during the necessary dissection beneath it, is a step which aids the ease of work. In one of my reported cases I trephined the ramus to come down on the vessels and nerve, but in the other instance found it easy to find them as just detailed and without any trephining.

The reason it seems wise to control the inferior dental vessels in the lower-jaw cases is that this branch of the internal maxillary anastomoses quite freely, if indirectly, with the internal carotid, at higher points along its course.

Here should be mentioned the fact that orbital growths, or growths likely to be reached by any branches of the internal carotid, are plainly beyond hope by the starvation plan, and in fairness this point should be considered, otherwise this new plan would be attempted, as, indeed, I know of instances, in entirely hopeless fields. In a general way the lower in the external carotid area is the growth the greater are the prospects of its success. Of the twenty-nine ways in which the external carotid system can anastomose with outside systems, the internal carotid furnishes twenty-one, the subclavian seven, the innominate one. Our chief enemy, then, is the internal carotid.

The main channels within the external carotid system for such communication are three, viz., the terminal two, i. e., internal maxillary and superficial temporal, and the occipital. The former two, starting in the substance of the parotid gland, meet and mingle with the deep or internal carotid circulation in seventeen ways, the occipital with the subclavian in five ways. Since these three branches of the external carotids account then for 22 out of a total of 29 outside anastomoses, it is plain that they are our chief sources of danger and should receive our particular care, also that it would be almost impossible to starve a tumor of the parotid gland area. If Wyeth's suggestion of supplementing vascular excision by some plastic injection is to be tried these three are the branches which require it at our hands. The normal flesh however, requires *some* blood in order to live and with these three branches plugged shutting off twenty-two of the twenty-nine possible anastomoses, I have seen, in a few cases, slight sloughing follow—as an edge of the ear, or an inch or so of the skin of the face. The cancer, if soft, will regularly slough in such circumstances, which is, of course, desirable, and it should be trimmed away where dead to avoid a foul odor, septic absorption, etc.

The report of the few cases where injection has been extensively tried is not very satisfactory. However, this, like the vascular excision, is a wholly new field, and early mistakes were made as to material used, amounts injected, etc., all of which have been fully and honestly reported in the essay. It seems to me, however, that it is so advisable to cut off by this simple and quick way the seventeen undesirable anastomoses coming from the two terminal branches, that the weight of argument is greatly in favor of it. Generally, therefore, I inject the distal end of the external carotid where it enters the parotid gland, thus plugging and rendering harmless this nest of enemies. And since I have ceased to plug the occipital also, I have seen no sloughing of normal flesh. Depending on the location of the growth, I now plug either the occipital or the external carotid end, but not both. It has been determined in various ways that forty-five minims of the fluid is, in the adult, entirely safe, but much more, apparently, would not always be so. This, too, is the proper dose for the occipital, when that is chosen to be obstructed. Because it is so small a vessel, it simplifies injecting the occipital to tie the external carotid just beyond where it is given off, and then to inject this carotid closely proximal to the occipital, which thereon, of course, receives the heated fluid. The best material proves to be a mixture of hard white paraffin one part, white vaselin, nine parts. This hardens at 108 F., too high a thermal point to make it likely that any subsequent fever could melt it out, and is introduced at 120 F. With moderate dexterity and speed the injection can be completed, at this heat, before the paraffin solidifies, becoming opaque and white.

Whoever contemplates trying the injection, of course supplemental to excision of the external carotid, must remember never to take this step until he has first made absolutely certain that there is a regular bifurcation of the common into the external and internal carotids, for the anatomic arrangement which is the rule in the dog also constitutes the most frequent anomaly in man, namely, that the *internal* carotid, on its way to the brain, gives off branch after branch, which practically correspond in order and distribution with those normally arising from the *external* carotid, which last artery is, in such a case, either non-existent or is insignificant in size.

If the operator, taking a normal bifurcation of the common carotid for granted, proceeds to operate as usual and finally to excise what he mistakenly supposes to be the external carotid, no harm is done except that he has substituted for the trifling risk of external carotid excision (certainly well below 5 per cent.) the mortality of internal carotid ligation, which Wyeth figures at 40 per cent. But if the operator proceeds to inject the upper end of his artery, supposing he is about to plug thereby the internal maxillary and superficial temporal, he will cause instant death by plugging, instead the circle of Willis, and the vessels of the respiratory area of the brain.

This peril, like many in surgery, ceases to be a danger as soon as it is recognized. It will be plain that the ordinary test, whereby the operator makes sure that he has the external carotid under his finger, namely, observing whether controlling it stops the pulse over the zygoma, and where the facial crosses the body of the lower jaw, is deceptive, supposing the commonest anomaly, just mentioned, to exist For the pressure on the internal carotid, giving off later the superficial temporal, facial, and the rest, will, of course, stop their flow However, no mistake as to the carotids can be made, providing the surgeon, before proceeding further, takes a minute for dissection, enough to convince himself that the common carotid divides in the usual way, or does not so divide Hence it is well to begin this operation by exposure of the common carotid, and thence proceed upward, rather than to come down on the external carotid branches as the first step, and commence tying them off

It is well to throw a ligature as soon as possible about the external carotid close to its origin, thus having it under instant control, but it will be found best not to tie it early, for then its branches, bloodless and reduced to mere threads, are with more difficulty found

When finally the ligature is tightened and the vessel divided, its distal end should be made to take a dive, so to speak, beneath the twelfth nerve, the stylohyoid and the posterior belly of the digastric muscles, and reappearing above these structures its stump can with greater ease be followed to the parotid gland, and here injected if thought best

When first I began to study this field of work, I carefully preserved all veins and venous plexuses, at the cost often of much vexatious delay in dissection This was only one of various mistakes which later experience corrected, but which can not be discussed in a paper of this length My idea was that greater anemia would result if the veins and venules were left to carry off by force of respiratory chest-action any remaining blood in the tumor, and temporarily this is a fact As Dr Bristow pointed out, however, when a long time later possibly remaining anastomoses are endeavoring to form new arterial supplies, they will have more difficulty in so doing if there is an absence of veins to carry away such blood Hence the plan now thought best contemplates the simpler step of sacrificing all blood vessels as radically as possible, whether arterial or venous

One further point in technic, too important to be omitted, is to do the first of the two external carotid excisions always on the sound or less diseased side first This rule, the reverse of what one would naturally do, is based on painful experience If the surgeon operated first on the side primarily controlling the malignancy, often during the regular period of waiting for recuperation between operations (two to three weeks, commonly), there will be a noticeable shrinkage of the mass This starts a most unwise belief in the patient's mind that he is now on the highroad to recovery, and that there is no real need for operating on the other side of his neck, to which step he looks forward with dread He shares a common belief that surgeons cut just for the pure joy of cutting, and here is, he thinks, a peculiarly atrocious instance in point His cancer has evidently begun to go away, and why should not he take the hint and do likewise? He does, and either never returns, or does so too late from weakness due to a rapid recurrence of growth activity to render justifiable any further intervention whatever

If, however, the operation is first performed on the carotid of the sound side, no shrinkage, of course results to deceive him Realizing that the starvation plan with its duplicate operations is his only hope, he abides by his surgeon's advice, and at the proper time again submits to the knife And now, though very likely not permanent, the shrinkage will, at least as a rule in sarcoma, be of such considerable duration as to justify what has been done

If permitted on one side only, an external carotid excision is simply a waste of time, and this is equally true as to even a ligation of both without vascular excision

This refers, of course, to control of malignancy But on the contrary, ligation of both external carotids renders wonderfully safe many face and mouth operations, otherwise perilous from shock due to hemorrhage, and in my opinion this step will soon come into regular employment before such otherwise bloody work Curiously enough, Butlin (and most other authorities on malignancy) in no instance advises ligation before the usual extirpation of a tumor Apparently, he still entertains the old fear as to hemorrhage following ligation of the external carotid—due to the lack of an internal clot here, because of the numerous branches—a fear wholly groundless This ligation, in experienced hands, has practically no mortality Indeed, the entire extirpation of these arteries, when not complicated by masses of diseased and adherent lymph nodes, is surprisingly safe It is also the testimony, I believe, of all those who have tried it, that carotid excision is not especially difficult

CONCLUSIONS

In conclusion, I think there can be little dissent from the following propositions

1 The starvation plan, in sarcoma, has in some instances effected permanent cures—that is, shrinkages—not otherwise possible, but it is not asserted that such may always be expected Since, however, this plan is admittedly a *dernier ressort*, any percentage, however small, of such permanent checking of malignancy is a victory not otherwise possible

2 In both sarcoma and carcinoma, the knowledge on the part of the patient that by this method he has one more chance, though all other plans have failed, and the growth be beyond excision, restores his courage and cheerfulness and puts aside the imminence of despair As a surgeon has phrased it, we substitute in such a case, instead of the certainty of death, once more the uncertainty of life

3 Even in cancers, we can be reasonably sure of a few weeks longer life, sometimes up to a year, otherwise impossible when other plans have failed At first thought, if it should prove but a month or two of gain, we might question whether it be worth while But in my experience patients are grateful for even a short respite, and the decision is for them to make, not for us, as to whether it is worth while Given a man of wide business interests, for example, a few weeks longer in which to stave off the inevitable, may mean everything to him in the orderly winding up of his affairs

4 Again and again I have found the resultant shrinkage of tumors to give promptly the greatest relief to suffering, and permit the patient to cut down or stop the large doses of morphin formerly demanded This important point has also been observed by other operators

5 Given a growth of the region under discussion, excessively vascular perhaps, and too large to be cut out, in several recorded instances (one of them, the first of

ill, nine years ago) this operation has so shrunken the mass and so deprived it of blood as to permit, after a short time, an extirpation of the tumor, partial or complete, not otherwise possible

Within the past month a letter has been received from Dr J Chalmers DaCosta covering exactly this point I quote from it by permission A patient from Texas with carcinoma of the face had been seen by two distinguished Philadelphia surgeons The growth was then too extensive to be excised, and hence operation was declined by them Dr DaCosta performed the carotid excision on both sides last winter "The subsequent shrinkage was gradual, but certain," he writes, "masses of fibrous tissue were developed about it' A few weeks later he was able to perform an apparently complete removal of this cancer His concluding words express the idea under discussion, and which represents it may be, as practical a value to us as any in this starvation work, namely "This use of the operation, bringing, as in this instance it did, an at first inoperable growth into the range of operation, seems to me a very important and interesting phase of the matter"

DISCUSSION

Dr. A T Bristow, Brooklyn, N Y—I have performed this operation eleven times on six patients, the twelfth operation being done by my assistant, Dr Campbell In only one of these cases was the disease sarcoma, and in this case the patient died a short time after the second operation, therefore, I can not speak from experience of the curative value of the operation in this class of cases All the remaining cases were carcinomata, four occurring in the upper jaw, springing from the antrum One case was an epithelioma of the lip which had involved the lower jaw and was inoperable In all these cases I noticed that the pain of which the patients complained ceased after operation Shrinkage of the tumor also took place, and there was much diminution in the discharge from the cancerous mass One of my cases was alive at the end of a year Another I kept under observation for four months The disease at this time was stationary Judging from my own experience of two sudden deaths occurring one shortly after the operation and one in a case not here included, but done by Dr Campbell at St John's Hospital, I am obliged to come to the conclusion that there is a risk attached to this procedure which is out of proportion to the dissection We constantly, particularly in cases of tubercular adenitis, make dissections of the neck which are far wider and more extensive, yet there is no mortality in these cases All my cases suffered from respiratory failure when the stump of the vessel was made to take the dive beneath the hypoglossal nerve They all recovered, but the case which my colleague lost died at this point in the operation from complete failure of respiration. I am inclined to think that interferencee with the superior laryngeal by the traction may bring about pneumogastric inhibition The operation is sometimes easy, sometimes very difficult, and, of course, should only be resorted to in cases inoperable by ordinary methods

Dr. Dawbarn—I am sorry Dr DaCosta is not here, as he was, at my request, the first surgeon to practice this method. As Dr Bristow has said, and I agree, there is a sudden and complete cessation of excessive pain after external carotid excisions for malignancy, and in many cases the patients will be very thankful for a few weeks more of life, and without pain, in which to settle up his affairs I have referred in my paper to one personal case where such a decided shrinkage took place that an operation was made possible As to the question of mortality, although I have done the operation about 60 times, I find it very difficult to estimate mortality We must remember that this operation is always done as a last resort in cachectic subjects, often with masses of diseased and adherent glands over the carotids, and it is a choice between this attempt and a coffin Simple, uncomplicated ligation of both external carotids may be said to be devoid of mortality, certainly it is well below 1 per cent in skilled hands, and excision of both these arteries in non complicated cases, with a fair degree of vital power remaining, should not, with skillful work, result in more than 5 per cent of mortality

THE INFLUENCE OF THE ADIPOSE TISSUE WITH REGARD TO THE PATHOLOGY OF THE KNEE JOINT *

A HOFFA, M D

BERLIN

Disturbances of the knee joint caused by the adipose tissue have already been described in some cases by Johannes Muller as lipoma arborescens, and by Konig as lipoma solitarium The former disease is determined by the exuberant growth of fat villi, sometimes to such an extent that they fill up the joint and cause an expansion of the capsule Schuchardt was the first to show by his microsopic researches that these conditions had nothing to do with tuberculosis of the knee joint

The lipoma arborescens is no real tumor like the lipoma solitarium of Konig, which varies from the size of a cherry to that of a walnut and is generally situated on the median side of the joint, with a pedicle reaching into the joint itself Konig thinks these tumors originate in the subsynovial fat tissue, and compares them in this respect to the lipoma subperitoneal They have been removed by Konig, Volkmann and others, and the supposed to result from some trauma of the synovial membrane effecting a slit through which the parasynovial and retrosynovial adipose tissue escape into the joint. These tumors are certainly not all real tumors, and I would rather class them as an inflammatory fibrous hyperplasia of the articular adipose tissue, which, according to my experience, is an important factor in causing disturbances of the knee joint I first came across this hyperplasia of the fat tissue some years ago on incising a knee joint for the sake of extirpating the detached meniscus, as I thought, which, however, was intact, and subsequently a great many similar cases were diagnosed by me beforehand showing this hyperplasia of the fat tissue beneath the ligamentum patellæ quite typical

The sound knee joint presents the following anatomic conditions Under the ligamentum patellæ the synovial membrane shows two plicæ alares and a plica synovialis patellaris The former consist of fat tissue with a coating from the synovialis, which stretches from the front margin of the tibia like a fat lobule into the joint, and even sideways beyond the ligamentum patellæ From the central summit of the plica alaris originates the plica synovialis, which is composed of fibrous fat tissue inserted at the fossa intercondyloidæ A sagittal section of the knee joint shows this fatty tissue situated like a wedge between the patella, femur and tibia. While the upper part adheres to the ligamentum patellæ, the lower is separated from it by the intervening bursa infrapatellaris profunda and joins the meniscus, also being connected to the periosteum of the front part of the tibia I have dissected a large number of normal knee joints and always found the above conditions from early childhood upward, the growth of the adipose tissue varying individually, sometimes cachectic individuals showing a larger growth than fat persons

A section of this fat tissue shows an extensive delicate network of fibrous strings interspersed with fat lobules, the surface being covered with a single layer of endothelial cells and small villi, increasing in number from the central parts toward the surface These villi consist of a delicate fibrous tissue covered with endothelial cells showing slight vascularity

---

* Read at the Fifty fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy and approved for publication by the Executive Committee Drs. DeForest Willard, Charles A. Powers and J E Moore.

This normal adipose tissue is liable to grow and to produce a hyperplasia inflammatoria, even after slight trauma of the knee joint occurring chronically, and can then be felt as a pretty hard mass of fat on both sides of the ligamentum patellæ, similar to a lipoma These growths, I found differ widely from the normal adipose tissue as regards size, color and solidity

The growths that I have removed have often been larger than an egg, and beside the normal color, they show a reddish-yellow tinge, indicating hemorrhages I have also come across regular blood clots enclosing the above-mentioned villi when the operation was performed immediately after severe attacks of pain The adipose tissue is much more solid than you usually find it on account of the strong fibrous tissue A section shows very markedly a network of these solid strings enclosing the enlarged lumina of blood vessels My assistant, Dr I A Becker, has described the histologic details of these cases, and I shall only give you a short summary of our investigations

In the beginning of the process, beside centers of cellular infiltration, there are found fibrous tissue cells, leucocytes and perivascular cells, with endothelial cells winding along the surface of the increasing number of villi The blood vessels are filled and extravasation into the surrounding tissue has taken place

Later on you see the inflammatory process marked by granulation cells, which gradually take the place of the fat tissue, forming fibrous strings and showing the residues of hemorrhage, sometimes with pigment cells and even extensive necrosis, so that after a time the endothelial cells are joined immediately to the fibrous tissue without any intervening fat

This process is characteristic of an inflammatory hyperplasia of the adipose tissue interspersed with strong fibrous strings, and is generally caused by some trauma, either a fall on the knee or some other hurt, such as a sudden jerk, etc The hemorrhage must be considered as primary, followed by inflammation and exuberant growth of the villi, which are liable to be crushed between the tibia and femur, and this strangulation of the villi regularly makes the patient consult the doctor, showing symptoms quite similar to those of floating bodies of the joint

The pain is felt quite suddenly on the median side of the joint, the knee can either not be bent or the patient is not able to stretch it Hemorrhage into the joint itself may have taken place, but this is not generally the case After a time an atrophy of the quadriceps muscle is more or less developed, and there is a typical swelling of the knee joint on both sides of the patella, especially in its lower part, where the ligamentum patellæ insert, which is often raised by this growth, showing pseudofluctuation The patient should be examined standing and both knees compared There is no discharge into the joint, whose power of motion is generally unimpaired, only presenting a slight crepitation, very different from that of arthritis

DIAGNOSIS

The diagnosis of these cases is not difficult, and they can be separated from the cases of derangement interne, of separation of the meniscus or of floating bodies Separation of the meniscus causes the patient to localize the pain exactly within the joint cleft, floating bodies may be determined by Rontgen rays, while in our cases there is perhaps just a slight indication of a shadow within the otherwise clear space between patella, femur and tibia In all my twenty-one cases which I have observed within the last year and a half, except the first, where a separation of the meniscus was diagnosed, I was able to confirm the diagnosis made beforehand by a subsequent operation

These observations have also been made by other surgeons, but mostly accidentally while operating for floating bodies or other disturbances of the knee joint Thus Konig, in the festive paper for the celebration of v Esmarch's eightieth birthday, mentions having cured an officer by extirpating one of these villi

Similar cases have been published by Herhold and Lauenstein, the latter's case being complicated by a fracture of the patella also Borner, Martens and the American surgeons, Painter, Goldthwait and Ewing, have published observations similar to these

TREATMENT

Operations on these cases should be undertaken after the other methods, such as massage, compression, etc have been used without success, by an incision on the median side of the patella Of course, asepsis is a *conditio sine qua non,* and I have always followed Konig's "golden rule," to avoid bringing my fingers into contact with the joint and only to work with as few sterilized instruments as possible

The result is generally very satisfactory, as the disturbance caused by these growths is removed, together with their extirpation, and the operation, carried out under the necessary aseptic conditions, is without danger

For the first twenty-four hours after the operation I mostly use a small sterilized gauze strip as a drain to the joint After eight days the sutures are removed and the patients may walk about, movements and massage being soon applied The full use of the leg is secured in from six to eight weeks

I can certainly recommend this operation, especially in such cases where other appliances have been resorted to in vain, and I have been able to remove very severe symptoms and definitely heal my patients by this method

TWINE IN LIEU OF THE ELASTIC LIGATURE FOR PERFORMING GASTROENTEROSTOMY *

J W DRAPER MAURY, M.D
NEW YORK CITY

During the past winter two innovations have been practiced at the surgical laboratory of Columbia University They consisted in the carrying out of suggestions[1] made in a previous communication from the laboratory, to-wit First, that gastroenterostomy might be successfully practiced with the use of a triangular instead of a quadrangular stitch, and second, that the material for inserting the stitch might be twine instead of the elastic ligature

Weir objected to the technic as originally devised by

---

* Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee Drs DeForest Willard, Charles A Powers and J E Moore

[1] As has before been stated the original impetus for this investigation as in the case of so many others, was furnished by Dr Robert F Weir I take this opportunity to thank him for many helpful suggestions and for unfailing encouragement

McGraw, because he feared that the patency of the opening might be affected by bridges of tissue establishing themselves between the margins of the slit He said that if a method could be found by which the elastic could be made to "punch out," it would seem to be ideal Two students of the Columbia Medical School finally perfected the stitch They were Messrs Kussler and Thomas, and they should receive full credit for their important part of the work They demonstrated that if the elastic ligature is placed in the form of two juxtaposed squares,- it will with certainty punch out as large an opening as is embraced by the elastic They operated on a pig, and produced a very perfect specimen of enteroenterostomy, as shown in Figure 1 This specimen was removed after the pig had lived for six months

It having been shown in a great number of trials on dogs that this stitch would invariably produce a large and commodious opening—these specimens having been demonstrated before the American Society of Clinical Surgery, at its recent meeting in New York—this part of the work was considered completed

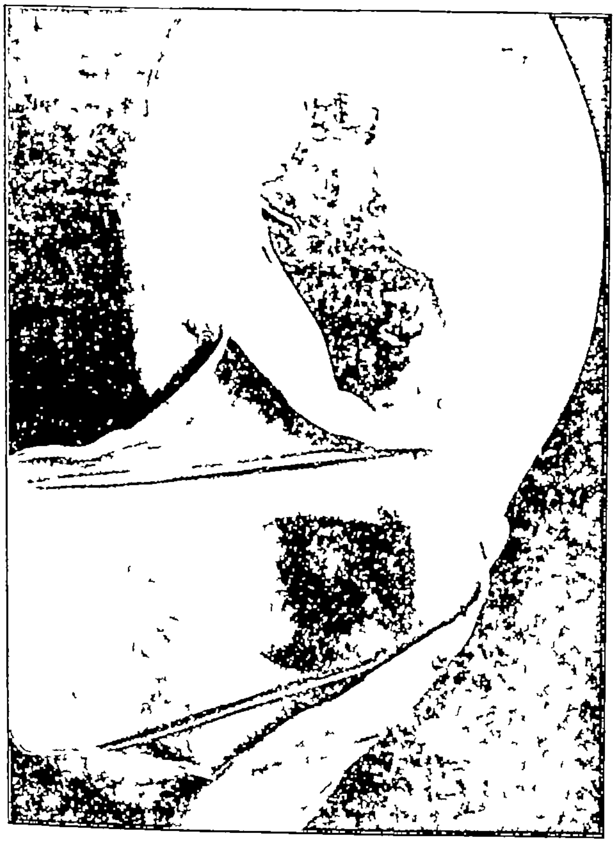

Fig 1—Enteroenterostomy in pig Elastic quadrangular stitch

Three months ago cord was substituted for the elastic ligature, and the triangular stitch was used in place of the square Thirteen dogs were operated on, the stomachs of all of which are on exhibition in the scientific exhibit The series is a small one, but it is consecutive

Photographs of three of these specimens, taken by Dr Edward Leaming, instructor in photography at Columbia University, are herewith presented

Figure 2 shows an enteroenterostomy Figures 3 and 4 represent gastroenterostomy Figures 2 3 and 4 depict specimens from dogs, Figure 1, as before stated, being from a pig The gut of this animal more nearly resembles that of man and affords, therefore, more satisfactory experimental results

The stitch has been inserted in a simple circle, as in McGraw's technic, string, however, being substituted for elastic In the single specimen obtained, a satisfactory,-although not a wide opening was made The advantage of the triangular stitch appears to be that the zone of necrosis can be carried as far from the main line of pressure as may be desired, in other words, the principle of the triangular stitch differs from that of the single stitch method, in that the operator using it has complete control over the lateral size of the opening, as well as over its longitudinal dimensions Thus the triangular stitch enables one to increase the size of the two dimensions, whereas the width of the McGraw is a constant factor not subject to change

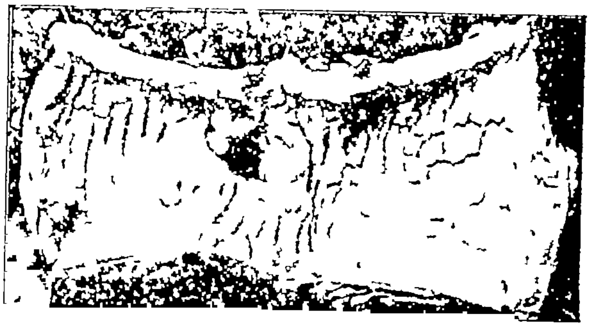

Fig 2—Enteroenterostomy in dog Twine triangular stitch.

There has been a doubt in the minds of a great many surgeons as to whether the McGraw elastic will cut through Enough operations on dogs have been performed at the surgical laboratory to confirm Dr McGraw's contention, if, indeed, this were necessary, that, properly inserted, the elastic will always cut through

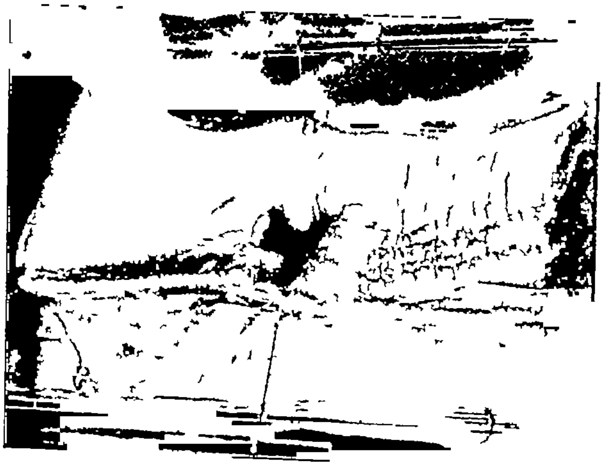

Fig 3—Gastroenterostomy in dog Twine triangular stitch. Shows mucosa of gut and serosa of stomach

But if it can be shown, as it appears to have been by these thirteen consecutive successes of the twine triangular ligature that twine will cut through as efficaciously as elastic, its advantages over this material can not be overestimated In the first place, a bit of twine is always at hand In the second place—and this is most important—it does not deteriorate, as does the elastic with age Even if the elastics be obtained directly from the manufacturer at Detroit and be pro-

---

2 Medical News Sept. 12 1003

tected from free access to air, either by being placed under water or by being folded carefully in paper, they, like every other rubber article, deteriorate and lose both their elasticity and their strength It does not appear that the life of an elastic ligature exceeds six weeks or two months, and under unfavorable conditions, this period may even be reduced Furthermore the twine is much easier to introduce than the elastic, this fact being evinced by the varieties of complicated needles which have been made to facilitate the passing of the elastic ligature Any large needle will carry the twine

Fig 4 —Gastroenterostomy in dog Twine triangular stitch Shows mucosa of gut and serosa of stomach

It may reasonably be felt by some that enough work has not yet been done in an experimental line to demonstrate positively the efficacy of the twine ligature This may be true, but I beg to state that there are at the scientific exhibit the stomachs of two dogs operated on during the afternoon of June 2 in the presence of Dr Powers and Professor Weir Three and one-half days later these dogs were killed, and the openings were found to be complete The twine had cut through as rapidly as if it had been elastic In one the stitch had sloughed out and was detached In the other it was barely adherent to the margin of the fistula In point of time, then, and in certainty of action, if anything may be judged by a small but consecutive series, the twine is at least the equal of the elastic

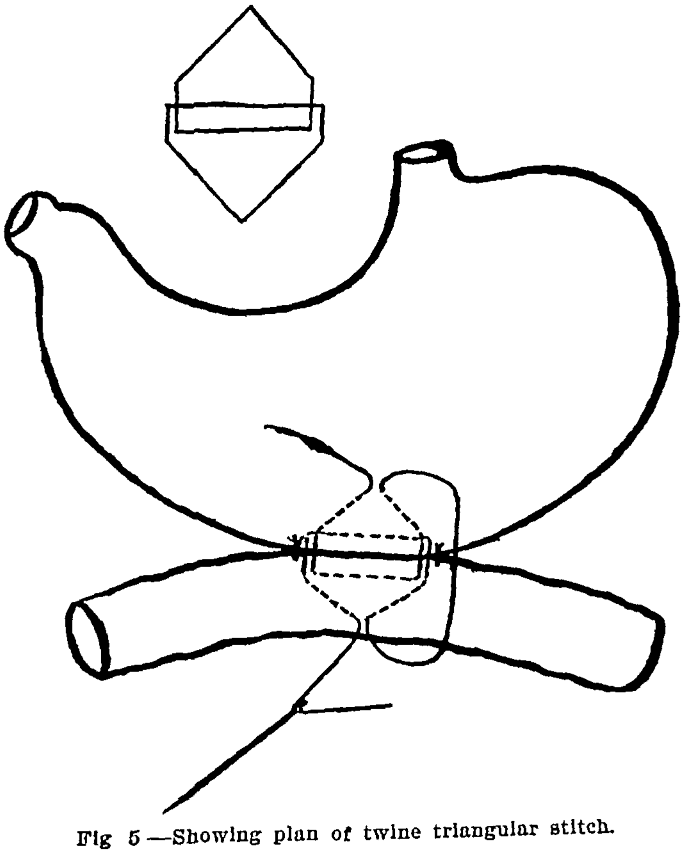

Fig 5 —Showing plan of twine triangular stitch.

The method of inserting the twine in triangular form will now be described in detail Figure 5 shows the outline of an intestine and a stomach This chart is one that Dr Weir has had made, and has kindly lent to me Two Lembert stitches are placed to mark two angles of the triangle The third stitch, or apex, is represented on the stomach above and on the gut below In the lower right-hand corner of the diagram, the stitch has been represented without the viscera It is to be noticed that it looks like two little houses, one right side up and the other upside down, placed on each other This fanciful relation is, of course, changed as soon as the apices are brought together The dotted lines in the diagram mark the area of twine which is within the lumen, and show how the Lembert stitches guide in inserting it There is no difficulty at all in putting this stitch in if one simply remembers to weave the twine from one viscus to the other, completing first one triangle in the gut and stomach, then *vice versa*

We have not followed Dr McGraw's technic in placing a posterior row of Lembert stitches to unite the stomach and the gut, because all our gastroenterostomies have been done on the anterior surface of the stomach, and the reinforcing stitches have been put in later Lembert stitches are certainly necessary in this technic It does not appear to matter whether they be interrupted or continuous, although we have usually employed the former It has been shown to be practical to make the triangle in the stomach somewhat larger than that in the gut

As previously intimated, no complicated needle is necessary to introduce the twine The one in use at the laboratory has been made from an ordinary steel bobbin, which was broken off at the required length and ground to a point

After the insertion of the twine, which always should be too strong to break with the hands (braided fish line serves the purpose well, although we have used the ordinary white commercial twine), a row of Lembert stitches is so placed as to encircle the region of the triangle The stitches first introduced serve again as guides for this procedure

The introduction of the twine can be accomplished in less than a minute and a half Like every other stitch it requires a little study and practice, but it is not a complex technic

It is a pleasure to state that without the untiring assistance of Mr Gordon, the student assistant at the laboratory, this work could not have been brought to its present stage, and I take this opportunity to thank him for many invaluable suggestions

264 West Fifty Seventh Street

THE DEFECTS OF THE MURPHY BUTTON, WITH SUGGESTIONS OF IMPROVEMENTS IN THE OPERATION OF GASTROENTEROSTOMY *

ROBERT F WEIR, MD, F.R.C S (HON)
NEW YORK

It is not proposed in this article at all to decry the merits of the well-known Murphy button, for it is conceded by everyone that by this admirable mechanical device, abdominal surgery has been largely advanced in the last decade Since its introduction by its distinguished inventor, however, an enormous experience as to its value as well as to its demerits has been acquired, of which it is well from time to time to take stock

---

* Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee Drs DeForest Willard, Charles A Powers and J E Moore

In the earlier anastomoses between intestine and intestine or intestine and stomach, or between the gall bladder and intestine or stomach, the usually employed incision demanded in its best digested form an opening which experience showed in a gastroenterostomy and in an enteroenterostomy should be at least two and one-half inches long to prevent its subsequent closure, and to complete the operation it was requisite that the edges of the applied gut and stomach, as in a gastroenterostomy, for instance, should first be sewn together and then the opening was to be rendered more secure by a second outer row of special sutures to bring and to keep together the apposing peritoneal surfaces This took considerable time, and the mechanical button much simplified the technic and materially diminished the duration of the operation, and particularly so, if one avoided as Murphy said should be done, using any sutures of safety to hold together the peritoneal surfaces peripheral to the button Many surgeons even now, however, do not trust entirely to the button itself for peritoneal union, but resort to the employment of these additional safety sutures, indeed, I may say from personal experience and from observation, that the majority of surgeons known to me resort more or less frequently to these safety sutures, and naturally with a corresponding sacrifice of rapidity of the operation These safety sutures are from time to time found to be of additional necessity by virtue of the tendency of the puckered-up intestine or stomach, when tied to the cylinder end of each half of the button, to protrude beyond the button edge when the halves of the button are crowded together This puckering-up and surplusage of tissue is much obviated, I have found, by using Carle's method, who, after the introduction of the button halves, sutures the extra long part of the intestinal or gastric incision with one or two Lembert sutures and leaves thus a smooth edge about the button shaft

All the earlier mechanical devices used in a gastroenterostomy, beginning with Senn's plates and Abbe's rings, and other contrivances continued along that same line, up to and including the Murphy button, had one merit of some little moment attached to them, and this was that until dissolved, if they were soluble, or dislodged, if they were not—they held the stomach and intestine in a more or less broad splint that protected the intestine from hanging so dependently from traction or from gravity action that kinkage at the suture point would likely ensue This kinkage, with the tendency of the spur on the other side of the intestine to act as a valve, as Keppler has shown, accounts for many cases of obstruction of the biliary and pancreatic secretion at the gastroenterostomy opening, which in turn produced the so-called vicious circle, with its upward regurgitation of these secretions into the stomach In this kinking, let me make it clear, that not only does the intestine take part in its production, but also the stomach, particularly if it is dilated, hence the various suggestions of suturing adjacent portions of the small intestine to the stomach is of little or no avail in obviating this difficulty Furthermore, the circularly punched-out opening in the anastomosed parts when a Murphy button of 27 mm in diameter has been usud in a gastroenterostomy, has, in my judgment, very materially aided in preventing the closure of the artificial opening thus made and in some seventy cases in which I have employed the button, in only one have I known this closure of a gastroenterostomy opening to have taken place Mayo and others have recorded a few instances, but compared with the multiple employment of the button this closure is but seldom encountered

There is another mishap of more frequent occurrence in using the button, and that is the occasional escape of the button into the stomach, where it may be recognized by an *x*-ray picture and yet be borne without distress by the patient, or it may beget symptoms demanding a gastrotomy for its relief To prevent this complication, I several years ago, as may be known to you, suggested the addition of ⅛-inch to ¼-inch flanges to be placed on two sides of the intestinal half of the button This has worked well, for in some thirty-three cases where it has been employed by me, in but one, and that quite recently, did the button slip into the stomach

All who have had some experience in gastric surgery must admit that comparatively often the button does not come out in spite of long waiting and patient and thorough investigation of the fecal discharges Carle estimated that about 78 per cent of the buttons were retained in the intestinal canal and were probably harmlessly lodged in the sulci of the large intestine Of late the *x*-ray has aided the surgeon in tracing the missing machine

Another disadvantage to which I will now refer is a somewhat unexpected one, and is due to the inevitable possibility of imperfection in the manufacture of the button It has been well emphasized by Murphy himself that the buttom should be well made I have seen the pawls, or the little projections that hold the telescoped buttons together, made of separate pieces and simply riveted or soldered to the main cylinder This is an error, and the best manufacturers make this part and the cylinder itself out of one piece of metal, but even this does not always protect the button from separating unduly Futhermore, the coiled spring contained in one of the halves of the button, and which is thought to be of service in keeping up the pressure as the tissues progress in their sloughing, may, rarely it is true, escape from its attachment and get loose, making an intestinal puncture possible I have had three instances in the last two years of such accidents, one when the catches became loosened, having been soldered, probably, in the other two the wire escaped its fastening In the latter case the buttons were made by manufacturers endorsed by Dr Murphy himself as proficient in their make

An additional defect is worth calling attention to, as it may explain some of these mishaps The corroding action of the gastrointestinal secretions on the metal of the button, is nearly always seen on all buttons, retained more than, say, three weeks The nickel-plating will be found to be gone, and if one uses—as at one time we did at the Roosevelt Hospital for economy's sake—the button several times after it has been cleaned, polished and renickeled by the maker, decided evidences of corrosion will be seen about the openings of the button This is fairly well exhibited in the accompanying Figure 1 the button in this instance having been used three times This corrosion may account in some cases for the slipping of the catches and the escape of the wires In my first case, when the button, made by a noted surgical instrument maker in New York, was used in a gastroenterostomy, some nine months later the patient underwent gastrotomy for persistent painful gastric symptoms and the button was found in the stomach separated into its two halves, no pawls or catches were to be found The second case was a gastroenterostomy with a button made by an endorsed manufacturer in Chicago, with my flange added to it The operation was done in a state neighboring to New York, and the patient wrote me later that on the twenty-ninth day the lower half of the large button came away On the thirtieth day a small spring was passed in a defecation On the sixty-seventh day the intact enteroenterostomy button passed, but up to 144 days, when last reported on by him, the other half of the large button had not appeared, and an x-ray examination failed to detect it He, however, did not have from this supposed retention any untoward symptoms He said his stools had been carefully watched

A third case has recently occurred where the button was passed the thirty-fifth day after a gastroenterostomy, in a complete form, but the wire spring had become loosened at one end, though still held by the grip of the button

A lesser accident, that only impairs the technic and does not affect the patient, is one that can be easily avoided Twice I found after suturing each half of the button in the intestine and in the stomach respectively that I could not force the male into the female cylinder, and that I had to rip out the imperfect half and put in a better one in one case, and in the second I had to take out both halves and put in other ones The imperfection in the buttons in these cases had been brought about by the pressure of a rather wide-holding forceps flattening out the round of the cylinders, so that they would not telescope Care in employing finely-pointed catch forceps has prevented any recurrence of the difficulty

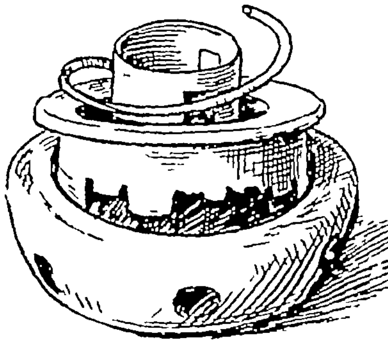

Fig 1 —Showing corrosion of button and loosening of the wire spring

With the objection that both surgeon and patient feel at leaving within the body a metallic device with the imperfections that are inseparable from any mechanical contrivance, it is not to be wondered at that many surgeons of distinction here and abroad have recently reverted to the previously cast-off simple method of incision and suture, or that others have tentatively tried to create new procedures of operation For my own part, I confess I am yet on the fence While the button has served me well in many cases, yet I feel uneasy in longer using it, and have in four cases lately tried to overcome still further its tendency to escape into the stomach by attaching in each of these instances the smaller entero-enterostomy button (which I always use to prevent the establishment of the vicious circle) to the flanged gastroenterostomy button by means of a stout but loose piece of silk, or preferably braided silk and linen fishing line, leaving the ends of the knot three or four inches long to hand down in the intestine By this procedure I hoped to secure, by the intestinal peristaltic action, a certain amount of tugging or traction by the lower button, which usually separates first, on the upper one I have resorted to this expedient in five instances, one of them was operated on four days ago[1], in one, death resulted in forty-eight hours from pneumonia, but in the other three everything went on happily, though I noticed that in one case, where the buttons were retained nearly forty days, that the silk had become quite friable Asbestos thread or fine rubber cord—not taut, however—might be employed Fishing line worked well in one instance See Figure 2.

The use of the oblong button has lately been applied to gastroenterostomy by Murphy and by Blake, but it does not appeal to me It gains a larger opening, with the greater risk of lodgment in the stomach and increased amount and variety of mechanical contrivance I look with more hope to the elastic ligature suggested by McGraw of Detroit I have not used this procedure, for, as given to us by him, the resulting opening is not longer than that made by the incision and not wide enough in my judgment to be sufficient guard against closure

I had determined to imitate the punching-out of the Murphy button by cutting out a round piece of the stomach and intestine and then completing the gastroenterostomy by the usual suture, when I made a suggestion to Dr Maury of the surgical research department of the College of Physicians and Surgeons of New York, to see if he could, on animals, contrive an elastic suture so as to bring about a decidedly large opening in all diameters This he has been able to effect, at first making a quadrilateral opening, and more lately a satisfactorily-sized triangular opening by a rapidly-introduced suture of twine applied by a technic even simpler than that presented by Dr McGraw[2] I believe we may anticipate a useful result to abdominal surgery from his investigations I shall certainly try the method in an early case

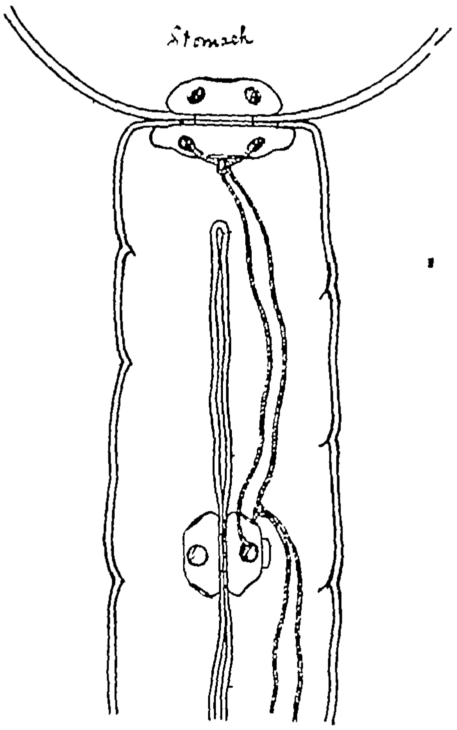

Fig 2 —Showing the flanged button and thread tractor attached to the enteroenterostomy button

---

[1] On the sixteenth day both buttons were discharged with the silk attachment unimpaired

Identity of Meat Poisoning and Paratyphus—The clinical course of poisoning from meat and of paratyphoid varies as the former is more acute, the latter subacute, but otherwise Trautmann announces that they are merely varying forms of an etiologically single infectious disease. His communication issues from the Hamburg Institute of Hygiene and is published in the *Zeitschrift f Hyg und Infkr*, xlvi, No 1

EXCISION OF THE ULCER-BEARING AREA IN GASTRIC ULCER*

WILLIAM L RODMAN, M D, LL.D
Professor Principles of Surgery and Clinical Surgery Medico Chirurgical College Professor Surgery and Clinical Surgery, Woman's Medical College of Pennsylvania.
PHILADELPHIA

Rash, indeed, would be the surgeon who advocated operation in all cases of gastric ulcer, but more rash would be he who practiced excision of the ulcer-bearing area in all cases operated on I wish it distinctly understood that it is only in certain well-selected cases that the proposed operation has, or may ever have, an accepted place in surgery We are all agreed that 25 or 30 per cent of the cases of ulcer of the stomach may be cured by medical means These will usually be the cases of acute round ulcer found in females under the age of 30 They are also frequently found in connection with chlorosis, and it has been found that, as a general rule, they heal under medicinal treatment It has also been learned that the chronic ulcers, usually found in males past the age of 40, are the ones which interfere seriously with the mechanism of the stomach and have to be treated very largely by mechanical, rather than chemical, means It has still further been found that gastroenterostomy, valuable as it is, and the operation preferred by a majority of operators, here and in other parts of the world, has its distinct limitations

Pyloroplasty, which was practically the first of these operations on the stomach, is infrequently practiced at the present time, unless we accept the operation of Finney, assuredly the best of its kind The objections to the Heineke-Mikulicz operation are, first, that it is dangerous to practice in open ulcers where the stomach walls are friable, second, the opening that is left (pylorus) is on a higher level than the rest of the organ, and the stomach muscle in its weakened condition is not able to lift up the gastric contents and propel them through the enlarged outlet The Finney operation undoubtedly possesses an important advantage over the Heineke-Mikulicz procedure, as it permits drainage in the natural position and will probably always overcome even narrow strictures The objection to it, however, is that it is not the best operation in open ulcers, inasmuch as the contents of the stomach must still pass over the ulcer or ulcers in order to reach the duodenum Gastroenterostomy though favored by a majority of operators, has been shown not to relieve all cases of hemorrhages, as Kocher and others have reported deaths after gastroenterostomy which apparently for a time had been entirely successful Neither does it prevent perforation as there have been many such cases reported after gastroenterostomy It does not nor do any of the methods in well-established use prevent cicatrices forming after the ulcers These result in stenoses, and possibly cause further trouble in the stomach

The operation of excising the ulcer-bearing area is especially indicated in cases of multiple ulcer It will be found not only that the acute, round or perforating ulcer is multiple in many cases but experience gathered in the last few years indicates that chronic ulcer is more often than otherwise multiple This has been insisted on by Mayo and others Moynihan states that it has been rare to find a chronic ulcer that was solitary If an ulcer is found at the anterior portion of the pylorus one is very apt to be found directly opposite on the posterior surface Owing to the fact that ulcers are so frequently multiple, the operation of simple excision of the ulcer, which I was disposed to think favorably of four years ago, and advocated, is sometimes inadequate and must be supplemented by a gastroenterostomy, otherwise it will fail Excision of one ulcer does little good if others are left behind Another reason for excision of the ulcer bearing area is the fact that malignant transformation frequently occurs in cicatrices left after gastroenterostomy, or any other operation which does not remove the lesions, but allows them to remain as a perpetual menace to their host

Some years ago Hauser estimated that 6 per cent of all ulcers of the stomach resulted in carcinomata at some future time, while Doyen thought that a very much larger percentage underwent malignant change I think we now have sufficiently accurate information to warrant us in saying that a large per cent of all gastric ulcers undergo carcinomatous change

Perhaps the very best information that we have on this subject is furnished from Rochester, Minn, where out of 157 cases of cancer of the stomach operated on by the Mayo brothers it was found that in 60 per cent of them there was a well-marked history of previous ulcer, although sometimes years elapsed between the benign and malignant condition When one remembers the fact that the topography or geography of ulcer and cancer is practically the same—that is to say, 80 per cent of all ulcers are located in or near the pylorus, and about the same per cent of carcinomata are found in the same region—one is led to the conclusion that ulcers more often degenerate into carcinomata than has hitherto been thought probable Another reason why excision of the ulcer-bearing area may be done to advantage at times is the fact that gastric and duodenal ulcerations so often coexist For this information we also owe more to Mayo than any one else He has found that in 12 per cent of his operative cases the ulcers were in the duodenum, and in 88 per cent in the stomach Moynihan states that he has practically never found a case of duodenal ulceration that was not accompanied by one in the pyloric portion of the stomach All agree that when duodenal ulcer exists, gastric ulcer is almost sure to be present

When we remember that duodenal ulcerations are far more likely to perforate than gastric, then I think it will be admitted that this is a strong plea for removing not only the pylorus, but the upper part of the duodenum, in such operations This can be very easily done, inasmuch as Mayo has shown that duodenal ulcers are in all instances limited to the first two and a half inches of the duodenum Further, all will admit that a pylorectomy, rightly done, leaves the stomach in a better condition for future usefulness than a simple gastroenterostomy, because, however well the gastroenterostomy may be done, whether it be by the excellent methods which have been demonstrated here to-day, or by any other method whatsoever, so long as the pyloric end of the stomach is patent a certain amount of the gastric contents will pass through the pylorus, cause irritation and lead to future trouble On this account Mayo has been compelled to reoperate 6 per cent of his 271 gastroenterostomies and of those reoperated and subjected to excision of the ulcer-bearing area all were completely relieved—a cogent reason why this operation should be done

TECHNIC

As 80 per cent of gastric ulcers are found very near the pylorus and nearly all that produce symptoms are so situated, it would seem that practically all the ulcer-bearing area could be removed by doing a simple pylorectomy One would not be apt to make a mistake in diagnosis and do this operation when not indicated, simply for the reason that ulcers in other regions are usually latent and do not give symptoms Moreover, when the stomach is exposed one will nearly always be able to decide where the ulcers are by observing the milk-like opacity of the peritoneum, by a puckering of the coats of the stomach, by dense adhesions, or all combined We should remember that ulcers situated about the lesser curvature are far more apt to perforate than those about the greater curvature (122 to 16) Instead of removing only the immediate pylorus, it is better, therefore, to make the incision obliquely, so as to remove at least one-half or more of the lesser curvature

---

* Read at the Fifty-fifth Annual Session of the American Medical Association in the Section on Surgery and Anatomy and approved for publication by the Executive Committee Drs DeForest Willard Charles A. Powers and J L. Moore

The pyloric end of the stomach can be removed in either of the two accepted ways, according to the case and fancy of the operator The second method of Billroth is, I think, to be usually preferred After the stomach and duodenal ends have each been permanently closed by double rows of sutures, a posterior gastroenterostomy is made The control of hemorrhage and suturing are made easy by the use of suitable clamps They also absolutely prevent escape of either gastric or duodenal contents The straight clamps used by Moynihan in doing gastroenterostomy, or the curved ones of Kocher, are admirably adapted to the purpose They should be covered with rubber tubing to prevent too great injury to stomach and bowel Both the pylorectomy and gastroenterostomy should be completed in an hour

The probable mortality of this operation should not exceed 10 per cent William Mayo has performed it seven times without mortality Were the mortality twice or thrice as great, it would still seem a perfectly justifiable procedure, as the mortality of ulcer under strictly medical treatment is at least 25 per cent, as admitted by nearly all medical authors, while Debove and Rémond place it at 50 per cent (including secondary deaths from anemia, consumption, etc) The operator will not choose this method in advance if the case seems to be a simple one, which will presumably yield to gastroenterostomy, but if, after entering the abdomen and carefully examining the stomach, he encounters conditions making the latter operation appear doubtful in its results, if not actually futile, then the more radical and ideal procedure should be carried out The conditions warranting the major operations are, to recapitulate 1, Multiple ulcers, 2, both gastric and duodenal ulcers, 3, threatened perforation of either, 4, repeated and dangerous hemorrhages, 5, a distinct tumor in patients past middle life, where the diagnosis between benignity and malignity is at best problematical

Every one with experience knows how difficult, almost impossible, it is, in many instances, to make a differential diagnosis between ulcer and carcinoma In such cases we should assume malignancy, actually existing or threatened, and perform a pylorectomy It is here well to recall the brilliant results of Mayo (thirteen operations, with one death), Kocher, Robson, Murphy and Moynihan, in their resections of the pyloric end of the stomach for cancer If it can be done, as Murphy states it was in 189 cases, by seven operators, with a mortality of 15 per cent, then, surely, a less grave operation, because less tissue is sacrificed, in better subjects, should give more favorable results If there be the same relative difference between pylorectomy in malignant and non-malignant cases, and surely there will be, as there is in gastroenterostomy, then the mortality following pylorectomy in non-cancerous patients should not be more than one-third what it is for cancer, or 5 per cent The Mayos had even a greater difference, or nearly four to one, as following gastroenterostomy in malignant cases their mortality was 23 per cent, whereas in their benign series it was but 6

Billroth's and other statistics of pylorectomy for cancer compiled prior to ten years ago are of little value and can not be accepted now, any more than statistics of operations for cancer in other regions Billroth, for instance, admitted a death rate of 23 per cent following his operations for cancer of the breast To-day we feel that from 2 to 3 per cent is more than an average, and 5 per cent should represent the outside mortality for the most radical breast operations The difference in stomach operations is noticeable from year to year, let alone from decade to decade, and the prohibitive mortality of twenty years ago for all operations on this organ has been succeeded by a definite but small mortality, and in almost every case is less than the medical treatment of former times

That excision of the ulcer-bearing area can be done with less mortality than follows the strictly medical treatment of this protean affection (gastric ulcer), with its hemorrhages and anemia of to-day, perforation and subphrenic abscesses of to-morrow, to say nothing of probable stenosis and more than possible malignant disease in after years, is not, I think, much longer to be seriously questioned

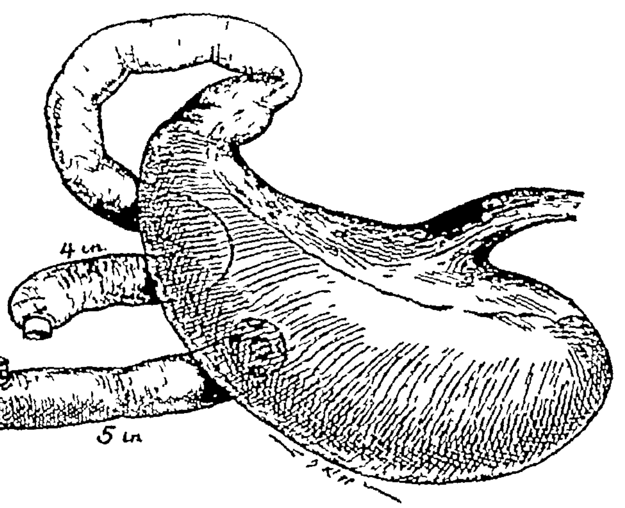
DISCUSSION

ON PAPERS BY DRS MAURY, WEIR AND RODMAN

Dr A J Ochsner, Chicago—My discussion will be limited to the McGraw ligature, but will not refer to the end results of gastroenterostomy or enteroenterostomy by means of the McGraw ligature, because my earliest case is not yet one and a half years old. When these cases have been done for a number of years, I think it will be wise to consider them and to speak about the ultimate value of the McGraw ligature It may be that after a number of years we shall find that our present experience as regards the immediate results will have been of no value whatever My experience covers 86 cases in which I have made use of the McGraw ligature, 68 of these cases were operated on at the Augustana Hospital, where I had the opportunity of following them closely, while the others were operated on in various places, and I have not been able to follow them carefully The only ones that will be utilized in these remarks are the 68 operated on at the hospital Of these, 19 were for carcinoma of the stomach Simple gastroenterostomy was done for the relief of obstruction of the pylorus caused by the presence of carcinoma, and of these three died. I should say, however, that the three would have died had I not used the McGraw ligature, but simply explored them and closed the abdominal cavity again I would not have operated by any other method The reason that I did use the McGraw ligature was because in my early experience I had used it in a number of cases which formerly I had closed without making an anastomosis Notwithstanding this fact, they lived for a considerable length of time, and some are still alive Gastroenterostomy furnished drainage which enabled the patients to build up again, and in some of them it stopped the rapid progress of the carcinoma There were 12 cases of benign stricture of the pylorus due to a healed ulcer, and all recovered. For acute ulcer of the stomach which had not entirely healed, which by its presence had either given rise to obstruction of the pylorus or to severe hemorrhage, and therefore indicated a gastroenterostomy, there were 33 cases, and 32 recovered. One died at the end of the third week, probably from a thrombus of the pulmonary, but no autopsy was permitted The patient died suddenly, apparently after having fully recovered One enteroenterostomy was made for a carcinomatous obstruction of the splenic flexure of the colon, which recovered Two enteroenterostomies were performed on one patient, who died This patient was very much depressed and never recovered from her depression She was so emaciated that, had it not been for the use of the ligature, I would not have done the operation at all I did a cholecystocolostomy for a carcinoma involving the common duct, a hopeless case, in which the gall bladder should simply have been opened, but instead of this I made an anastomosis by means of the McGraw ligature The operation was unsatisfactory, there was a thick walled colon and a thin walled gall bladder In the intestinal cases there were 67, with 5 deaths, and of these 3 were due to carcinoma and 1 to accident, a thrombus, and one to the very greatly depressed condition of the patient My mortality in gastroenterostomy has been smaller with the use of the McGraw ligature than with any other method The peculiar point about the gastroenterostomy with the McGraw ligature is in the fact that the patients show practically no shock It might be supposed that the reason for the absence of shock was in the fact that it is possible to do this operation with great rapidity In all abdominal work you have shock where you do a lot of manipulating While an assistant, I observed that certain surgeons constantly had frightful shock on the day following operation, and, on observing the conditions under which these various patients with similar conditions had been operated on, I found that those in whom the shock was very severe were the ones in whom there had been a great amount of manipulation My method is so simple that it is practically impossible to manipulate the abdominal organs unnecessarily, and this is the reason why the Murphy button has given such good results in comparison with the needle and thread If you have to sew for half an hour you are likely to do a lot of mischief outside of the operation itself

Dr. William J Mayo, Rochester, Minn —I am glad to note that Dr Weir believes with me that the button has done a great work He hesitates to give it up and comes out with a new device in which he uses a small button to lead the big button down, a sort of bait Supposing one button drops on the inside of the stomach and the little button is in the intestine, what would the connecting string do? In one of the first gastroenterostomies ever done the patient died from inanition because the opening was made low down in the ileum, throwing the greater part of the small intestine out of use Any one who goes into this question carefully must be convinced that the anterior operation, by being compelled to go down on the small intestine on an average about twenty inches, is not so good an operation as the posterior method, with a high jejunal opening It may be said that the difference of a few inches will not matter, but I believe that it is important We know that secondary jejunal ulcers, because of the acid gastric secretions being turned into the intestine through the gastroenterostomy opening, have occurred almost entirely with the anterior operation In the posterior operation the mucous membrane is better able to protect itself, and when it has occurred with the posterior operation it has been when a long loop has been formed As to the Murphy button, I must say that nearly all I know about gastrointestinal surgery has been taught me by this button, and I have given it up with regret I still use it in certain cases of gastrectomy where sufficient suturing has already been done. As to Dr Ochsner's method of doing gastrectomy and using a McGraw ligature to make the gostroenterostomy, I should have to think about it a few times before I could quite satisfy myself as to the safety of completely cutting off the little pouch of the stomach that was left and the intestine, even for the time needed for the ligature to cut through It is, however, a quick method, and that is what we need in cases of gastrectomy for cancer, but the Murphy button is just as speedy and gives an immediate opening I would say that the McGraw ligature has no particular place in surgery of the stomach, except in a few cases of carcinoma, in which the anterior operation is preferred because one does not like to turn a stomach with a considerable tumor out of the abdomen, and in gastric cancer there is a great reduction of gastric juice, and therefore, less danger of secondary jejunal ulcer Ochsner's results, however, have been unexcelled One can do gastroenterostomy very quickly with the simple suture after the posterior method There is no reason why mere suturing should take more than from twelve to seventeen minutes, and our results have been more than satisfactory, and we prefer and practice it excepting in the exceptional case in which the saving of five minutes gained by the button or McGraw elastic ligature may be of great importance As to Dr Rodman's operation, I believe it is an ideal one, but we can not carry it out in all cases We must say to ourselves that it is a good deal of an operation for a simple ulcer Of course, there is danger of malignant degeneration, and if the pylorus is not completely closed there is a possibility of secondary trouble It may be said that if the gastroenterostomy is placed at the bottom of the stomach, primary vicious circle does not occur In some cases secondary difficulty has arisen, which has sometimes been due to food working through the pylorus In looking for the particular group in which these secondary troubles took place, I found it was in those cases where the pylorus was more or less open Food will pass from the pylorus into the proximal loop and then will have to pass with the bile over the top of the anastomosis, causing dragging and contraction If simple gastroenterostomy is done in a case with an open pylorus enteroanastomosis should be done to prevent the latter sequela We would think that a low point gastroenterostomy would drain the stomach anyway, but intra abdominal tension prevents gravity action, and muscular contraction carries the food out of the pylorus I believe Dr Rodman's operation is an ideal one and is indicated in a certain class of cases I have done it seven times and the patients have recovered and stayed well

Dr. John B Murphy, Chicago—Dr Weir coddled the button a little more than I would It has more mechanical difficulties in its construction than he has stated and it is more frequently improperly made It is a little difficult to get members of the medical profession, not to speak of manufacturers of surgical instruments, to appreciate the points in a perfect instrument I have found that all kinds of metals have been used in the manufacture of the button, and have even known of the springs have been made of steel You all know how long a steel spring would withstand the gastric secretions—just a few hours—before dissolved by the acid This does not change the fact that the button is easily constructed, the brass, German silver and aluminum will answer all purposes and a manufacturer is a criminal who makes them of other materials He was very modest in his statment as to the number of times the button falls into the stomach, but how rarely it has caused trouble I have used Dr Weir's modification and have also had the experience of its dropping into the stomach It subsequently was passed The effect of every method of intestinal anastomosis must depend on certain elements 1 Exact apposition at time of operation 2 Continued apposition until organic union takes place. 3 All accomplished with the least manipulation 4 Operation in the shortest possible time, as time means exposure and manipulation. 5 Union in healthy tissues These are all easiest of attainment up to date by using the button It was brought out by Dr Ochsner that the performance of certain acts while the patient is on the table often causes death The most important of these is excessive manipulation, and the operator who uses his hands and sponges too freely in laparotomies is a most dangerous one I recently did a gastroenterostomy by suture, but it was not the easiest nor the safest method One does not need to have a button to do an anastomosis, as it can be done quickly with suture in trained hands The position of the anastomosis as brought out so forcibly by Dr Mayo is very important, i e, sufficient of the bowel on the proximate side of the obstruction must be removed I believe many cases of vicious circle in gastroenterostomy have been due to the use of too long a loop (12 to 18 in of jejunum) for either anterior or posterior fixation In the posterior position the important point is the change of position of the stomach after relief of the obstruction i e, the stomach again resumes the vertical position so the union should be three or four inches from the pylorus and the button should be inserted in the jejunum from three to five inches from the ligamentum Treitze, never from twelve to eighteen inches below the origin of the jejunum As to Dr Rodman's method, it is admirable In all cases of simple ulceration of the stomach without adhesion to the liver or gall bladder it seems to me it is the ideal operation, because it once and for all re establishes practicably the union of the stomach with the intestine in almost its normal relation and avoids a secondary opening, but the question of mortality must be settled by the clinical test As to the cause of contraction of the opening, it is due to excessive cicatricial deposit rather than to a re establishment of pyloric patency This is always true so far as intestinal contractions are concerned As to the contraction in gastroenterostomy, it was supposed to be due to the cessation of the necessity for an additional opening I recently had a case discrediting this theory Two years after a button gastroenterostomy the opening admitted two fingers freely and the pylorus was patent It seems to me there is still to be accomplished one modification, and that is the modification of closure of the pylorus or the first portion of the duodenum permanently in every case of gastroenterostomy without increasing the severity of the operation This has not been done by a method which does not involve additional hazard All methods so far increase the risk, and the ideal operation has not yet arrived, but I am looking for some one to bring it out The Monprofit method of jejunal posterior gastroenterostomy with the button seems the most simple and effective It consists of division of the jejunum four or five inches from its origin and inserting half of the button in the proximal end The other half is put through the open end of the distal portion and carried down for five inches, where a small incision in the lateral wall of the jejunum allows the cylinder to protrude It is then coupled to the other half of the button in the proximal end of the jejunum, and the distal end is buttoned to the posterior wall of the stomach This avoids vicious circle and is quickly performed



Dr Robert H M Dawbarn, New York City—Dr Weir's first objection to the Murphy button was his allusion to the special forceps which Dr Murphy uses to hold it and Dr Weir states that it results in flattening of the button For the past ten years I have used two corks instead of forceps, and the method is so simple I hesitate to mention it The corks act as handles If the first half is not drawn so tightly as you think so that the button drops back into the intestine, the cork prevents it going any farther

Dr L L McArthur Chicago—I have been doing some work along the same line as Dr Maury It had seemed feasible to make an anastomosis by the use of the crushing forceps much as Doyen did his closure of the intestine where resection and side to side anastomosis was to be made I therefore crushed given areas and made a simple circular suture opposing these two crushed surfaces I then thought to cut off the nutrition of the crushed area by an additional insertion of the suture, which should, by tightly drawing and constricting the crushed surface, shut off all possibility of circulation In both of these efforts to get the anastomosis I failed I have shown my failures to prevent others from wasting any more time in this way Under certain circumstances traumatic in character, tissues are met with in which the mere apposition by suture of the neighboring intestine will be sufficient to repair the damage done My specimens show that although no lumen can be made by opposing such crushed surfaces, the suture material employed to cut off nutrition penetrates and finally escapes into the intestine

Dr A Palmer Dudley, New York City—I recently operated on a case of cancer of the uterus, in which I attempted to do a hysterectomy, and the small intestine was so friable that while breaking up the adhesions it went into two parts I inserted the button and waited nineteen days for it About this time the nurse became careless and I was getting doubtful, when the patient developed a fecal fistula Still missing the button, I probed a fistula and got a marked click On further investigation I found the button and took it out through the same opening in which I had put it I published a paper on this subject in the *Journal of Obsterics*, but apparently it has only been seen by a very few I think I hold the record for putting in and taking out a Murphy button through the same incision

Dr Floyd W McRae, Atlanta, Ga—At the time Dr McGraw read his original paper before this Section, some years ago, Dr J McFadden Gaston was presiding, and Dr McGraw gave Dr Gaston the credit for being the originator of this ligature We are, therefore, doing Dr Gaston an injustice by calling this ligature the McGraw As to the gastroenterostomy, I wish to say that the most beautiful work I have seen is the operation which Dr Mayo does with his modification as applied to this operation I have seen him do it in thirty five minutes

Dr Samuel Lloyd, New York City—I performed a number of operations some years ago with the McGraw ligature and found that it acted very well and cut through rapidly, which is its chief advantage I think rubber better than twine because it is more readily sterilized Cutting off the pylorus is a subject which is worthy of more attention I have done it several times without any difficulty In a certain number of cases food may be given in twenty four hours, and I think that in Dr McGraw's original paper the time was referred to Rubber has the advantage over twine in that it begins its action quicker and we can begin feeding more promptly One great advantage in the McGraw operation is the use of the McClain needle It makes a shell for the rubber and tearing and pulling are entirely obviated You can determine the size of the opening with the McGraw ligature I remember doing the McGraw operation in a benign case, one of kinking of the duodenum A gastroenterostomy was done and the abdomen was found full of adhesion Two years after operation I was obliged to open the abdomen again for intestinal obstruction which seemed to be high up I suspected that the McGraw operation had been a failure and that I should have to make a new opening in the stomach, but on examination found that the original anastomosis admitted two fingers of my hand very readily

Dr Maury—Last fall we endeavored at the laboratory to follow up some suggestions made by Dr Mayo relative to the closure of the fistula in the event and as a result of the pylorus being open We closed the pylorus in the case of six dogs and inserted the usual McGraw elastic ligature Within thirty six hours all these dogs died Their symptoms resembled those of tetany The case reported by Dr Ochsner has an important bearing on the relation of tetany to the gastric mucosa As to Dr Lloyd's remarks, I am not aware of his having had any information whatsoever as to the rate at which twine if used instead of elastic, will cut through If as has been shown to be the fact at the Columbia laboratory it cuts a complete opening before three and a half days, it must evidently begin to cut some time prior to that As to sterilization, I believe it to be as easily accomplished with twine as with elastic by simple boiling Twine is easier to obtain and has the distinct advantage of not deteriorating with age

Dr. Weir—The difficulties I have experienced occurred in buttons made by instrument makers who were indorsed by Dr Murphy, hence the more likely to happen with less expert manufacturers Dr Rodman s suggestion is a scientific one and worthy of consideration There is one point that Dr Mayo brought out by inference and that is that the procedure is one only to be used where the gastroenterostomy or other procedure has failed This should be strongly emphasized

Dr Rodman—One can complete a pylorectomy in any way that he pleases, either by the first or the second method of Billroth Personally I should think it better to close it entirely The principal claim for this operation is the fact that there is a large and unknown per cent of cases of gastric ulcer which result in malignant change and that this is an increasing per cent all will admit It should only be resorted to in cases where it would seem that probably a gastroenterostomy would not prove successful as for instance where there were multiple ulcers In those cases where the ulcer is large and where the tumor is accompanied by glandular involvement, as in a certain per cent of benign ulcers so that no one could possibly say that he was dealing with a benign condition, then I say it is certainly a rational procedure for in such a condition we have to recognize and admit that there is a fair probability at least of malignant disease in men over 50 Every one realizes the fact that chronic ulcer of the stomach so often forms adhesions and takes in the lymphatic glands that it is not possible at the time of the operation to say that it is benign Kehr and others have removed tumors that they supposed to be malignant which proved to be benign I can not believe that the mortality can possibly be 30 or 40 per cent It should not be followed by a mortality of more than 15 per cent. Even in malignant disease we realize that pylorectomy has reduced the mortality to less than 30 per cent It must always be an operation followed by a somewhat heavier mortality than gastroenterostomy Mayo did not believe it would be followed by a mortality as great as that Gastroenterostomy has a mortality of 5 or 6 per cent There is a difference, but it is not very great and in favorable cases it seems to me that it may have an accepted place in surgery

BORIC-ACID POISONING

REPORT OF A FATAL CASE, WITH AUTOPSY

CHARLES L BEST M S
CHICAGO

From the Pathological Laboratory of the University of Chicago

The opinion appears to exist that boric acid, even in large amounts, is entirely innocuous to the human body when applied externally to wounds, suppurating cavities, etc That this is erroneous and that the surgeon must be on his guard against its too free usage as it is not impossible for a fatal issue to ensue, is shown by the literature, in which five cases of severe intoxication and four deaths are reported in addition to the case at hand These cases all resulted from the prolonged irrigation with saturated solutions of boric acid or the packing of large cavities with the dry powder

Welch[1] reports his experience in the treatment of leucorrhea, in which he packed the upper third of the vagina with boric acid allowing it to remain until liquefied, usually two to three days This was repeated every seventh day In three cases intoxication resulted, and are reported by him as follows

Case 1—Two hours after the first treatment the patient was found with the skin cool, pulse feeble, respiration weak, eyes sunken and dull and the mind unclouded but despondent

Case 2—Two days after the seventh treatment there was a marked depression of the nervous system and a pronounced acid discharge from the vagina The skin of the hands, face and feet was swollen, became charred and finally exfoliated All motion was very painful

Case 3—Two days after the seventh treatment the patient was found in a state of collapse, low spirited, the pulse feeble, the eyes sunken, the face dusky, and general weakness There was great pain in the vagina, the mucosa of which was corroded, and much discharge from the part Temperature, 97 6, pulse, 60 The symptoms did not subside for a week, in the meantime the patient being at times cold, hysterical and prone to melancholy The skin exfoliated in branny scales All three cases recovered

Spencer,[2] after an operation for syphilitic necrosis of the ankle joint packed the cavity with one-half ounce of boric acid This was repeated on the seventh day, and on the fourteenth nausea and vomiting set in, not yielding to treatment Other symptoms were restlessness, insomnia, hiccough, weakness, emaciation, rapid pulse, some coryza, inflammation of fauces and pharynx, bronchitis, an acid discharge from the anterior nares and a well-marked papular erythema over the face, neck, arms and chest The symptoms came on gradually, increasing for three days, when the dressings were changed, and in ten days they had disappeared

In addition, he speaks of two cases, one in washing out a lumbar abscess, and the other the pleural cavity, with a 5 per cent solution of boric acid, followed by death in both cases, the symptoms being nausea, vomiting, hiccough, slight temperature, bronchial catarrh, a weak, rapid pulse and well-marked papular erythema The report of these I was unable to find

Hun,[3] after irrigating the pleural cavity with 16 ounces of a saturated solution of boric acid, found his patient in the evening covered with a papular erythema, and with a rapid, soft pulse A second irrigation on the following day aggravated these symptoms, and nausea and vomiting set in The treatment was discontinued and the patient recovered

Molodenow[4] used a 5 per cent solution very freely for washing out the pleural cavity in one patient and a lumbar abscess in another This treatment was continued for one hour Uncontrollable vomiting set in in both cases, followed by an erythema of the face and neck, and death from cardiac paralysis Autopsy was not secured

Williams[5] irrigated freely a case of empyema, the treatment extending over a period of two months, and finally placed 5 ounces of the dry powder in the cavity Delirium set in, shortly followed by uncontrollable vomiting, an erythema over the body, cardiac paralysis and death Autopsy was not secured

Rose[6] fully reports a case, which may be summarized as follows

History—Boric acid was freely used in the treatment of a large open sore on the right thigh On the fifth day a profuse diarrhea set in, but there was no change in the general condition The mind was clear, temperature normal, with pulsation slightly increased Later vomiting set in and the granulations assumed a sluggish appearance The boric acid was discontinued The diarrhea and vomiting, which consisted chiefly of mucus and water became uncontrollable On the ninth day the intellect was still clear, but the eyes staring, the body was bathed with a cold, clammy perspiration, and there was great weakness The hiccoughing and the vomiting were but partially relieved by morphia The urine for the last few days was intensely acid The temperature was 97 4, pulse, 105 Death occurred on the following day, the temperature being 96, the pulse 140 Just before death the tongue was red and moist, the vomiting almost continuous, and the urine almost completely suppressed carefully controlled (The difficulty of fulfilling the second condition can be readily seen The others were met satisfactorily)

The experiments carried out thus far show that the solution, while not so perfect a protection to the patient as intact gloves, is infinitely superior to the bare hands, and is equal to or superior to the glove, considering the chances of puncture

The rubber coating is slightly permeated by the perspiration, but perspiration is limited by the coating just as it is by the rubber adhesive plaster

However, Harrington of Boston has shown that the secretion from the sweat glands is not septic, while epithelium and the secretion from the hair follicles are The hair is glazed over and matted to the skin by the rubber solution, and its epithelium does not escape after applying the solution as does the perspiration

The experiments were carried out by my assistant, Dr Arthur D Dunn (The figures show the colonies obtained in the agar plates from the washings)

* Countless

In this series the rubber solution was poured on and allowed to dry on the hands without friction The method of using friction while applying the solution at operations is open to the criticism that microbes on or near the surface are worked up through the solution

METHOD OF PREPARATION

The method of preparing the rubber solution, as kindly furnished by E von Hermann, chemist, Chicago, is as follows

1 Care must be taken to cut the gutta percha chips in small pieces

2 Wash in formalin, full strength, and dry

3 Macerate the chips in benzine or acetone for three days, then filter through cotton which has been in formalin vapor for 48 hours Repeat the filtering twice and then the solutions are ready for use The benzine is sterilized by boiling it in a water bath in a strong, securely corked bottle Repeated culture tests of the solution prepared in this manner all proved sterile, 1 per cent carbolic acid may be added without producing irritation of the skin, but is unnecessary Formalin will not mix with the solution and therefore can not be used The solution will not stand boiling as it destroys the adhesiveness The chloroform and carbon solutions are not advisable as they are too severe on the operator's hands, and are expensive

At my suggestion the chemist macerated gutta-percha chips in benzine, acetone, chloroform and carbon tetrachlorid, and found the first two the best and cheapest the best, as they form a thoroughly tough cover for the hands and have the most lasting qualities They are not detrimental to the hands even after several weeks' usage Not only that, but the skin is as soft and smooth after a full day's operating as it was on beginning They are the cheapest, as the solution can be made (work not included) for 25 and 50 cents, respectively, per pound A 4 per cent solution is best, a higher percentage of gutta-percha may be used, but it rolls and scales off in an unpleasant way

He also experimented with pure celluloid and acetone, and Schering's celloidin with ether and alcohol These form a good covering, but are too expensive (about $1 35 per pound) for general use

For practical purposes, it seems to me the best way to put this on the market is to place the sterilized chips in small envelopes the same as dry catgut, having a sufficient quantity in each to make a 4, 8, 12 or 16 ounce solution The operator can then have sterilized benzine in his operating room and add the gutta-percha, thus making fresh solutions These, like soft rubber goods deteriorate with time, and if kept long in a hot room This is all avoided by keeping a supply of rubber chips as above mentioned

METHOD OF USE

The best method of applying is by dipping the hands into a small basin containing the solution It should be worked in around the nails and tips of the fingers and should be applied as high as the elbows Between operations the hands may be washed with soap and water, spirits of soap, alcohol, bichlorid, carbolic acid or formalin solution, without interfering with the rubber coating Brushes, however, should not be used After cleansing the hands and before proceeding with another operation, the fingers are redipped, as the coating wears off, but one application on the hands and forearms is sufficient for the entire day The skin of the operator does not become "water logged" or shriveled with the solution, as it does with the rubber glove The coating is best removed by washing the hands in benzine and drying rapidly with a towel

I quote as follows from a letter from Dr Van Buren Knott of Sioux City as an example of many received

> I have used the gutta percha solution for three weeks and am very much pleased with it I think it a very valuable protection during operative procedures I have used the solution with and without gloves, and in either manner have been well pleased I find it a most excellent means of protecting the hands in the application of plaster of paris, as it prevents the plaster from sticking to the skin and avoids the harsh rough feeling which follows the application of a plaster cast

Since my previous report, I have used the solution on my hands and on the operative field in all operations, septic and non-septic, and am convinced that it is a simple and practical means of protection for the operator and patient

---

Overcrowding of the Profession in Belgium.—The *Gaz Méd Belge* remarks that it might be a good plan to shut up the medical colleges for ten years instead of hatching out a new crop of physicians every year There is no room for even those already on hand it asserts

Special Articles.

THE UNITED STATES PUBLIC HEALTH AND MARINE-HOSPITAL SERVICE

PART II. THE SERVICE AS IT IS TO-DAY

(Concluded from page 733.)

SERVICE PUBLICATIONS

The surgeon general is required by law to transmit to Congress an annual report, containing a detailed account of the operations of the service for the previous fiscal year.

The quarantine law of 1893 makes it the duty of the service, under the direction of the Secretary of the Treasury, to collect sanitary information from all quarters of the globe, and to publish and transmit this information to collectors of customs, state and municipal health officers, and other sanitarians. The sanitary condition of the world's ports is thus reported and published weekly in the *Public Health Reports* of the service. Tables and special reports showing the prevalence of epidemics and contagious diseases in the United States and foreign countries are also published weekly in the *Public Health Reports*.

Supplements to the *Public Health Reports* and reprints from it are published by the service for distribution in communities afflicted by epidemic diseases. Publications of this character bearing on smallpox, scarlet fever, yellow fever, diphtheria, typhoid fever, measles and malarial fever are printed and distributed by thousands each year.

There is a great demand for the bulletins of the hygienic laboratory. These cover a wide scope in the field of experimental and preventive medicine, as indicated by the following list of bulletins published:

No. 1.—Preliminary Note on the Viability of the *Bacillus pestis*. M. J. Rosenau.

No. 2.—Formalin Disinfection of Baggage Without Apparatus. M. J. Rosenau.

No. 3.—Sulphur Dioxid as a Germicidal Agent. H. D. Geddings.

No. 4.—Viability of the *Bacillus pestis*. M. J. Rosenau.

No. 5.—An Investigation of a Pathogenic Microbe (*B. typhi murium* Danyz) Applied to the Destruction of Rats. M. J. Rosenau.

No. 6.—Disinfection Against Mosquitoes with Formaldehyd and Sulphur Dioxid. M. J. Rosenau.

No. 7.—Laboratory Technic: Ring Test for Indol. S. B. Grubbs and Edward Francis. Collodium Sacs. S. B. Grubbs and Edward Francis. Microphotography with Simple Apparatus. H. B. Parker.

No. 8.—Laboratory Course in Bacteriology and Pathology. M. J. Rosenau.

No. 9.—Presence of Tetanus in Commercial Gelatin. John F. Anderson.

No. 10.—Report on the Prevalence and Geographic Distribution of Hookworm Disease (Uncinariasis or Anchylostomiasis) in the United States. Ch. Wardell Stiles.

No. 11.—Experimental Investigation of *Trypanosoma lewisi*. Edward Francis.

No. 12.—The Bacteriologic Impurities of Vaccine Virus: an Experimental Study. M. J. Rosenau.

No. 13.—A Statistical Study of the Intestinal Parasites of 500 White Male Patients at the United States Government Hospital for the Insane. Philip E. Garrison, Brayton H. Ransom and Earle C. Stevenson. A Parasitic Roundworm (*Agamomermis culicis* n. g., n. sp.) in American Mosquitoes (*Culex sollicitans*). Ch. Wardell Stiles. The Type Species of the Cestode Genus *Hymenolepis*. Ch. Wardell Stiles.

No. 14.—Spotted Fever (Tick Fever) of the Rocky Mountains: a New Disease. John F. Anderson.

No. 15.—Inefficiency of Ferrous Sulphate as an Antiseptic and Germicide. Allan J. McLaughlin.

No. 16.—The Antiseptic and Germicidal Properties of Glycerin. M. J. Rosenau.

The Yellow Fever Institute was founded in the bureau in 1901 for the purpose of learning all that could be learned about yellow fever, including its etiology, and to bring to this work the aid of all reputable physicians who might desire to take part therein, its membership including, besides the officers of the Marine-Hospital Service, special investigators both in this and foreign countries. It is divided into four sections, the chairman of each section being one of the division officers of the bureau to which, under bureau organization, matter of a kindred nature would naturally come. These, together with the chairman and secretary of the institute, form an executive board to consider, especially with regard to publication, the contributions received from the members.

Thirteen bulletins have been published by the institute, and two working parties sent to Vera Cruz, Mexico, to study yellow fever. Although these investigators did not find the specific cause of yellow fever, they contributed a great deal of valuable information concerning the mode of transmission of the disease, and the life history and characteristics of the *Stegomyia fasciata*.

The bulletins of the Yellow Fever Institute are of particular interest to the people of the southern states, and of scientific interest to the profession at large. Thirteen of these bulletins have been published, and combined they present all that is known of the history, etiology, and characteristics of yellow fever.

THE HYGIENIC LABORATORY

The work of the service in scientific research is inseparably connected with the growth of the Hygienic Laboratory. The Hygienic Laboratory was established in August, 1887, at the United States Marine-Hospital on Staten Island, New York. In 1891 the bureau in Washington was given more commodious quarters in the Butler Building, and the laboratory was transferred from New York and occupied the top floor of that building for about twelve years. Much of the work done in the Hygienic Laboratory during these years had a direct bearing on the needs of the service. The disinfecting methods used by the service in quarantine and epidemic work were perfected and placed on a scientific basis largely through the work done in the laboratory. The result is shown in the elaborate system of disinfecting apparatus which, developed by the needs of the service, has been mechanically improved and scientifically tested until now it is conceded to be the most perfect of its kind in the world.

The service not only systematized and perfected the methods of utilizing steam and sulphur dioxid and other agents in the disinfection of ships and other habitations or objects, but was the first to exploit and test the value of that now universally employed agent, formaldehyd.

The advantage of training officers who have special aptitude for research work was early appreciated by the service, and such officers were detailed from time to time for duty in the Hygienic Laboratory. These courses were frequently supplemented by foreign details, with the opportunity of studying in some of the European scientific centers. The first authoritative publication on the treatment of diphtheria by antitoxin was issued by the service, and was the result of personal instruction given an officer of this service by Behring and Roux, who separately announced their discovery of the Budapest meeting of the International Medical Congress.

Another officer of the service in the laboratory of the Pasteur Institute studied plague and the methods of preparing a curative serum and prophylactic for its prevention. The work of preparing a prophylactic serum for plague was carried to consummation in the laboratory, and thousands of doses of Haffkine's prophylactic against plague have since been produced in the laboratory, and have been distributed to quarantine stations in the United States, Hawaii and the Philippines.

The first diphtheria antitoxin manufactured in the United States was made in the Hygienic Laboratory.

The rapid growth of the laboratory work and the necessity for a separate building were brought to the attention of Congress, and in March, 1901, a section of the act making appropriations for the sundry civil expenses of the government provided $35,000 for erection of the necessary buildings, and directed the cession, by the Secretary of the Navy, of five acres of the old Naval Observatory site for laboratory purposes The act approved July 1, 1902, changing the name from the Marine-Hospital Service to the Public Health and Marine-Hospital Service, greatly enlarged the scope of the laboratory work and provided for an advisory board, to be made up of an officer appointed from the Medical Corps of the Army, an officer from the Medical Corps of the Navy, a scientist from the Department of Agriculture, and five appointees from civil life not connected with the service of the government, who should be personally skilled in laboratory work in relation to the public health The advisory board consists of Prof Wm H Welch, Prof Simon Flexner, Professor Sedgwick, Prof Victor C Vaughan, Prof F F Wesbrook, Major W D McCaw, U S A, Surgeon J F Urie, U S N, and Dr Salmon, U S Department of Agriculture

The expansion of the laboratory, as effected by this act, provides for the addition of three new divisions, viz, chemistry, medical zoology and pharmacology

The building is now completed, and the work of the new divisions well under way The division of zoology has already done considerable work in the investigation of parasitic diseases of man, and the division of pharmacology has been engaged in the scientific investigation of drugs with regard to their potency and pharmacopeial purity

In accordance with an act passed July 1, 1902, providing for the licensing of all establishments engaged in interstate traffic, or in traffic in the District of Columbia, in viruses, serums, toxins, antitoxins and analogous products, the specimens and samples of these products are purchased in the open market and examined in the laboratory for purity and potency The result of this work has been that establishments that could not comply with the requirements of the law have gone out of business, and the larger firms engaged in the manufacture of such products have been required to maintain a high standard of excellence Where formerly it was common to find hundreds of micro-organisms in vaccine, the number found now rarely exceeds 100, and there is noted an almost entire absence of pathogenic and pyrogenic varieties

The hygienic laboratory is now preparing a standard diphtheria antitoxic unit for use in the United States in accordance with requests of manufacturers and recommendations passed by the American Medical Association and the American Pharmaceutical Association

The course of instruction now given in the laboratory to officers of the service covers a period of about twelve months Officers having completed this course are competent to do research work The service now has fifteen officers who have taken this course, and who are stationed in various parts of the world pursuing original investigations

In addition to the work indicated above, and to investigations of various contagious diseases, their etiology and modes of transmission, officers in the hygienic laboratory have done much work in the investigation of polluted water supplies, disinfection of railway coaches and other subjects affecting the public health

The results of the work done in the laboratory are published in the bulletins which are issued from time to time, a list of which has already been given under the head of service publications

Officers are frequently sent to investigate the cause or prevalence of disease A commission of service officers investigated and reported to the Senate on the prevalence of leprosy in the United States in 1902 The prevalence and geographic distribution of hookworm disease and its baneful effects in the south were demonstrated by an officer of the service and reported by him in the Hygienic Laboratory Bulletin No 10 Another officer of the service was sent last year to investigate a new disease, the so-called spotted or tick fever of the Bitter Root Valley in Montana The results of his studies are set forth in Hygienic Laboratory Bulletin No 14

IMMIGRATION INSPECTION

The medical inspection of immigrants became one of the duties of the service by act of Congress approved March 3, 1891 The subsequent immigration acts of 1893 and 1903 also provided that the medical inspection should be made by officers of the service

Under our immigration laws, persons suffering from loathsome or dangerous contagious disease, insane persons, idiots, epileptics, and persons likely to become a public charge, are excluded, and it is the duty of the medical inspector to detect such persons and certify their physical condition for the information of the immigration authorities The service also takes charge of the sick in the immigration hospitals, and has supervision over the hygienic surroundings of detained immigrants

Officers stationed abroad for duty in the United States consulates, under the quarantine law of 1893 have, in addition to their quarantine duties, examined aliens embarking for the United States They recommend to the steamship companies the refusal of passage to such aliens as would be likely to be rejected at United States ports under our laws This foreign inspection is now being made by officers of the service on duty in the United States consulates at Naples, Italy, Kolbe, Nagasaki, and Yokohama, Japan, Hongkong and other ports in the Orient The rejection of the alien at the port of embarkation is of such obvious advantage to the rejected alien, to the steamship company, and (in the case of a diseased alien being rejected) to the other passengers who would be exposed to infection on shipboard, that it is likely that provision will be made for maintaining a foreign inspection at all the principal European ports

The inspection of immigrants is carried on at all our seaports, and at points on the Canadian and Mexican borders where there is direct communication by rail or steamboat between the United States and either of the two countries mentioned

The magnitude of this inspection work can be appreciated if the fact is borne in mind that more than 850,000 immigrants arrived in the United States and were inspected by officers of the Public Health and Marine-Hospital Service during the fiscal year ending June 30 1903

Officers of the service receive special training for their work as medical inspectors of immigrants The immigration station at Ellis Island, New York, is used by the service as a school of instruction where young officers, before being detailed for immigration duty at one of the other ports of entry, are trained in the detection of the particular dis[illegible] and defects likely to be found in immigrants

FUTURE WORK [illegible] SE[illegible]

The future work of [illegible] the [illegible] work as outlined in th[illegible] service duties In addition, the work will expand naturally with the growth of the Republic and the more general application of advanced sanitary methods The General Government can secure uniform application of these methods in cities or municipalities only through the co-operation of state and local health authorities Such co operation is accomplished by the law of 1902 The conferences provided for by that law enable the surgeon-general to bring to the consideration of sanitary problems the concentrated knowledge of the most eminent sanitarians, and to secure through their co-operation uniformity of action in dealing with such problems

The annual conference called for by the act of 1902, bring the state health authorities into relation with the surgeon general and the United States Government, and in time the relations of the local and municipal health officers with their respective state boards and through the states boards with the Federal Government will be clearly defined by uniform state laws This will make a complete public health organization the like of which exists in no other country

The individual opinions and the product of their discussions in these conferences of state health officers with the surgeon general are of inestimable value in the solution of sanitary problems without in any way weakening the initiative, advisory or executive prerogatives of the Bureau of Public Health and Marine-Hospital Service

Disposal of sewage, purification of water supplies proper housing of the poor, and other subjects of moment, can be studied exhaustively by committees appointed by the Surgeon General from among the health officers of the various states

The idea of co-operation of health authorities, as fostered by the present Surgeon General, extends beyond the limits of the United States and as indicated in considering the International Sanitary Bureau, has reached the health councils of many foreign countries The elaboration of this idea, as formulated in the plans of the Surgeon General for international sanitation of seaports, will result in the eradication of the endemic foci of contagious diseases and the lessening or abolition of quarantine restrictions

The aspirations of the service—clean seaports, abolition of quarantine detention, pure water supplies, and slumless cities—may seem ideals set in the dim distant future, but in considering the marvelous achievements of sanitary science during the past five or six years one can not contend that such high ideals will not be realized, if the strenuous endeavor which has marked sanitary advancement in recent years be persevered in

As evidence of what may be accomplished in this direction, it is only necessary to consider the recent sanitary history of Habana The attitude of foreign governments and their desire for co-operation is shown by the recent request made to the Surgeon General, as chairman of the International Sanitary Bureau, by the Costa Rican Government for an expert sanitary adviser to be detailed from the Public Health and Marine-Hospital Service to supervise the sanitation of the city of Port Limon, which has been considered the worst menace to our seaport cities since the removal of Habana from the category of infected ports

Another illustration of international co-operation in matters of public health is shown to-day on the banks of the Rio Grande, where the health officers of both republics are working in harmony to make yellow fever on the Texas border a matter of history

The harmony of action existing between the Superior Board of Health of Mexico and the Public Health and Marine-Hospital Service of the United States, which has been so marked during the past year with regard to the sanitary condition on both sides of the Rio Grande, is the result, in part at least, of the First International Sanitary Convention, which was held in Washington, D C, December, 1902, referred to in another part of this article In January of the present year, through a visit of Surgeon-General Wyman to the City of Mexico, a complete understanding was effected, and a similar plan of campaign was agreed on, with regard to yellow fever, in both republics

The administration of quarantine in the canal zone on the Isthmus of Panama, will impose additional work on officers of the service The Canal Commission has requested that officers of the Public Health and Marine-Hospital Service be detailed for duty on the Isthmus in connection with quarantine and bacteriologic work This request is being complied with, and five officers have been detailed, one of whom has been made chief quarantine officer All sanitary measures, however, including quarantine, are under the general direction of the chief sanitary officer of the canal zone

A WINTER SEMESTER

LEWELLYS F BARKER, M D

CHICAGO

(Continued from page 675)

MUNICH, July 21, 1904

Following Gerhardt's example, the autopsy material from cases that have been studied previously in the clinic is thoroughly presented and discussed by Müller In his epicrisis he is less anxious to confirm a diagnosis which has been made than to emphasize diseased conditions which have been overlooked or mistakenly diagnosticated. The origin of a mistake is made clear, and the way it is to be avoided another time pointed out, the saying so frequently on the lips of Gerhardt, "*Wir hätten genauer untersuchen sollen,*" is evidently impressed on the students

The more advanced students and physicians who attend Müller's clinics are never turned empty away Notwithstanding his practice of presenting the more important clinical types so that the beginning students may possess standards in the memory and possess them thoroughly, the individual in each case is brought out and the more experienced student, therefore, is always seeing something new and having his critical powers developed It seemed to me that Müller, with all his simplicity, had the riper intelligences among his listeners ever in mind, there was always some nugget of the unusual present, though the collection of truths as a whole might be well known, the regular visitor of the clinic had daily opportunity of meeting with at least some kind of enlarging suggestion

The earmarks of earnest preparation were on every clinical lecture, one felt that the cases had not been sent in at haphazard, but that they had been subjected to rigid examination by the lecturer before presentation, and it required only a moderate familiarity with the more recent medical literature to be convinced that the latest and best articles in the bibliography had been regarded in the formation of the rounded view presented to the class Especially in the study of diseases of

STATE SUPERVISION OF PUBLIC AND PRIVATE CARE OF THE INSANE

The largest single enterprise in which the individual states in our country engage is the care of the insane The State of New York has an insane population of 23,000, cared for at an annual expense to the state of $5,000,000, and, although many states have a smaller number in proportion to their inhabitants, others have a still greater California, for instance, has 6,000 insane—a number larger in proportion to her population than any other state In passing it may be suggested that it would be an interesting subject of study to ascertain the causes of this heavy proportion of insanity in a comparatively new state

Everyone must have observed that there is at the present time a distinct renewal of public interest in this function of the state, a decided tendency to question the methods usually employed Public care of the insane is managed in several different ways California and New York, for instance, maintain all their public wards in state institutions, Wisconsin has a unique system of state subsidy to county asylums, while Illinois and most of the states divide their insane between state asylums and county poor-houses, the latter being theoretically for the chronic cases, although practically this is far from the rule It may be safely stated that the tendency is toward exclusive state care, as the state asylums are superior in equipment and in medical care, and the method is comparatively simple and compact. Adequate supervision over county institutions is difficult, if not impossible The question, however, is far from being solved by so simple an expedient as a change from county to state asylums It is clear that a malady which entails on its victims the double disabilities inflicted by insanity—mental and material helplessness—requires special safeguards, and consequently there has grown up everywhere a system more or less effective of public supervision of the care of the insane

Scotland is frequently pointed out as the country which has the most completely organized method of supervision—a method which for elasticity and effectiveness is unexcelled The Scotch system culminates in the Board of Lunacy Commissioners, consisting of five men, two unpaid and three salaried, the latter being physicians who hold their office during good behavior until the age of retirement at 62 Physicians who have served with special distinction on this board, such as Arthur Mitchell and John Sibbold, have been knighted on their retirement

Every insane person in Scotland is under the care and protection of this board, whether in a public or private institution, whether placed in a private family at state expense, or living with his own relatives The board has various deputies who act as visitors, but a large amount of personal supervision and medical examination is expected of the members themselves, as well as the usual supervisory and advisory duties which are ascribed by law to the State Boards of Charities in this country

Without going into the detail of the Scotch system, it can be seen that there is no wide difference between it and the one frequently employed in the United States, and, indeed, at the time it was adopted there is reason to believe that the framers of it received certain suggestions from our methods At that time, in the middle of the last century, the public care of the insane was a matter of much concern, and many asylums were building in our eastern states, which attracted from abroad men interested in learning American methods Yet now, while Scotland boasts an almost entirely satisfactory system, our own country is conscious of a growing dissatisfaction, not only in the condition of many individual asylums, but in the whole method of management, a dissatisfaction which expresses itself in more or less vague efforts at reform, in substituting administrative boards for supervisory bodies, boards of control for boards of charities We are not interested at this moment in judging between the relative merits of these different plans, to our mind the root of the vague distrust so generally felt in this country lies far deeper and can never be eradicated by superficial reforms

Bluntly speaking, the state political organizations of both parties have laid hold of the state institutions for the insane, and have used the appointments and appropriations for party ends, more or less extensively In some states this exploitation has not been necessary for party success, and the institutions have perhaps suffered little from it, but in others it has assumed the proportions of a plague Occasionally the institutions have been rescued by determined individual effort, as when the lamented Governor Mount of Indiana, by his personal will, pulled the asylums out of the hands of the politicians, but Indiana herself is a melancholy proof of the evanescent nature of a purely personal reform, since his successor has by no means shown the same spirit

Illinois, whose institutions were once the pride of the Middle West, has become the most conspicuous instance of the ruin wrought by political interference in public affairs which should be subject to physicians and humanitarians alone A recent series of editorials in the *Illinois State Medical Journal* has shown with indisputable clearness the fall of the Illinois institutions and the continual loss to the state of the most eminent men connected with them.

Perhaps no crueller sacrifice has been demanded by the political Moloch than that of Dr. Runge, superintendent of the St. Louis City Hospital. Although his scientific and humane management had given him a national reputation, he was compelled to resign a few months ago, and his untimely death from pneumonia, which followed almost immediately, is believed to be in part attributable to the mental strain entailed by his heroic but futile struggle against the politicians.

We may as well face the truth that there is a deep-seated evil which can not be eradicated by such superficial remedies as changing the form or the name of the power of boards, nor even by the mere passing of a merit law. The efforts of the profession and of the public must be permanently enlisted in demanding genuine devotion and expert ability in those who compose these boards. Given a board of the character which we have a right to demand—one free from interference of partisan politics—the enlargement of its scope to include private asylums would be a great gain. A system of state licensing and adequate supervision of private asylums would give the public a confidence in them which it now lacks, and would stimulate the creation of small private sanatoria, which are so rare in the whole Middle West. Our state asylums contain many free patients who could well afford to pay modest maintenance fees, and whose friends would prefer private care for them if the private institutions were at hand, and if the public did not feel a distrust in these, even greater, in some instances, than its distrust of the state institutions.

Above all, the appointments in the asylums must be made on a basis of merit, with the permanency which is found in similar positions abroad, and which is the *sine qua non* of good service. These conditions the public must understand, and these limitations the politicians must respect if the care of the insane in America is to keep pace with the general advance of humanitarian effort.

GANGRENE AS A COMPLICATION OF HEMOPHILIA.

Hemophilia is a familial blood disorder transmitted principally through females, who themselves generally escape. The first manifestations usually appear in childhood, and the affection is rare after adolescence. Death is the usual outcome. An attempt has been made to distinguish a spontaneous and a traumatic form of the disease, but it seems probable that traumatism occurs in all cases, perhaps slight and unobserved at times. Gangrene is a not uncommon complication, being attributable to the pressure exerted by extravasations of blood on the surrounding tissues. Hemorrhage sometimes takes place into a joint, and the blood may be absorbed or a panarthritis may result, with deformity and ankylosis.

The etiology of hemophilia is obscure. The hemorrhage has been referred by some to a disproportion between the relatively large amount of blood and the capacity of the vessels, by others to their small caliber and the delicacy of their walls and to fatty degeneration of the latter, and by still others to diminished coagulability of the blood. The disorder has further been considered of neuropathic and of infectious origin. A case of unusual character has been reported by Geza Faludi,[1] in which amputation became necessary in consequence of gangrene of one of the lower extremities. The patient was a boy, 6½ years old, in whom severe hemorrhage followed circumcision, probably ritual in character, in the first or second week of life. From the fourth month subcutaneous extravasations of blood began to appear in different parts of the body, at times as a result of insignificant injury, at other times independently of any obvious traumatism. In addition, there were hemorrhages from the nose and gums. During the second year a copious extravasation of blood took place into the left knee joint. At the age of 5 years, following a fall, the entire right upper extremity became swollen and in a short time cool, while the pulse was scarcely palpable. Improvement ensued under treatment, leaving, however, stiffness of the elbow joint and contracture of the fingers. Somewhat later an extravasation of blood took place into the right ankle joint and also profuse epistaxis. In the following month the child fell and, it was thought, suffered an injury to the right popliteal fossa. An extravasation of blood took place, gradually involving the entire distal portion of the extremity. The part became cool and insensitive, and large blebs formed on the surface. Finally gangrene developed, and amputation of the leg was performed at the junction of the middle and upper thirds. Conditions, however, gradually grew worse, and death took place two weeks later.

Postmortem examination disclosed, apart from the direct results of the operation, the presence of pulmonary edema, universal anemia, hemorrhagic extravasation into various muscles, bilateral hydrothorax, circumscribed adhesive pleurisy on the right, chronic circumscribed perisplenitis and perihepatitis, dilatation of the heart, fatty degeneration of the myocardium and parenchymatous and fatty degeneration of the liver and kidneys. In the joint of the amputated member the cartilage covering the astragalus and the bone itself, as well as the internal malleolus, were, in part, softened. The percentage of hemoglobin had been fifty, and the blood picture that of profound anemia. No marked change was found in the walls of the vessels. In the family history a maternal uncle had often suffered from hemorrhage, dying from this cause after extraction of a tooth. A prematurely born brother died on the thirteenth day from epistaxis.

THE TOXICITY OF BORIC ACID

The harmlessness of boric acid is assumed by all, so that it has come to be one of the most popular agents in the hands of both profession and laity, not to mention the preparers of foodstuffs As a lecturer on materia medica used to say to his classes, "Boric acid is valuable for the harm it has not done" Yet, as shown by an article on another page,[1] boric acid has, under exceptional conditions, been a cause of death in several instances If we put together the facts brought out by Best and the results obtained by Wiley in his series of experiments on the effects of boric acid in food, we have basis for a fair conclusion as to the exact limits of safety of boric acid

Wiley found that boric acid in quantities of four or five grams per day continued for some time results in most cases in loss of appetite and inability to perform work of any kind Four grams per day may be regarded as the limit of exhibition, beyond which the normal man may not go, a majority of normal men can take three grams per day for a somewhat protracted period and still perform their duties They commonly felt injurious effects from this dose, however, and it is certain that the normal man could not long continue to receive three grams per day One-half gram per day for 50 days produced in some instances somewhat unfavorable effects, so that it would seem that while this amount can be taken for a limited period of time without much impairment of health, its protracted use would not be safe It is estimated that a person eating butter and meat, both treated with boric acid as a preservative would receive, perhaps, as much as one-half gram per day If, however, the diet were varied, this amount would be reduced, and no harm might result in a very long time From this it may be concluded that occasional use of foods preserved by ordinary quantities of boric acid is not likely to cause any appreciable injury, but a dietary composed solely of such foods might, in the course of some weeks, cause much disturbance There seems to be particular danger of renal injury from the boric acid in its elimination, for about 80 per cent of the boric acid escapes in the urine

When very large quantities of boric acid enter the circulation in a short space of time, however, there is profound intoxication which, in five reported cases, has led to death There is no record of fatal poisoning from boric acid administered internally, all these cases having resulted from absorption from wounded surfaces The packing of wound cavities or the vagina with a solid mass of boric acid seems to be a not uncommon practice, although as a method of treatment it may be open to question It certainly is a dangerous procedure, whatever its therapeutic value, for, although large numbers of patients may show no harmful effects, yet it is evidently capable of causing serious and even fatal intoxication This procedure is based on the assumption that boric acid is non-toxic in any quantity, which is not true Care must also be used in irrigating large cavities with boric acid, since serious symptoms may result from the amount of it that may be absorbed from an empyema cavity or a lumbar abscess

PSEUDO ASCITES

Although free fluid in the peritoneal cavity is ordinarily recognizable with ease, other conditions may cause similar symptoms On the one hand, such fluid may, in consequence of adhesions or of gaseous distention, give rise to an asymmetrical area of dullness, while its mobility on change of position may be interfered with On the other hand, obese or edematous abdominal walls yield a sort of undulation on percussion, while properitoneal abscesses or lipomata, tumors of the intestinal wall, or deeply seated abdominal neoplasms or cystic tumors of the abdominal viscera may be a source of error in diagnosis The greatest difficulty of differentiation, however, is encountered in connection with a condition described by Dr L Tobler[1] as pseudo-ascites, which is dependent on the presence of fluid in distended small intestine with an elongated mesentery The affection was observed in children between two and one-half and nine years of age, and especially in girls It is characterized by gradual increase in the size of the abdomen, in connection with continued, intermittent or recurrent diarrhea, lasting for months or years The child, which may likewise be rachitic, becomes debilitated and emaciated It may exhibit also enlarged lymphatic glands or tuberculosis of bones or lungs There is, as a rule no fever, and subjective symptoms are usually wanting or there may from time to time be complaint of abdominal pain

As a rule the abdomen itself is distended, its cutaneous covering stretched shining or scaly, the umbilicus obliterated, the veins distinct In the standing posture the abdomen is not rarely pendulous, forming at times a transverse fold at the symphysis, and frequently the resistance is increased in the lower portions Variations in the state of the abdomen take place, and distention may be replaced by relaxation with a sense of doughy resistance in the hypogastrium, and at times a splashing sound may be appreciable Undulation may be present in either event, the most distinct and shortest wave impulse being obtained when the area of dullness is considerable and symmetrical and the tension of the abdominal walls is marked The impulse is not appreciable above the level of dullness as it is in the presence of true ascites The percussion-dullness varies in extent, position, outline and mobility in individual cases and in the same case at different times

The condition must be differentiated especially from chronic exudative peritonitis, particularly of tuberculous origin In both the physical signs develop gradually but the latter is likely to be attended with fever, severe persistent pain and uninterruptedly progressive aggravation, while in the former the signs are variable, with remissions and exacerbations. The former is further characterized by diarrhea, the stools being numerous, often copious and presenting catarrhal features, while the dejections of tuberculous peritonitis are few and thin. Although the physical signs are suggestive of the presence of fluid free in the peritoneal cavity, such a condition is not found on operation or at autopsy. The peritoneum is, as a rule, entirely uninvolved, and solid and cystic tumors are wanting. The phenomena are best explained by the presence of fluid in portions of the intestinal tract whose tone is impaired as a result of catarrhal conditions, and which are at times displaced downward in conjunction with elongation of the mesentery.

THE PHILIPPINE OPIUM REPORT

The plan recommended for the regulation of the opium traffic in the Philippines, as reported, is one that commends itself. While the government controls the sale it makes no profit, which relieves us from the reproach justly made against the British Indian Government for its action in this matter. The total abolition of the sale in three years which is provided for will, it is to be hoped, be successfully carried out. Wherever the Chinese abound the opium problem exists, but unfortunately, the evil extends from them to other races. The trouble that the Japanese Government has had with it in Formosa possibly indicates somewhat the difficulties to be met with in the Philippines.[1] But the success they have attained is encouraging for our own authorities. It will be a pity if we can not manage this matter as satisfactorily as do the Japanese.

CUBAN SANITATION

It is generally understood that the arrangements by which the independence of Cuba was secured included provisions for adequate sanitary measures being adopted by the Cuban authorities to prevent danger of transmission of disease to this country. It appears that difficulties have been experienced, that local authorities refuse to co-operate, and that in some of the interior cities the conditions are far from satisfactory. It is unfortunate for Cuba if it has failed to make provision for central control of sanitation or for such measures as would compel the local authorities to do their duty. If an epidemic of yellow fever or any other tropical infection should be transmitted to us from infected points it would be difficult for the Cuban Government to escape the charge of bad faith and treaty violation. Of course, the greatest danger lies in the principal seaports, and we believe that Havana at least, under the able administration of Dr. Finlay, is in good sanitary condition. There are other places and possibilities, however, which he can not control, and it is to be hoped that whatever is lacking at the present time in other localities will be remedied. Cuba owes it to herself, as well as to this country, to see that the wretched sanitary conditions of the past be not again allowed to develop.

A FACTOR IN THE ANEMIA OF UNCINARIASIS

The impetus given to the study of tropical diseases in this country by the acquisition of the Philippine Islands has led to the recognition of the fact that many of the so-called tropical diseases are to be found in the semitropic regions of North America. One of the diseases of this character which is probably very widely distributed in the Southern States, is uncinariasis. The uncinaria has been widely studied, both in the tropics and in the temperate zone, where it produces the so-called tunnel anemia or miner's anemia. A fact which has often been commented on in the various published studies, is the discrepancy which often occurs between the number of parasites and the severity of the anemia. A very severe anemia may exist, and yet very few worms may be present in the intestinal tract. Some recent work of Loeb and Smith[1] seems to explain the manner in which a few worms may cause a grave anemia. These writers have shown that there is present, in the anterior end of the parasite, a substance which has, to a marked degree, the power of inhibiting the coagulation of the blood. It has been known for some time that one worm often makes a series of punctures, and this being the case, it is easy to imagine a considerable loss of blood from each of these if coagulation be retarded.

LIGATION OF THE EXTREMITIES AND AUTO TRANSFUSION

Ligation of the extremities by means of elastic bandages applied not too firmly to the thighs and arms has long been known and practiced as a measure for the control of hemorrhage, particularly from the lungs, the object being to check the return of venous blood without interfering with the arterial supply. As a result, the blood pressure falls and bleeding ceases. The opposite conditions are brought about by the application of the bandage from the periphery in a proximal direction, constituting the procedure that has been designated autotransfusion. Dr. W. Plaskuda[2] reports the results of an investigation undertaken for the purpose of determining experimentally the amounts of blood that can be removed from or supplied to the circulation under the circumstances detailed, and also the state of the blood pressure in the free vessels. He found that from three-quarters of a liter to one and one-quarter liters of blood can be removed from or conveyed to the trunk and the head by ligation or bandaging of all four extremities by means of rubber bands. Marked stasis in three extremities lowers the blood pressure about 20 millimeters of mercury (14 per cent.). The results are somewhat variable and uncertain in nervous individuals. Occasionally, however, states approaching collapse develop in conjunction with sudden and more marked reduction in pressure, but these disappear rapidly when the bandages are released. When anemia is induced artificially in several extremities the blood pressure is decreased, apparently as a result of nervous rather than of mechanical influences.

BAD SPELLING BY PHYSICIANS

Among the general criticisms on medical education in this country, one of the chief is that based on lack of preliminary educational acquirements This has been the subject of many rather severe comments, both in the medical and secular press, as well as in the reports of the state examining boards like that of Pennsylvania One of the more notable defects of candidates is that of the inability to spell properly, and this is apt to be taken by some as an index of general illiteracy Nothing appears worse than bad spelling, and yet it seems to be a fact that deficiencies in orthography are more common at the present time, in spite of all the advances that have been made in educational standards, than they were a generation or so back There must be some defect in modern school methods, and the conviction that this is so appears to be growing It is possible that the abandoning of oral and syllableizing methods of teaching spelling is largely responsible The modern plan seems largely to be to educate a visual memory, and this is not necessarily by any means the characteristic of the highest mental development An experienced teacher remarked that she had noticed that the good mathematicians among her scholars were the poorest spellers We do not know how general this observation is but it is at least significant, and it is possible as the *Maryland Medical Journal* admits, that one may be an accomplished physician and yet a bad speller We fear that instances of this kind will be more numerous than they should be among physicians of the present generation We have no desire to excuse bad spelling by physicians, but we would like to say a word in favor of a possible reform in pedagogic methods which may be more or less responsible Spelling reform of this particular kind, or rather reform of the teaching of spelling, is hardly a medical subject, but it has medico-psychologic bearings that are worthy of attention

---

THE INSANITARY FLAT

Judging from the records of the building department of the city of New York, according to a lay paper, only sixty private houses were erected last year in the whole of Manhattan Island, while the number of apartment buildings erected during the same period reached into the thousands This record is repeated, to a greater or lesser extent, in all of our large cities, and the building of flats and tenement houses extends also to the suburbs We are becoming less and less a home-dwelling people, and are crowding more and more into what the paper quoted calls "human honeycombs" This may be a normal phase of social evolution The fact indeed that it occurs so extensively supports this view It has, however, its threatening side It is a factor in the much-discussed race suicide which some consider threatening Children are not favored in these buildings nor do flats furnish the ideal conditions for their welfare It is mainly in the lower grade of tenements and in the slums that children abound, and their condition there is a very serious urban sanitary problem There are, however, other hygienic disadvantages in this concentration of humanity, such as the questions of ventilation and sunlight, which are often seriously restricted and embarrassed in these tenements It is not in the highest-priced and most luxurious of this class of dwellings that we find the most of these defects, as the rich can provide for themselves, but in the cheaper ones—those which are occupied by the great mass of workers of the intermediate class, the clerks, the professional men, the better class of mechanics The housing of the poor is a perennial question for philanthropists, but the housing of the middle class has hardly been considered by them, notwithstanding the fact that in our large cities it is becoming more and more a serious question We have already called attention to this subject, and showed the fearfully insanitary conditions that must exist as regards sunlight and ventilation even in some of the higher-priced flats We can not expect a healthy people to grow up under such conditions, and if we escape physical degeneration, with the growing tendency toward flat building in our centers of population, it will be through a special Providence—certainly not from causes that we can rationally foresee with our present lights

---

THE PRIMARY SEAT OF INFECTION IN FATAL CASES OF TUBERCULOSIS

It is a matter of no small difficulty to determine the primary seat of infection in many cases of tuberculosis The age of the lesions can not always be accurately estimated from either their intensity or their extent The question at issue has, however, distinct practical significance, inasmuch as the prophylactic measures to be instituted must be based on the decision reached With the view of establishing the relative frequency with which the abdominal and the thoracic viscera respectively are invaded primarily, Dr J Odery Symes and Dr Theodore Fisher[1] have analyzed the postmortem records of 500 cases in which death took place as a result of tuberculosis They found that, of 102 cases in patients under the age of 12 years, 12 appeared to be definitely abdominal in origin and 57 definitely thoracic in origin, while in 24 there was doubt as to whether the origin was abdominal or thoracic The primary lesion, it is thought, was possibly situated in bones or joints in 4 cases, in the skin in 1, in the tonsil in 1, while no focus that could be considered primary was found in 3 Between the thirteenth and twenty-fourth years there were 8 cases apparently primarily abdominal, 31 primarily thoracic and 3 of doubtful origin, while between the twenty-fifth and thirty-sixth years the proportion of cases primarily abdominal to those primarily thoracic was as 1 to 9 66, and between the thirty-seventh and the forty-eighth year as 1 to 9 25 Between 48 and 60 there was no case in which the disease was primarily abdominal and above 60 there was but 1 of this kind and 7 in which the disease was primarily thoracic In three cases the kidney appeared to be the organ first affected and in two the epididymis In two fatal cases of Addison's disease the adrenal glands alone were the seat of tuberculosis From the foregoing observations it appears that during the first twelve years of life tuberculous infection by way of the air passages is four times as common as that by way of the alimentary canal, and the ratio is about the same during the second twelve years, but deaths in hospitals above the age of 12 years can hardly be considered as representing the average causation of death from varieties of tuberculosis for the whole population above that age, because cases of tuberculosis of the lungs are more chronic at that time than at an earlier period of life, and they are not usually admitted to ordinary hospitals Notwithstanding the exclusion of cases of chronic pulmonary disease from hospitals, the proportion of cases of abdominal to those of thoracic tuberculosis in the institutions from which the data were obtained was exceedingly small after the age of 24

Medical News.

ALABAMA

Personal.—Dr Marvin W Dupree, Mount Vernon, assistant at the State Hospital for the Insane, has resigned and taken up practice at Athens

Smallpox.—Dr William C Wheeler Huntsville, health officer of Madison County, reports that there are about 10 cases of smallpox at New Hope, but that they are thoroughly isolated.

Acquitted of Murder—Dr John B Farley, of Farley, Madison County, charged with the murder of Davis Johnston, was acquitted, August 29, after a trial lasting two days He claimed that he acted in self defense

Statue to Dr W E B Davis—The memory of the late Dr William E B Davis Birmingham, is to be perpetuated by the erection of a monument by the Southern Surgical and Gynecological Association, of which Dr Davis was the originator The statue is being made by G Moretti, and will be in bronze, 7½ feet high, standing upon a granite pedestal 9½ feet high He has made an indemnity contract to have the statue ready by December 1 that it may be unveiled at the coming meeting of the association

ARIZONA

Typhoid at Douglas.—It is alleged that there are more than 75 cases of typhoid fever in Douglas, and that the condition of the city is inexcusably unsanitary

Appointed Examiner—Dr Charles H Jones has been appointed a member of the Territorial Board of Medical Examiners, vice Dr William Duffield, Phoenix, resigned to become superintendent of public health

Hospital at Bisbee—Ground has been broken for the new Calumet and Arizona Hospital at Bisbee The building will contain four wards, private, operating, sterilizing and anesthetizing rooms, and laboratories, and will accommodate 50 patients

Plague Only a Rumor—On account of startling announcements regarding 'black heart" and "bubonic plague" in and around Bisbee, acting assistant surgeon A. L Gustettee, U S P H. and M H Service, has made a thorough investigation of the situation and reports that there are absolutely no grounds for the rumors, and that there is no epidemic disease prevalent in Bisbee

CALIFORNIA.

Personal.—Dr Rupert Blue San Francisco, has been elected president of the Public Health Commission of California.——Dr Joseph D Davidson, Fresno, returned from Europe, August 24

Plague on Steamer—The *Coptic*, which arrived at San Francisco from the Orient, August 29 was sent to the quarantine station on account of the death of a Corean passenger near Honolulu from bubonic plague

Kitasato in America.—Dr S Kitasato, president of the Institute for Infectious Diseases, and of the Serum and Lymph Institutes of the Imperial Government of Japan, arrived in San Francisco, August 29, en route to the Congress of Medicine at St Louis

Made Democratic Elector—Dr William M S Beede, Stockton, a member of the American Medical Association, Medical Society of the State of California and San Joaquin County Medical Society, who was United States consular surgeon at Hong Kong from 1896 to 1900, has been nominated as a democratic presidential elector

Medical Arrangements at Conclave—The medical arrangements at the triennial conclave of Knights Templar, at San Francisco, were excellent Dr Curtis G Kenyon was chairman of the committee, which maintained headquarters at the Palace Hotel, and an emergency hospital at the Mechanic's Pavilion, a staff of 40 mounted physicians in the parade, and a complete ambulance service

For the Sick.—St Vincent Hospital and Medical Association has been incorporated at San Francisco with a capital stock of $75,000 by Drs Joseph P Le Fevre, John C Newton, and others ——The Southern Pacific Railway will establish a hospital at Dunsmuir——The Los Angeles College Clinic Association has been incorporated without capital stock, by Drs Joseph Kurtz, William LeM Wills, H. Bert Ellis, William D Babcock and Granville MacGowan The purposes of the association are to establish and conduct a hospital and dispensary for the treatment and care of the indigent sick and injured persons, to treat emergency cases and such other sick and injured persons who may be or become a charge upon the city, to conduct and maintain an institution for instructing, educating and training men and women in the sciences of medicine and surgery

DELAWARE

Nominated for Governor—Dr Joseph H Chandler, Centreville, has been nominated for governor on the Republican ticket

Ohio Hospital Incorporated.—Papers of incorporation have been filed in Wilmington for the Marion (Ohio) City and County Hospital Company, with a capital stock of $50,000

The Chandler Dinner—At the twelfth annual dinner to the medical profession, and the Dr Chandler Medical Club of Delaware, held at the home of Dr Joseph H Chandler, in Centreville, the address of welcome was delivered by Dr Swithin Chandler Philadelphia, papers were read by Drs Hobart A Hare, William L. Rodman, John G Clark, John H. Musser, Henry Boenning, and W M L. Coplin, Philadelphia, a paper was read also by Dr A. Robin, Wilmington, and a poem by Dr James H Morgan, Wilmington.

DISTRICT OF COLUMBIA

Ordered to Chair of Tropical Diseases.—Medical Director Phillips A Lovering, U S Navy, has been ordered from the Asiatic Station to Washington, to assume the new chair of tropical diseases, in the Naval Medical School

The Year's Deaths—The mortality per 1,000 in the District was 20 14 for 1903, while for 1902 it was 19 99 The increase occurred during January, February, March, November and December, was altogether among the white population, was chiefly between the ages of 65 and 69, and was chiefly due to diseases of the nervous and circulatory systems and to violence.

Woodward Not Convinced.—Dr William C Woodward, health officer of the District, despite the suggestion of the Agricultural Department that copper sulphate be used in the public reservoirs as a disinfectant, is not convinced, believes the matter is still one of experiment, and is not sure that instead of typhoid fever prevention, copper poisoning might result from the use of this substance in the drinking water supply of Washington

GEORGIA.

Personal.—Dr Ludwig Amster, Atlanta, has returned from Europe——Dr E G Adams, Greensboro, has been appointed resident physician at the Presbyterian Hospital, Atlanta

Fined for Cocain Selling—Dr Millard B McAfee, Atlanta, charged with the illegal sale of cocain to negroes, who admitted on trial that he had written 80 prescriptions for cocain in a single day, was fined $100 and bound over to the city court under a $200 bond, August 23

Tuberculosis Board Named.—On August 31 the governor named as a medical commission on tuberculosis From the state at large—Drs Charles Hicks, chairman, Dublin, Louis H Jones, Atlanta, Ernest P Ham Gainesville, Palarmon T Hillsman, Albany, Joseph R. Burdette, Tennille, Pryor W Fitts, Greenville, S A Brown, Dalton L. G Hardman, Commerce, Loyd J Belt, Millen, and John L. Walter, Waycross From the congressional districts—1, Dr Eugene R Corson Savannah, 2, Dr O B Bush, Camilla 3, Dr Alexander

Mack, Hawkinsville, 4, Dr Henry R. Slack, La Grange, 5, Dr Bernard Wolff, Atlanta, 6, Dr George L Alexander, Forsyth, 7, Dr Thomas R Garlington, Rome, 8, Dr Henry E Thornton, Hartwell, 9, Dr Jefferson Davis, Toccoa, 10, Dr Thomas D Coleman, Augusta, and 11, Dr S E Sanchez, Barwick

ILLINOIS

Personal—Dr Amos F Moore, Dixon, has been appointed district surgeon for the Chicago and Northwestern Railway, vice Dr Henry E Paine, deceased

Brutal Assault—Dr Henry E Lightfoot, Carbondale, was attacked by unknown individuals, August 20, struck on the head with a blunt instrument and rendered unconscious

Smallpox—At Belleville 9 new cases were reported, September 8 Strict quarantine regulations were ordered to be maintained ——Centralia has had 13 cases, and believes the spread of the disease has been checked

Arranging for State Society—The profession of Rock Island is already organizing for the comfort and entertainment of the Illinois State Medical Society, which is to meet in Rock Island in May next Dr Carl Bernardi has been made chairman of the committee of arrangements, Dr George G Craig, vice chairman, and chairman of the reception committee, and Dr Frank H First secretary treasurer Dr William H Ludewig is chairman of the committee on advertising and invitation, Dr J R. Hollowbush, entertainment, Dr B F Hall, hotels, lodgings and halls, Dr St Elmo M Sala, exhibits, Dr Joseph D Silva, finance, Dr Emily Wright, entertainment of ladies, and Dr Shelley B Hall, transportation

Chicago

Semon in Chicago—The Chicago Laryngological and Climatological Society gave a dinner in honor of Sir Felix Semon, at the Chicago Club, September 15

A Correction—Dr Vida A Latham writes that she was elected vice president of the American Microscopical Society, and not secretary, as stated in THE JOURNAL of September 3 Dr Robert H Wolcott, of the University of Nebraska, was elected secretary

Children Have Smallpox—The spread of smallpox among children is causing grave concern to the department of health On September 10, four children were taken to the Isolation Hospital, and one little patient died there There are now 15 patients in the hospital

Personal.—Dr Olander E Wald has been appointed chief surgeon of the Bethesda Hospital ——Drs Arthur D Bevan and James Chvatal have been nominated on the committee to represent Chicago at the Louisiana Purchase Exposition, on "Chicago Day," October 8 ——Dr Joseph Z Bergeron has returned from Europe

Death-Rate Continues Low—For the week ended September 10, 443 deaths were reported 48 less than for the previous week, and 61 less than for the corresponding week of 1903, the respective annual rates per 1,000 being 11 98, 13 27, and 14 02 Acute intestinal diseases caused 97 deaths, consumption, 49, violence, 45, and heart disease, 35

KENTUCKY

Smallpox has appeared in Mayfield, where there are four cases in one family, and among the negroes near Pembroke, where four cases have been discovered

Stringent Rules Adopted—The State Board of Health has adopted stricter rules, requiring examination of physicians of other states desiring to practice in Kentucky, limiting medical colleges to cities of 50,000 or more population, prohibiting medical colleges from having more than one school term a year, and requiring preliminary examination of all prospective medical students

One Year's Deaths in Louisville—Dr Maverell K. Allen, health officer of Louisville, reports that during the year ended August 31, 4,092 deaths occurred, a death rate of 17 56 per 1,000 The rate among white people was 15 2 per 1,000, and among the colored population, 27 4 Tuberculosis caused 562 deaths, pneumonia 467, heart disease, 284, violence, 182, Bright's disease, 167, cancer, 125, apoplexy, 145, typhoid fever, 112, and meningitis, 100 September, June, July and August were the months of greatest mortality

Personal—Dr Joseph M Ferguson, South Carrollton, has been appointed second assistant physician at the Western Kentucky Asylum for the Insane, vice Dr James W Stephens, transferred to the Central Kentucky Asylum Lakeland ——Dr William N Offutt, Lexington, has been made captain and assistant surgeon of the Second Kentucky Infantry, vice Dr William J Foley, Lexington, made regimental adjutant ——Dr James M Mathews, Louisville, has been appointed a member of the International Commission of Awards at the World's Fair, St Louis

MARYLAND

Nominated for Congress—Dr Richard S Hill of Prince George's County has been nominated for Congress He is a graduate of Georgetown University Medical School, and is at present a member of the Maryland House of Delegates

Answer to Mandamus Suit—In its answer to the suit for mandamus brought against it by Dr Campbell F Flautt of Baltimore, the State Board of Medical Examiners denies that Dr Flautt is entitled to a license to practice, and avers that on two occasions (in 1901 and 1902) he failed to pass the examination While admitting that Dr Flautt graduated from the Baltimore Medical College in 1901, it denies that he was a physician or surgeon lawfully practicing in Maryland prior to Jan 1, 1898 It claims it has no authority to issue a license to persons whose sole right to practice medicine rests on the irrelevant fact that they "had practiced medicine and had in their professional capacity and within a year prior to Jan 1, 1898, treated 12 persons" The only persons entitled to a license to practice medicine in Maryland under Section 72, Article 43, of the code, it is claimed, are those who have passed the required examinations, and physicians from other states

Baltimore

Personal—Drs Hugh H Young, William A Fisher and Richard H Follis have gone on a week's trip to Manassas, the Valley of Virginia, and the University of Virginia

Want City to Maintain Beds—A committee from the Baltimore University Hospital called on the mayor, September 1 to request that the city contract with that institution for free beds for public patients The Supervisors of City Charities, to whom the matter was referred by the mayor, have not maintained city beds in that hospital for a considerable time

Honor Dr Remsen—The Society of Chemical Industry, meeting in New York City last week, paid a high tribute to Dr Ira Remsen, President of Johns Hopkins University, by awarding its medal to him This medal was founded in 1896, and is awarded every two years for conspicuous service rendered to applied chemistry, by research, discovery, invention, or improvements in processes Probably the most noteworthy discovery made by Dr Remsen was saccharin, discovered in his laboratory in 1879 His "Chemistry" has been translated into German, French, Italian and Japanese, and is used in colleges in all those countries, and in nearly every college and university in America, and his "Organic Chemistry" is also well known

NEBRASKA

Personal—Dr George W Ira, for eighteen years agency physician at the Santee Indian Reservation, Knox County, is about to move to Lynch, Boyd County

Hospital for Falls City—Drs Frank C Wiser and Isaac M Houston, Falls City, have equipped a 28 room building as a hospital, to be known as Mercy Hospital, and to be open to all reputable practitioners

Dr Orr Married.—On September 7, at Grinnell, Iowa, Miss Grace Douglass of that city was married to Dr H Winnett Orr, Lincoln, editor of the *Western Medical Review* They will be at home at 1114 H Street, Lincoln, after October 1

Fined Because Not Registered—Dr Nils P Hansen Oakland, arrested on charges filed by Isaiah Lukens Tekamah, for the illegal practice of medicine, was found guilty as charged, and fined $50 He had neglected to file his registration with the county clerk, as required by law

NEW YORK

Typhoid at Jamestown—An epidemic of typhoid is reported from Jamestown

Buffalo Voyagers—Dr A L Benedict has sailed for a short sojourn in Europe ——Drs W Scott Renner and Frederick J Barrett have returned from Europe

Hospital Charges Dismissed—The State Board of Charities has dismissed the charges against the physicians of the Sydenham Post Graduate Course and Hospital on the grounds that this institution does not receive public funds, and, therefore can not be under its jurisdiction

Hydrophobia at Ithaca—About two weeks ago a rabid dog ran about in Ithaca, biting several animals The veterinary department of Cornell University inoculated a number of guinea pigs with the saliva of the rabid dog, and successfully A number of people have been bitten by these animals, but so far only three cases of hydrophobia have developed

Incubators at Coney Island—Because of the charges recently made against the baby incubator system at the St Louis Fair, Arthur M Bishop president of the New Jersey State Society for the Prevention of Cruelty to Children, in company with several superintendents of state and local institutions, inspected the incubators at Coney Island They expressed themselves as being satisfied.

High July Death Rate—The State Department of Health reports a total of 12,061 deaths for July, equivalent to an annual death rate of 18.5 per 1,000 The deaths were 601 above the average of July for the last five years The increase was mainly due to four causes Acute diarrheal diseases, diseases of the digestive system, diseases of the nervous system and violence Of all deaths, 53 per cent were of children under five

New York City

Sale of Carbolic Acid Restricted—An amendment to the sanitary code has been adopted restricting the sale of carbolic acid in concentrated form and compelling druggists to dispense a 5 per cent solution only

Hebrew Convalescent Home—Initial steps have been taken toward the organization of the Hebrew Convalescent Home Association It is proposed to buy a tract of land in Westchester County for the erection of an edifice for this purpose

A New Office for the Bronx.—The rapid increase of population in this locality and the recent typhoid scare have made more effective sanitary work necessary, and Dr Charles F Spencer has been appointed chief inspector of contagious diseases in the district

Contagious Diseases—There were reported to the sanitary bureau for the week ending Sept 3 1904, 200 cases of diphtheria, with 28 deaths, 70 cases of scarlet fever, with 5 deaths, 57 cases of measles, with 3 deaths, 334 cases of tuberculosis, with 162 deaths, 118 cases of typhoid fever, with 13 deaths, and 10 deaths from cerebrospinal meningitis

Personal.—Dr James C Hallock, a retired physician, was assaulted and received a serious scalp wound while sitting in Prospect Park ——Dr Martin Auspitz, while driving a patient home from his office, collided with an electric car, the patient sustained a fracture of the skull, a boy stealing a ride was killed and Dr Auspitz was painfully injured

OHIO

Accidents—Dr Oliver A Price, Cincinnati, while visiting in Columbus, August 28, was thrown from an electric car, sustaining a compound fracture of the right leg, and dislocation at the ankle joint ——Dr Le Grand Gribble, Pomeroy, was accidentally wounded while shooting in Bedford Township, August 30

Medical Library for Akron.—In memory of his father Dr H M Fisher of Akron, his son Frank T Fisher, New York City, has donated to the Summit County Medical Society his father's medical library to become a part of the Akron public library, and to be known as the "H M Fisher Medical Library" Mr Fisher promises in addition to give $100 a year for the purchase of new books

Cincinnati Personal.—Dr Charles A L Reed, who has spent the last three months in Europe, has returned home ——Dr Earl H Bruns, resident surgeon of Cincinnati Hospital, has passed his examination for entrance to the Medical Corps of the Army, and will leave for Washington October 1, for an eight months' course in the Army Medical School ——Dr and Mrs J C Culbertson have returned from Georgian Bay

Staff for New Hospital.—The following have been named as the staff for the new Springfield Hospital, which is to be opened next month Surgical—Drs Read L. Bell William B Patton, Robert C Rind and Louis L Syman, medical—Drs Jay D Thomas, George F Brubaker Clinton M Hiestand, Stanley R. Hutchings, Charles W Evans and Noah Myers, eye and ear—Drs Charles L Minor and John C Easton, obstetrical—Drs John M. Buckingham, William A Smith, and Clarence S Ramsey, diseases of children—Dr D King Gotwald, nervous diseases—Dr Clarence H Kay genitourinary diseases—Drs Henry Baldwin Jr and Ira E. Seward, pathologist—Dr Frank P Anzinger, skiagrapher—Dr Emory F Davis, and consulting staff—Drs Ezra C Harris, John P Dugan, Bennetta D Titlow, Allen H Vance and D Walter Spence

OREGON

Personal.—Dr James F Bell has been appointed to fill the place in the Portland Board of Health made vacant by the death of Dr William H Saylor ——Dr Thomas M Henderson, Pendleton, has been elected coroner of Umatilla County

Medical Building for Willamette—There is urgent need for a special building for the medical department of Willamette University, Salem, and it is estimated that the building will cost $17,000 Already two subscriptions, one of $2,500 and the other of $1,000 have been made toward the building fund

Medical Board Election.—At the annual meeting of the State Medical Board the following officers were elected President, Dr Walter E Carll, Oregon City, Dr Byron E Miller, Portland, secretary, and Dr Angus B Gillis, Salem, treasurer Dr Andrew C Panton, Portland, was appointed a member vice Dr William H Saylor, deceased

Oregon State Medical Society—The thirty first annual meeting of this society was held in Portland August 30 and 31 About two hundred physicians were in attendance and the program was of unusual interest In addition to the papers presented by the profession of the state, Dr Charles H Mayo, Rochester, Minn, presented a paper on "Cancer of the Large Bowel" Dr Walter C Williamson, the president, entertained the members of the society at an informal reception and smoker at his residence, and the City and County Medical Society of Portland were hosts at a banquet at the Hotel Portland on the second evening The following officers were elected Dr George F Wilson, Portland, president, Drs Mae H Cardwell, Portland William H Boyd, Salem, and William L. Wood, Portland, vice presidents, Dr Luther H Hamilton, Portland, secretary, Dr Jessie M McGavin, Portland, treasurer, and Drs R C Coffey and Henry W Coe, Portland councilors Dr Kenneth A J MacKenzie, chairman of the committee of arrangements for the reception of the American Medical Association, to be held in Portland in 1905 has named the following committee to assist him in his work Drs Henry W Coe, William Jones Andrew C Smith George F Wilson, Andrew J Giesy and Ernest F Tucker, all of Portland

PENNSYLVANIA

Dr Lampman's Will.—The will of the late Dr John S Lampman, Wilkesbarre, devises the entire estate, valued at $39,500, to his wife, and on her decease, to his two sons

Reception to Surgeon General Weaver—The physicians of Norristown gave a reception and banquet, September 6, in honor of Dr Joseph K. Weaver, who was recently appointed surgeon general of the National Guard of Pennsylvania

Typhoid Still Dominant—Of 21 cases of contagious diseases reported at Pittsburg, September 4 and 5, 15 were typhoid fever, and of 16 cases reported September 6, 7 were of this disease In the week ended August 27, 73 of the 113 deaths were due to typhoid fever

Texas Fever—A large number of the cattle received from the west in the stockyards of Chester and Lancaster counties have been found to have Texas fever, and a large number of deaths have occurred The disease has spread rapidly throughout these counties, and is recently reported in Berks County also

Personal.—Drs Frederick H. Bloomhardt and Charles I McBurney have resigned from the Altoona Board of Health ——Dr Daniel Webb has been appointed to the surgical staff of Lackawanna Hospital, Scranton, vice Dr Alexander J Connell, chief-of staff, resigned, and Dr Addison W Smith has succeeded Dr William G Fulton, who has been made a trustee Dr Reed Burns has been appointed chief of the surgical staff

Philadelphia.

Dr Eshner Married.—Announcement cards have been received of the wedding of Dr Augustus A Eshner to Miss Julia Friedberger, which occurred September 7 Dr and Mrs Eshner will reside at 1019 Spruce Street

Personal.—Dr Alexander C Abbott, chief of the bureau of health, and professor of hygiene in the University of Pennsylvania, will deliver the inaugural address at the formal opening of McGill University, Montreal, September 12 ——William Krusen has returned from Europe

Health Report—Typhoid fever still prevails throughout the city, but the number of cases reported for the week was lessened The death rate from the disease, however, is slightly higher There were 100 cases of typhoid, with 14 deaths, reported for the week, as compared with 104 cases, and 10 deaths, for the preceding seven days This city has more typhoid fever than any of the other large American cities There were 400 deaths reported for the week ended September 10, as compared with 371 for the previous week, and 370 for the corresponding period of last year, and 379 for the corresponding week of 1902

August Hospital Work—During August there were admitted to the wards of the Pennsylvania Hospital 342 patients and 2,730 emergency cases were treated in the receiving wards There were 5,018 cases treated in the out patient department, and the total visits made to the out patient department numbered 7,506'——In the Germantown Hospital 121 patients were admitted, and 1,529 patients were treated in the dispensary ——The Methodist Hospital admitted 69 patients to the wards and 830 patients in the different dispensaries The total visits made to the dispensary numbered 3,184——In the Women's Hospital 1,549 patients were treated in the different clinics——There were 184 patients admitted to the wards of St Agnes' Hospital, and 696 new cases and 2,582 old cases were treated in the various dispensaries——In St Mary's Hospital 171 patients were admitted and 3,054 patients were treated in the dispensary

GENERAL

Beri-Beri.—According to a newspaper report, the bark *Foo Sucy* from Honolulu, which arrived at Delaware breakwater recently, was found to have several cases of beri beri on board One man died at sea from the disease The vessel was quarantined

Medical Missionaries Wanted—Mrs B F Witt, Dayton, Ohio, secretary of the Woman's Missionary Association, asks us to call attention to the fact that the above association is in need of medical missionaries for Canton, South China Either man or woman, married or single, will be accepted if found satisfactory A woman physician is also needed for Jubbulpore, Central India The position is under the auspices of the Methodist Episcopal Woman's Foreign Missionary Society Further particulars can be obtained by communicating with Miss Nettie M Hyde, Clifton Springs, N Y

Professor Orth.—Dr Johannes Orth arrived in New York, September 5 en route to St Louis He is to be entertained at the White House by the President, September 27, and a dinner will be given him, probably in New York by his former pupils about October 3 Dr Orth is professor of general pathology and pathologic anatomy at Berlin, and is also dean of Berlin University He was formerly assistant to Rindfleisch and later to Virchow, until called to be professor of general pathology at Göttingen in 1878 He succeeded to Virchow's chair in Berlin and also to the editorship of *Virchow's Archiv*

The Weightman Fortune—The *Medical News*, in referring to the death of William Weightman, head of the firm of Powers & Weightman drug manufacturers of Philadelphia has revived the story of how the greater part of the immense fortune of the firm was derived from the sale of quinin during the Civil War At that time, the only two firms in the country making quinin from Peruvian bark were Powers & Weightman and Rosengarten & Sons, both of Philadelphia The regular price of the drug at the beginning of the war was $2 10 an ounce, and south of Mason & Dixon's line it was often sold as high as $15 00 an ounce but the Philadelphia firms, although having a monopoly of the drug, never sold it for exorbitant prices They made money rapidly, although the government purchased great quantities abroad

Another State Society Journal.—One of the most encouraging signs in the way of organization of the profession is the doing away with the old transactions, which came out once a year, and in the majority of instances were not even opened, and the substitution therefore of the monthly journal Among the latter we welcome the *Journal of the Medical Society of New Jersey*, No 1, of Vol 1, having just been received It has adopted as its title page one similar to that of the *Journal of the Michigan State Medical Society*, which in turn copied the general style of The Journal of the American Medical Association The first issue of the New Jersey Journal is a very creditable one, and promises to be of much value to the profession of the state The editor is Dr Richard C Newton of Montclair There are now thirteen state societies that are journalizing their transactions, namely Arkansas, California, Colorado, Illinois, Kansas, Kentucky, Michigan, Mississippi, Missouri, New Jersey, New York, Pennsylvania, and Wisconsin

CANADA

The Canadian Medical Protective Association held its annual meeting in Vancouver, B C, August 24 Dr Robert W Powell, Ottawa, was re elected president and Dr James A Grant, Jr, Ottawa, was elected secretary treasurer

Toronto General Hospital.—There were 220 patients in the wards on July 31, and 211, not including infants, on August 31 During the month 250 were admitted, 243 discharged and 16 died. During the month 247 accident cases received first aid at the emergency branch of the hospital

The British Columbia Medical Association held a business meeting at Vancouver, August 24, and elected the following officers for the ensuing year President, Dr W D Brydone Jack, Vancouver, vice president, Dr Edward C Hart, Victoria, secretary, Dr H E Langis, Vancouver, and treasurer Dr J S Helmcken, Victoria It was decided to hold the next meeting in Vancouver

Montreal Vital Statistics of 1903—The vital statistician's report for 1903 shows an increase in the birth, marriage and death rates The death rate increased from 22 58 per 1,000 in 1902 to 24 29 The birth rate increased from 35 65 to 36 08 per 1,000, while the marriage rate increased from 9 22 to 10 16 per 1,000 The increase in the two latter rates may be due to the fact that sermons were preached in the Roman Catholic and other churches about two years ago against the falling off in the birth and marriage rates

Vaccination in Montreal—From August 15 until September 3 the vaccination bureau in Montreal was kept open daily to provide for the vaccination of all unvaccinated children who are to attend the schools during the coming terms This was in accordance with the recent by law adopted by the Montreal City Council, which reads as follows "No parent or guardian, no commissioner, trustee or other person shall allow any pupil under his guardianship or control to frequent any school, college, convent, university or any other educational institution in Montreal, unless such pupil shall be provided with a certificate of effective vaccination"

Medical Inspection of City Schools in the Province of Quebec.—The provincial Board of Health of Quebec met recently in Montreal and discussed the high death rate among young children in that city The board approved of the institutions established in Montreal to give advice regarding the care and feeding of babies, and believed that they would be a great assistance in spreading a knowledge of infant hygiene The board will have prepared small booklets for instruction of mothers on the care of new born children Regarding the question of pure milk, the board adopted a resolution asking that municipal health departments make a chemical and bacteriologic examination of milk supplies from time to time, especially in the summer months The board also gave its entire approval to the medical inspection of schools, and will ask the Legislature of Quebec to enact a law which will permit municipal authorities or school commissioners to make a complete inspection, as approved by the congress of the Association of French speaking Physicians A resolution will shortly be adopted to prohibit expectorating on sidewalks

Canadian Medical Association—The thirty seventh annual meeting of the Canadian Medical Association was held at Vancouver, B C, August 23 26, and proved one of the most successful and largest meetings in the history of the organization, there being registered 266 physicians The address in surgery was delivered by Dr Mavo Robson, and was accompanied by a lantern demonstration, that in medicine was delivered by Dr Robert E McKechnie, Vancouver, and that in gynecology by Dr E C Dudley, Chicago, and this was also accompanied by a lantern demonstration The election of officers resulted as follows President, Dr John Stewart, Halifax, N S, vice presidents, Drs Peter MacLaren, Montague Bridge, P F I, Judson B Black, Windsor, N S, Alfred B Atherton Fredericton, N B, Joseph E Dube, Montreal, Harry Meek, London Ont, W S England Winnipeg, Man, Henry C Wilson, Edmonton, N W T and Richard E Walker, New Westminster, B C, local secretaries, Drs Henry D Johnson, Charlottetown, P E I, Guy C Jones, Halifax N S, Thomas D Walker, St John, N B, John D Cameron, Montreal, Alexander Stewart, Palmerston Ont, Samuel W Hewetson, Pincher Creek, N W T Popham, Winnipeg, and

Alexander S Monro, Vancouver, B C, and executive council, Drs George M Campbell, James Ross and C Dickie Murray, all of Halifax, where the 1905 meeting will be held Dr George Elliott, Toronto, was re elected general secretary and Dr H Beaumont Small, Ottawa, treasurer In 1906 it is expected that a conjoint meeting of the Canadian and the British Medical associations will be held in Toronto

FOREIGN

Pensions for Physicians Victims of Epidemics—One of the edicts enacted by the Czar since the birth of his son is one to the effect that the families of physicians are entitled to a pension when the physician succumbed to infection acquired while in the public service fighting an epidemic

Enterprise in Medical Society Work—The physicians and surgeons now stationed or voluntarily serving at Harbin have organized what they call the "Temporary Medical Association in the Far East" At the first meeting, held in August, 96 physicians were present Dr Tolmatschew from Moscow is the president

Russian Physicians at the Front—The Russian Red Cross has appealed for a list of physicians volunteering to serve at the front to take the place of the physicians and medical students worn out or sick from their service with the Red Cross in the field Dr Böttcher has typhoid fever, and Dr Hildebrand had his foot crushed and was the first patient to be treated in the hospital in his charge

Waldeck Rousseau and the German Surgeon.—Considerable surprise has been expressed that Kehr should have been summoned from Germany to operate on Waldeck Rousseau who did not survive the day The facts of the case are that Professors Poirier and Terrier of Paris had performed an operation for biliary obstruction a mon h or so before discovering then indications of inoperable malignant disease in the pancreas The patient's condition was very much improved by the intervention, but the family were warned that the improvement could be only temporary When the threatening symptoms recurred the French surgeons refused further interference, and as a last resource Mayo Robson and Kehr were summoned Kehr performed a laparotomy, and found abla ion of the tumor impossible, although he was able to conclude with drainage of the hepaticus The patient did not regain consciousness, and died in a few hours The French now criticise Kehr for even attempting the operation under the circumstances

Law in Regard to Prescriptions in Brazil.—A new sanitary law for Brazil is under discussion The medical society of S Paulo suggests that every pharmacist shall be supplied with a list of regis ered physicians and that they should be compelled to refuse to dispense prescriptions signed by any one else It is recommended that the original prescription shall not be dispensed again after a year has elapsed from the date of writing No prescription can be dispensed a second time without an order from the physician who wrote it Medicolegal testimony experts should be selected exclusively from the list of registered physicians. B Rodrigues advocated that the government should purchase large supplies of the disinfectants needed in the prophylaxis of epidemics and keep them on hand ready for emergencies When needed they should be sold to consumers at cost At present the prices soar as soon as an epidemic is declared, placing them beyond the reach of the majority The expense to the state would be compensated by the benefits resulting Every cent spent in hygiene is an economy he added. He also added that the public authorities should set the example of abolishing dry sweeping in all the public buildings and avoidance of dust by wiping furniture etc with cloths moistened with antiseptics Example would be worth a thousand precepts

Gloves, Etc., in Field Surgery—Dr Hohlbeck writes from the seat of war that the Russian surgeons are adopting Zoege von Manteuffel's advice to use gloves in field surgery They find them very convenient for applying dressings in severe cases and for operations of all kinds, carrying a supply constantly with them, each pair sterilized in a separate bag He mentions the great benefit derived from Senn's adhesive plaster fastenings for dressings This with the smallness of the wounds made by the bullets, reduces the amount of dressings to the minimum, so that one small package will serve for an astonishing number of wounded The means of transporting the wounded, according to Hohlbeck, are deplorable, the native carts are so clumsy and too short to lie down in The carts supplied by the Red Cross are fine. They are such as are used in Finland and have proved so useful that a large consignment has been ordered The penetrating dust and the millions of flies are the chief enemies of the surgeon The wounds made by the shrapnel balls are the most serious Each bomb contains about 200 balls, and the injuries made by them have all the disadvantages of the old lead bullets The other bombs are much less dangerous They explode with such force that they fly into such small pieces that the damage inflicted is comparatively slight The wounds made by the Japanese bullets are less serious than those of the Lee Metford or Mauser bullets as he observed them in the Boer war They can even pass through the shaft of a bone without solution of continuity Dr Hohlbeck's letters are being published in the *St Petersburger med Wochft*

The Father of Anatomy—Vesalius has been regarded as the father of scientific anatomy, his work "Fabrica," dating from 1543, being styled the first treatise on the subject conceived in a scientific spirit A year or so ago Jackschath arose in Austria and proclaimed that Vesalius had been preceded in this line by Leonardo da Vinci, who, fully fifty years before him, had composed a treatise on anatomy which has since been lost Nothing of this treatise has come down to us except a few students' notes and plates They show, however, that to da Vinci (1452 1519) unmistakably belongs the title of the father of anatomy They also show further, he states, that Vesalius' work is merely a compilation of da Vinci's treatise and that his appropriation of it and publication of it over his own name is the most stupendous example of plagiarism the world has ever known A French edition of what remains of da Vinci's work was published three years ago, and the mistakes made by the author are the same mistakes as are found later in Vesalius' work In a recent number of the *Munchener medicinische Wochenschrift* No 18, G Klein reviews the history of the subject Although he does not think that Jackschrath has quite proved his case in regard to Vesalius' plagiarism, yet late researches have certainly established that to da Vinci and not to Vesalius belongs the title of father of anatomy

Koch and His Critics.—When Koch was presen ed with the *Festschrift* in honor of his sixtieth birthday, and the portrait bust was unveiled, he expressed great appreciation of the homage, especially of i s timeliness He remarked "The good old days of bacteriology are past, when a few investigators had the field to themselves and could work in peace along their various lines Now their name is legion, and every one of them is striving to win some small modicum of success No one has a free field to himself any longer, and even with the most cautious limitation of one's field of work one finds that he is encroaching on another's domain, or stepping on still another's toes, or jostling some one in some way Before the scientist knows it, he has made a host of enemies on all sides This is naturally very unpleasant and robs one of all peace and joy in one's work" Koch continued with the statement that he had been particularly unfortunate in this respect, whatever he writes or says raises a storm of passionate contradiction It generally comes from those who understand little or no hing of the matter in hand and are the least qualified to pass judgment on it He has frequently been tempted to abandon the whole thing and have nothing more to do with science This homage offered to him on his sixtieth birthday showing such a large and loyal band of co workers, is an inspiration to keep on working, and he terminated with the promise to continue to devote his energies in the future as in the past to work with and for these loyal friends, to promote the cause of science by every means in his power Von Behring was at one time a pupil of Koch, and his absence from the celebration excited some comment

Wounds from the Japanese Firearms.—The Japanese bullets used at the battle of Vafangou were an inch and a quarter long and a quarter of an inch in diameter A detailed report from one of the Russian surgeons of his work after the battle states (in the *Russki Vratch*, iii, No 30 July 24 1904) that these bullets passed through bone and tissue without shattering them, merely making a tunnel the size of the bullet His hospital was located at Tielen more than 200 miles from the battlefield, and the 150 wounded men arrived by train, all but a few having walked from the scene of action to the nearest railroad station, a distance of 20 to 30 versts (nearly 14 to 20 miles) All arrived the second day after the battle in satisfactory condition, none thinking that his wounds were serious al hough in some of them the bullets had traversed vital regions Only 5 required operative intervention in 4 the bullet was extracted under cocain, one was a shrapnel ball In another case crushed fingers were amputated Treatment was limited to thoroughly cleansing the wound and putting it in the best condition for natural repair Four cases are described in which the bullet passed through the thorax In one the bullet entered below the right seventh rib and emerged in the ninth interspace The man was standing about 500 paces from his assailant He did not fall, but hastened on foot to the railroad station, more than 13 miles away There was no hemorrhage, and merely slight difficulty in breathing Slight fever was observed for three days after arrival, but by the eleventh day all the symptoms had vanished except that the breathing in the lower lobe of the right lung was not so strong as in the other lung The patient felt quite well Another was hit at about 800 paces, the bullet emerging in the tenth interspace He experienced merely a slight difficulty in breathing and repaired to the station on foot, finding that an attempt to ride in a wagon made him feel worse The lung action was apparently normal, there was no fever, and the patient felt perfectly well by the end of the second week There was some suppuration of wounds of the abdomen or mouth, but healing proceeded rapidly The surgeon in question, J B Zeldovitch, comments on the courageous bearing and good humor of the wounded, their expressions of admiration for the valor of the foe and the lack of revengeful feelings

Correspondence.

Physicians in the Public Life of France

PROFESSOR POZZI—COMBES A PHYSICIAN—COMPOSITION OF THE FRENCH SENATE—THE CHAMBER OF DEPUTIES—PHYSICIANS IN MINOR CIVIL OFFICES—SCIENTIFIC RECORDS, PROFESSIONAL AND PERSONAL STANDING OF PHYSICIANS IN PUBLIC LIFE—SOME NEGLECTED BUT PRESSING DUTIES OF AMERICAN PHYSICIANS

PARIS, Aug 27, 1904

To the Members of the Medical Profession —The active participation of the medical profession in public affairs in France is in striking contrast with the aloofness of American physicians from executive and legislative offices This was brought to my attention by Professor Pozzi, with whom it was my good fortune to cross the ocean on his return from the meeting of the American Surgical Association at St Louis He himself is an example of the highest type of the medical man, using the term in its broad generic sense A successful practitioner, the author of an accepted text book of gynecology which has been translated into all the European languages, a litterateur and scientist in a broader sense, having been the translator of Darwin into French, a member of the Academy of Medicine, a popular professor in the Ecole de Médicine, an officer of the Legion of Honor, an active participant in the Franco Prussian war, he has held several minor civil offices and, lastly, has had one term as a senator of France Yet he is only in the prime of manhood! His example, it is hoped, will be as generally emulated in America as it is imitated, consciously or otherwise, in France When I told him that there were but two physicians in the United States Senate and none in our House of Representatives of the United States he was greatly surprised

Why!" he exclaimed, "in France medical men are not infrequently the controlling factors in both the Senate and Chamber of Deputies! Out of the more than 600 members in both branches it is not unusual to have from 100 to 125 representatives of our profession"

"What about their politics?" I asked

"They are chiefly Republicans, most of them belonging to the 'Republican Radical' branch of the party, only a few are classified as 'Republicans' and 'Moderate Republicans,' while it is still more rare for a physician to belong to the 'Right' or Clerical party"

"Are the medical representatives co operative on professional and scientific questions without reference to party lines?'

Yes Always and effectively"

'Do medical men frequently hold local political office?'

Yes they are frequently members of the general counsels of the various departments and mayors of cities In this connection I might mention Lyons, Bordeaux, Nancy, Rheims and other important cities"

Dr Pozzi kindly put me in the way of ascertaining the facts relating to the senate, of which he was once a member The body consists of 300 members, of whom 40 are medical men! Think what might be accomplished in the way of needed and wholesome legislation in the United States if our medical profession were only represented in similar proportion in the two branches of Congress!

I am convinced that the medical profession in the United States is too largely actuated by the idea that participation in political affairs will be accepted as an evidence of corresponding inefficiency in professional attainments The people, too, seem to hold the view that if a man is of any account as a physician he can be of no account as a politician and *vice versa* These ideas or prejudices, provincial as they are, have without doubt exercised a repressive influence on physicians in general in the exercise of their citizenship It is of some interest, therefore, to study the facts in a country in which examples are sufficiently numerous to be instructive No country can be more to the point than France, and no body in France can be more illustrative than the Senate, concerning the members of whom I have been fortunate enough to secure the data

Take for example Combes whose actions and utterances are commanding more attention than those of President Loubet himself It is the same Combes who, as the successful instigator of the crusade of the republic against the religious orders which he has expelled from France, has accomplished, in a peaceful way, results as great as were the reforms embraced in the Revolution of 1793 and again in that of 1849 His moral courage is as heroic as any that was ever more dramatically displayed on the field of battle by a general of France This man has served as a member of the general council of his department that of Charente Inférieure, was once mayor of Pons, was elected senator in 1885, and again in 1894, was vice president of the Senate, served as a minister of public instruction in 1895 96, was re elected senator last year, and is now minister of the interior and president of the council of state This man is not only a philosopher and historiographer of distinction and the author of a psychologic work, but he is a doctor of medicine, having begun his life as an active member of that profession

The special question at issue is Do physicians who figure prominently in the politics of France amount to anything in a professional way? I have already cited Pozzi and Combes Let us look up some who are not so distinctly world men—men who are known only, or at least chiefly, in France, and information concerning whom will, therefore, be more in the nature of news Take, for instance, Gauthier, senator from Aude He is laureate of the Faculty of Medicine, received distinctions for his service in the cholera epidemic of 1885, made important investigations in the chemistry of iron and, so I am advised, enjoys as a physician the unlimited confidence of the people of Sijean, where he lives Peyrot, senator from Dordogne, is the author of numerous contributions on surgery and is a leading surgeon in that part of France Saillard, senator from Doubs is the professor of surgery at Besançon, while his colleague Borne, from the same department, is known throughout France by his writings on pleurisy and the neuralgias Campaian, from the Haute Garonne, is an accepted authority on the thermal waters of France Perreal, from Hérault, received a medal from the government for his work in cholera epidemics and for his contributions on the subject Parisot, from Vosges, received formal distinctions for his labors in the propagation of vaccine, and many others

The personal standing of these men in their respective communities is still another question of interest and one which can be answered only inferentially, at least, by the record Thus, for example, one would infer that a man like Perreal, senator from Hérault, is a man of local force and esteem when it is recalled that he was born in 1825, that he has served as a member of his general council has been mayor of his city for ten years, has been identified with the medical school at

Grenoble was a victim of the historic second of December joined the insurrection against the empire, served as an officer of public instruction, and finally, in 1897, when 72 years of age, was elected to the Senate, of which he is still an active member Campuan, from the Haute-Garonne, is another He was born in 1832, like his colleague, opposed the empire, was the efficient inspector of thermal waters, one of the largest interests in France, busied himself with his farms, of several of which he is the successful manager and proprietor, after twenty three years of strictly professional work he in 1879 went to the Senate, where he has since seen constant service as a Republican These are certainly inferential evidences of high local esteem for a man with such a record as this

It was my good fortune the other day to visit the beautiful little city of Annecy, the capital of the department of the Haute Savoie, which is represented in the Senate by Dr Francoz He is a native Savoyard, who began his professional career in his beloved mountain country and who chose to serve his people still further by serving as a general councillor, having acted as president of that important body, then is acting mayor of Annecy He became an officer of the Academy —a distinction which carries the laurel with it in France and went to the front against the Germans He was not at home when I called, a circumstance which gave me additional excuse for making inquiries concerning him

"Dr Francoz has been senator for some time?" I inquired of an advocate whom I had the good fortune to meet.

Ah yes for about ten years"

"He has been an efficient senator?"

'That is shown by the fact that he has been once re elected and that he has served as secretary of the senate"

'He must be highly esteemed personally and professionally by his neighbors" I ventured

'Ah yes, monsieur, he is the first citizen of Haute Savoie—the premier physician, too Even his political enemies admire him There are many who deplore his absence in Paris but it can t be helped he is needed in the Senate!"

The physicians in public life in France are esteemed members of their respective communities

I have not had time to look up the facts relative to the Chamber of Deputies, but I am advised that they are not essentially different from those which I have presented in regard to the Senate. Be this as it may however we must recognize that the medical profession of France is setting an excellent example to that of the United States relative to the recognition and discharge of the broad duties of citizenship I am sure, however that with the facts brought home to them the physicians of America will be more in evidence than heretofore in state legislatures and in Congress We have a distinct duty to perform in that regard There are already a number of candidacies for Congress by medical men in different parts of the country It is highly important where party interests are not distinctly paramount, to see that such candidacies are made successful Over and above this, however it is important that the medical profession right now both through its organized local bodies and by direct personal interrogation should demand of all candidates for elective office an explicit statement of their views touching specific questions of interest to the medical profession and to the public health Wherever practicable a committee should be appointed to report on the previous records of candidates touching such questions for records made are safer criteria than promises given on the eve of election Careful consideration should be given to such reports and medical men should govern themselves accordingly remembering always that they are 150 000 in round numbers and that they can exert a powerful influence if they will but do so, by quietly and confidentially advising their friends and patrons on political questions or, if they prefer by going openly on the hustings CHARLES A L REED

Light for Eye Work Etc.

CHICAGO Sept 8 1904

To the Editor —An ideal light for eye ear nose and throat work is made by dipping a suitably sized segment of the frosted portion (sand blast formation) of a 24 candle power spiral electric lamp in hydrofluoric acid After dipping it in the acid for a few seconds, wash it off in water, dry and test its translucency Each application of the acid eats the rough points of glass, leaving it thinner, smoother and more nearly transparent Continue this until light of desired intensity is obtained, yet stopping short of the point where the reflection of the coil can be produced by a forehead mirror held at its focal distance from a smooth surface as well as from the lamp A uniform and intense white light is obtained

I have suggested to a bulb maker that where an asbestos chimney is needed a plain bulb small enough to be placed in the chimney could be used and fitted with the same shaped spiral coil of equal candle power Then a glass disc treated as above may be placed in the fenestrum of the chimney

AIDING AND ABETTING QUACK INSTITUTIONS

A censor of a county society writes us in regard to a case in which a member of his society has been proven guilty of consulting with and aiding professionally those who are conducting an advertising so-called medical institute ' those connected with it being of unsavory reputation and not recognized professionally in any way After enlarging on the case our correspondent asks

In view of the large number of well known advertising medical institutions in many of our cities and the not uncommon condition of otherwise reputable physicians having professional and business relations with them it should be understood whether such physicians can aid and associate with such institutions and at the same time be recognized and be retained as members of a county society

ANSWER.—In some parts of the country it is not unusual that some otherwise reputable physician acts directly or more often indirectly as consultant to one of the too many so-called medical institutes etc that are conducted by quacks The physicians who do this certainly do far greater and more real damage to our profession than those who consult habitually with homeopaths eclectics etc who are personally honorable The pressure of necessity in a crowded profession renders many of us keen for financial returns, and the substantial inducement of the quack under secret arrangement at times proves to be a too great temptation Those who yield should not expect to retain professional position and fellowship for this conduct is decidedly ' unprofessional in that it gives comfort and support to the worst of quacks The damage to the profession is great. for the patient referred by the institute to a specialist is bound to conclude that the profession countenances quietly the quack whom it openly condemns and there is nothing to keep the patient from spreading the knowledge thus gained The harm that results to professional prestige is inestimably grave not considering the patient s side of the question Under the new organization, each county medical society is fully endowed with authority to stamp out such practice if unfortunately any of its members succumb to the temptation No explicit reference to this particular dereliction in professional duty is made in the Principles of Ethics but the spirit of the medical profession is decidedly against the recognition of such practice as regular It is unnecessary to enact new legislation to stamp out this evil in the few places where it exists Every county society will deem it unprofessional conduct and can be depended on to discipline the member who is found guilty

THE COUNTY SOCIETY SHOULD DECIDE ETHICAL QUESTIONS

A censor of a County Medical Society in Oklahoma asks Can a member of a county medical society—branch of the American Medical Association—consult with and otherwise professionally recognize, a non member one who has often supplanted physicians where he has been called in consultation?

ANSWER.—Such a question to-day is made almost purely local by the reorganization of medical societies that has been progressing since 1901 and that is now nearly completed The county medical society in the new scheme of organization has full authority to determine its own course in questions ethical Already this has led to considerable differences between the customs of different county societies This seeming irregularity of custom on the whole is a result of the adoption of a mode of real organization and of a non penal Principles of Ethics Local professional customs necessarily differ e g as between Chicago and a sparsely settled county in Maine or as between San Francisco and a back county in Arkan sus The chief good however, is in the making of the county society the autonomous unit of medical organization with full power to decide its own ethical course and to penalize members whose conduct departs therefrom

Therefore, we would advise our correspondent that his own society should determine what course its members should pursue in this particular circumstance No one is so familiar with the conditions and with the needs of the case as those who are practicing on the spot Of course, their decision should be guided by the spirit of the Principles of Ethics If the erring physician could be brought to see and to abandon the error of his way and to come within the fold of medical organization a double benefit will ensue, a new recruit will be enrolled and a disturber of the peace suppressed This is by far the best method If for any reason it can not be followed, or if it meets with failure, there is no one in such advantageous position to decide on the best further course than the members of the county society If it deems it wise the society can adopt a rule threatening suspension from membership to those who consult with the offender We would not advise such a course and mention it only to illustrate the functions and authority of the county medical society Some other less drastic course should be found effective

RIGHT TO PRACTICE IN IRELAND

MINNEAPOLIS MINN, Sept 9 1904

To the Editor —1 What are the requirements of an American physician who is a graduate of a regular recognized American college to practice medicine in Ireland?

2 Can one enter the regular course of the Dublin Trinity College of Medicine or the other schools, on presentation of credits received from an American college without examination and then graduate? If so, what other school s credentials are recognized?

J W M

ANSWER —1 The right to practice medicine in Ireland is obtained only by those who have passed the examinations of one of the various licensing boards or who have obtained the M D degree from a recognized university of Great Britain or Ireland There are several licenses recognized among which may be mentioned the Royal College of Physicians of London, the Royal College of Surgeons of England Society of Apothecaries of London Royal College of Physicians of Edinburgh Royal College of Surgeons of Edinburgh Royal College of Physicians of Ireland Royal College of Surgeons of Ireland and Apothecaries Hall of Ireland These vary slightly in their requirements Some of these licensing bodies recognize certain degrees in this country The University of Dublin grants the degree of M B and M D and also B Ch and M Ch (Bachelor and Master in Surgery respectively) A candidate for any one of these degrees must be a graduate in arts 2 No unless one has also a recognized degree in arts

A MEDICOLEGAL QUESTION

———, NEB, Sept 3, 1904

To the Editor —Three years ago I was called to see a married woman suffering from an abortion The husband refused to pay and I brought action During the trial the attorney asked me who called me to the case I could not remember I won in the lower court, but it now goes to the higher court Will I have to know definitely who called me to see the woman, and if I can not tell, will I lose the case?

F P D

ANSWER —It would hardly seem that the case against the husband could be lost on the mere failure to remember who called you to attend his wife unless there were exceptional circumstances to render that a vital point The Supreme Court of Nebraska has held in the case of Spaun vs Mercer S Neb 357 that for medical services bestowed on the husband himself, or on his wife and children by whomsoever the attendance of the physician may have been requested, the husband and not the wife is ordinarily liable Especially is this so where the credit was in the first instance given to the husband and where there was no special agreement on the part of the wife to bind her separate estate

SWALLOWED A LARGE STAPLE

DR WADE SPERRY, Hamburg Iowa, writes Referring to Dr Stratton s case on page 558 of THE JOURNAL August 20 I had a similar case A boy 1½ years old swallowed a new fence staple an hour before he was brought to my office As he showed no bad symptoms I had my doubts about it However, I prescribed as many ripe bananas as he could eat He ate three afterward he was given a tablespoonful of castor oil The next morning, 12 hours later, he passed the staple It was a new one, with very sharp points No bad symptoms afterward

PROFESSIONAL CARDS IN LOCAL NEWSPAPERS

——— MONT, Sept 1 1904

To the Editor —Does the best sentiment of the profession permit a physician to follow the custom of his town in regard to a card in the newspaper?

I am a newcomer in a small country place and find the card (with name, the legend 'Physician and Surgeon' and address of office) of each of my fellow physicians in the weekly country paper

I P R

ANSWER —Yes Under just the circumstances mentioned, professional custom has sanctioned the publication in local papers of a card containing no more information than that specified by our correspondent

Marriages.

WALTER STIX, M.D, to Miss Edith Fechheimer, both of Cincinnati

OSCAR EDWARD FISCHER, M D, to Miss Irma Hadzsits, both of Detroit, September 1

F BRUCE COCHRAN, M D, Milan, Mo, to Miss Mary Simmons, at Lake, Ind, August 31

INMAN W COOPER, M D, to Miss Hortense Crutcher, both of Newton, Miss, September 7

AUGUSTUS A ESHNER, M D, to Miss Julia Friedberger, both of Philadelphia, September 7

CLAUDE F SH ONTS, M D, Hospital, Ill, to Miss Jeannette Foster, at Chicago, September 14

BENJAMIN H SHERMAN, M D, Dexter, Iowa, to Miss Jessie Loar of Monroe, Iowa, September 1

GRANT A REBER, M.D, Fentress, I T, to Miss Estelle Blake of Salina, Kan, September 14

H WINNETT ORR, M D, Lincoln, Neb, to Miss Grace Douglas of Grinnell, Iowa, September 7

ALBERTUS A MOORE, JR, M D, New York City, to Miss Agnes Remsen Vrendenburg of Freehold, N J

JOHN G YOUNG, M D, to Miss Mae Wells, both of Hickory Grove, Ill, at Keokuk, Iowa, August 31

RUSSELL A HIBBS, M D, New York City, to Miss Madeline Cutting of Pittsfield, Mass, September 1

WORCESTER A BRYAN, M D, Nashville, Tenn, to Miss Emma Berry, at Hazelpath, Tenn, September 14

STEPHEN TYLER PARSONS, M D, Aplington, Iowa, to Miss Rachel Hutchison of Chicago, September 6

WILLIAM GRAY ALLEN, M.D, Chicago, to Miss Amelia Harrison Arundale, at Bradford, Ill, September 7

WILLIAM BROOKS LA FORCE, M D, Ottumwa, Iowa, to Miss Anna Carolina Bosquet of Pella, Iowa, August 31

OLIVER BIERNE PATTON, M D, Huntsville, Ala, to Miss Carlisle Dorothy Walker of Richmond, Ky, August 30

THEODORE DROSDOWITZ, M D, Chicago, to Miss Belle D Hurwitz of New York City, at St Louis, Mo, September 5

HARRY E CLEMSON, M.D, Port Deposit, Md, to Miss May Oakford of Philadelphia, at Washington, D C, August 25

ROBERT FRANCIS MORRISON, M D, Holyoke, Mass, to Miss Elizabeth Blanche Smith of Chicopee, Mass September 7

FLETCHER HODGES, M D, Indianapolis, Ind, to Miss Rebecca Trull Andrews of Manchester by the Sea, Mass, September 1

WILLIAM MUEHLBERG, M D, to Miss Edna Zinke, daughter of Dr E Gustave Zinke, both of Cincinnati, at Idaho Springs, Colo, September 7

WILLIAM CARY MABRY, M.D, acting assistant surgeon, U S Army, Fort Sheridan, Ill, to Miss Bessie Mayne of Salt Lake City, Utah, September 7

Deaths.

Augustus B Castle, M D Transylvania University Medical Department, Lexington, Ky, 1841, surgeon of the First Kentucky Volunteers in the Mexican War, thereafter a practitioner near Lexington, Ky, and Kansas City, Mo, chief surgeon of the military hospitals at Macon and Fayette, Mo, during the Civil War, who was obliged to retire from practice soon after the war on account of ill health, and lived on his plantation until 1898, when he moved to California, died at Los Angeles, July 29, aged 85

Albert G Miner, M D Jefferson Medical College, Philadelphia, 1873, a member of the American Medical Association, surgeon of the One Hundred and Seventy first Ohio Volunteer Infantry in the Civil War, and some time city councilman of Niles, Ohio, while driving across a grade crossing near his home in Warren, Ohio, August 31, was struck by an express train and instantly killed, aged 67 His wife, who was with him in the carriage, was also killed

George Newton Lantz, M D University of Louisville, 1890, president of the Linn County Medical Association, member of Grand River Medical Society, North Missouri Medical Society, and of the Medical Association of the State of Missouri, died at his home in Brookfield, Mo, September 2, from Bright's disease

James M Bowcock, M.D Jefferson Medical College, Philadelphia, 1856, died recently at his home in Clarksburg, W Va, after an illness of eighteen months, aged 75 The Harrison County Medical Society, at a special meeting, August 31, passed resolutions of regret

John L J Gormly, M.D Long Island College Hospital, Brooklyn, 1897, a member of the King's County Medical Society, and visiting surgeon to St Mary's Hospital, died at his home in Brooklyn, September 7

John H Shaper, M D University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1891, died at his home in Herkimer, N Y, September 3, from dysentery, after an illness of one week, aged 30

Orlando C Robinson, M.D Department of Medicine of the University of Pennsylvania, Philadelphia, 1881, died at his home in Bethayres, Pa, August 4, from pulmonary tuberculosis, aged 44

Philip G Gary, M D University College of Medicine, Richmond, Va, 1900, of Wakeman, King William County, Va, died at the Newport News Hospital, from typhoid fever, September 7

William Hammett Martin, M D College of Physicians and Surgeons in the City of New York, died at his home in New York City *from cancer of the stomach*, September 3, aged 40

Charles Meyer, M.D Berlin University, Germany, 1848, a veteran of the Schleswig Holstein campaign, died at his home in Macungle, Pa, September 2, from apoplexy, aged 77

I. T Tichenor, M.D Kentucky School of Medicine, Louisville, 1854, died at his home in Stringtown, Nelson County, Ky, August 29, from gangrene, after a long illness, aged 72

Benjamin Parker Barstow, M D Massachusetts, 1892, of Kingston, Mass, died at the Channing Hospital, Providence, R I, from septicemia, August 25, aged 44

Leonard Henley, M.D Department of Medicine of the University of Pennsylvania, Philadelphia 1847, died at his home in Williamsburg, Va, August 5, aged 83

Byron Lemly, M D Medical College of Virginia, Richmond, 1865, died at his home in Jackson, Miss, August 29, from apoplexy, after an illness of several weeks

Joseph F Wheeler, M D St Louis Medical College, 1875, died at his home in Marshall, Mo, September 6, from Bright's disease, after a short illness, aged 60

William W D Parsons, M.D College of Physicians and Surgeons in the city of New York, 1852, died at his home in Auriesville, N Y, July 19, aged 72

John B Taylor, M.D University of Maryland School of Medicine, Baltimore, 1855, died at his home in Ivy Depot, Albemarle County, Va., September 2

John Robert Hamilton, M.D College of Physicians and Surgeons of Ontario, Toronto, 1872, died at his home in Clinton, Ont, July 12, aged 56

John Thomas Brosnan, M D Bellevue Hospital Medical College, New York City, 1893, died at his home in Brooklyn, September 9, aged 30

George S Limerick, M.D Bellevue Hospital Medical College, New York City, 1891, died at his home in Vicksburg, Miss, July 8, aged 40

Philip Eugene Craig, M D Baltimore Medical College, 1897, died at his home in Baltimore, September 10, from typhoid fever, aged 35

Harry M Adams, M.D St Louis College of Physicians and Surgeons, 1864, died in June from peritonitis at his home in Worden, Kan

Edward B Holt, M.D Harvard University Medical School, Boston, 1868, died at his home in Lowell, Mass, July 19 aged 49

William H. McRee, M D Medical College of Georgia, Augusta, 1859, died at his home in Stephens, Ga, August 30, aged 76

Henry E Parker, M D Illinois, 1878, died at his home in Lorain, Ohio, August 30, after an illness of two years, aged 52

J E Waters, M.D Illinois, 1877, died suddenly at his home in Athensville, Ill, July 30, aged 76

Edwin W Knepper, M D Indiana, 1897, died at his home in Ligonier, Ind, April 29, aged 70

David H Armstrong, M D, died at his home in Austin, Texas, September 3, aged 74

Adin Hubbard Newton, M D, died at his home in Everett, Mass, July 7, aged 87

H C Banner, M D, died at his home in Erwin, Tenn, August 31, aged 55

Seth C Archer, M.D Ohio, 1865, died recently at his home in Milan, Ohio

Deaths Abroad

Franz Riegel, M.D, the well known professor of clinical medicine at Giessen since 1879, died, August 26, aged 61 His name is familiar from his works on the heart action, the pulse, especially the venous pulse, heart "bigeminie," lead poisoning, acute nephritis, etc. His manual on gastric affections is now in its second edition The dominant idea with him in the consideration of pathologic conditions was always the disturbance *in the physiologic function Without detracting from the value* of pathologic anatomy, he regarded the pathologic function as indispensable to a knowledge of the affection in question His favorite fields of work were those in which the disturbed function was the chief element in the symptom complex His work was further distinguished by his indefatigable study of the subject in hand from every possible point of view The twenty fifth anniversary of his professorship was celebrated last May, when the *Münchener med Wochft* published a fine portrait of him

A. S Landerer, M D, professor of surgery and director of the Karl Olga Hospital at Stuttgart, died in Switzerland, August 21, aged 50 He has published many works on surgical and other subjects, but his name is best known, perhaps by his advocacy of cinnamic acid in the treatment of tuberculosis Since he introduced this method of therapeutics twenty years ago, he has unceasingly proclaimed its value basing his judgment on theoretic premises and clinical experience, but his views have not been generally accepted Two years ago he was appointed to be director of a large public hospital approaching completion in a Berlin suburb

Association News.

REPORT OF THE SCIENTIFIC EXHIBIT

Of the American Medical Association, at Atlantic City, June 7-10, 1904

FRANK B WYNN, A M, M D, DIRECTOR
INDIANAPOLIS

Four years ago in Atlantic City the first scientific exhibit *of the Association* was auspiciously inaugurated It was perhaps, the most distinctive feature of that memorable meeting The practical benefits of the Scientific Exhibit have since been abundantly demonstrated In its evolution, experience soon proved the large heterogeneous collection expensive and difficult to demonstrate Reduction in size of the exhibit followed naturally with grouping of specimens to illuminate certain phases of pathology The next step was to correlate the work of the exhibit with that of the sections Topics chosen for illustration were those of live interest to the profession and prominently considered in the sections

Those having deeply at heart the best development of this feature of the association work, have striven long and earnestly for one all important end, viz, systematic demonstration of the exhibit by competent persons at stated hours indicated on the official program *Realization of this object was attained* at the past session On Wednesday and Thursday afternoons demonstrations of a practical nature were made in the exhibit hall by men of distinction The participants were William H Welch, W T Councilman, Harvey W Wiley, W M Late Coplin H A Christian, Edward H Nichols, C Y White, Winfield S Hall W B Cannon, W G Spiller, D J McCarthy, J E Greiwe W T Longcope I W Blackburn, F C Busch and others

The large attendance on these demonstrations and the close attention shown gave ample proof of their success In the future they should be arranged with reference to topics in the section programs A series of demonstrations might be arranged, for example which would be of particular interest to the internists, another series to the gynecologist, etc The respective sections might set aside certain hours of their published program for witnessing the demonstrations of interest in the exhibit hall

In point of artistic excellence the last exhibit easily surpassed any previously made It will be noted also that research work of recognized scientific and practical value was shown This is highly creditable and conducive to the scientific prestige of the organization Research exhibits are highly desirable, but should not constitute a dominant feature The prime object of the exhibit is educational It should appeal of course, to the investigator But it should never be forgotten that the American Medical Association is a democratic organization The exhibit should seek, therefore, also the instruction of the rank and file of the profession, in recent scientific knowledge of direct bearing on practical medicine A *specimen of hepatized lung or a contracted kidney may seem* very common and uninteresting to an expert pathologist, but to the observant practitioner they offer an instructive object lesson And surely a thorough knowledge of gross pathology offers the safest foundation for expert diagnosis And thus since the inauguration of the exhibit, practical dissemination of pathologic knowledge has been going on

A most beneficent influence of the Scientific Exhibit has been the stimulation of the collection of gross museum specimens in reputable medical colleges and their artistic preparation for teaching purposes Those who visited the first exhibit four years ago and the last one must have been impressed by the marked artistic improvement in the specimens shown The Scientific Exhibit therefore, has made no small contribution to medical education by arousing among colleges a wholesome rivalry in the exhibits shown

A beneficent influence of the exhibit has been to emphasize gross as distinguished from microscopic pathology The improvements of the microscope and the triumphs of bacteriology have led many teachers to neglect those things which may be studied with the unaided eye Few of the medical institutions of the country are thoroughly equipped with museum collections for teaching purposes A considerable number of creditable museum collections have grown up in the last four years directly as the result of the work of this Association

The membership of this organization includes an army of medical workers—generals, captains, experts and, most important of all, the common soldiers who bear the brunt of the battle against disease To all the Scientific Exhibit is a most helpful agency, capable of still greater usefulness Closer correlation of the work of the sections with that of the exhibit, complete illumination of a few live topics each year competent demonstrations by men of ability, fuller realization of the intimate relationship of the exhibit to the sections these things will make for the still greater efficiency of the exhibit

The many scientific workers who have labored so earnestly for the success of this exhibit have as their reward the satisfied consciousness of a duty well *performed and the enthusiastic* approbation of the profession The details of the respective exhibits are given below

BOSTON UNIVERSITY SCHOOL OF MEDICINE

W H WATTERS O R CHADWELL AND HENRY WATTERS

1 54 *Series of Appendices* mounted in special tubes illustrative of the catarrhal ulcerative obliterative and other types of appendical disease

55 100 These were miscellaneous specimens and included A lung series kidney series, lymph gland series series of carcinoma of breast showing erosion retraction of the nipple and metastasis

These were all Kaiserling preparations mounted in glycerin jelly Most of the mounts were in Petri dishes on ground glass plates, which gave an excellent background for the specimens Great credit is due this institution not only *for this* beautiful exhibit, but for a similar one made at the Saratoga session Dr Henry Watters was in charge of the collection

CINCINNATI HOSPITAL MUSEUM

J E GREIWE

HEART SERIES

101 *Acute Pericarditis*

102 *Tuberculosis of Pericardium* involving the entire cardiac surface and associated with marked hypertrophy of left ventricle

103. *Tuberculosis of Pericardium,* with extreme dilatation of the sac which contained five pints of blood stained fluid at *necropsy*

104 109 *Adherent Pericardium* —Of interest in these specimens was the constant association of hypertrophy and the frequency of aortic lesions

110 *Intramural Blood Clot* the size of a walnut situated in the apex and surrounded by a dense wall of connective tissue

111 *Secondary Sarcoma of Myocardium* —Primary trouble of the liver

112 *Concentric Hypertrophy* with diminution in size of left ventricle No valve lesions

113 *Acute Suppurative Myocarditis* secondary to septic pneumonia Thrombus of coronary and miliary abscesses throughout myocardium

114 *Degenerative Changes of Aortic and Mitral Leaflets* —Marked atheroma of the coronaries extreme bradycardia—pulse 28

115 *Unusual Acute Obstruction of Coronary* —The specimen was obtained from a lad of 12 who died suddenly The autopsy revealed an acute vegetating endocarditis The edge of one aortic valve became torn loose remaining attached at one end while on the free extremity were three small globular vegetations These small masses were found obstructing the coronary vessel

116-118 *Lesions of Aortic Valves and Aortic Ring*

119 *Vegetations of the Aortic Valves* with perforation of the septum ventriculorum

120 *Extreme Calcareous Infiltration of Aortic Valves*

121 *Aortic Stenosis* —*Cor Bovinum*

122 *Aneurism of Aorta. No Ventricular Hypertrophy*

123 *Aortic Regurgitation* —Hypertrophy and dilatation of left ventricle and secondary insufficiency of mitral valves

124 *Mitral Stenosis* —papillary muscles converted into thick fibrous bands

125 *Vegetations on Mitral Leaflets*

126 *Marked Stenosis of Mitral Orifice*

127 *Endocarditis Verrucosa* with infarcts in spleen kidney and brain

128. *Globular Vegetations* located below the aortic valves

129 *Combined Lesions of Aortic Mitral and Tricuspid Valves*

130 *Mitral Disease with Extreme Dilatation of Right Heart* —Great irregularity of pulse

131 133 *Mitral Regurgitation* —Great hypertrophy and dilatation of left heart and secondary insufficiency of tricuspid orifice.

This excellent heart series was demonstrated by Dr Greiwe and, taken with the beautiful kidney group exhibited at New Orleans a year ago, speaks well for the character of pathologic work being done at the Cincinnati Hospital This makes the fourth successive year in which this institution has been a contributor to the Scientific Exhibit, and has, therefore, played no small part in building up this feature of the Association work

HARVARD MEDICAL SCHOOL

(A) DEPARTMENT OF PATHOLOGY W T COUNCILMAN HENRY A CHRISTIAN AND EDWARD H NICHOLS

This very complete exhibit consisted chiefly of bromid enlargements of photomicrographs and paintings of gross lesions They showed an unusual degree of beauty and clearness of microscopic detail They were neatly framed and in the university are used for wall decoration as well as teaching

134-147 *Parasite of Smallpox*
148-155 *Lesions of Smallpox*
156-158 *Vaccinia.*
159 161 *Parasite of Scarlet Fever*
162-163 *Parasite of Aleppo Boil*
164-178. *Malarial Parasites*
179 190 *Cirrhosis of Liver*
191 206. *Lesions of Typhoid Fever*
207 224 *Lesions of Lymphatic System*
225-242 *Lesions of Diphtheria Membrane Lung and Kidney*
243-250 *Neuroglia Tissue from Subcoccygeal Glioma*
251 255 *Neuroglia Tissue in Dermoid Cysts*
256-258 *Bacteria.*
259 265 *Lesions Due to Bacteria.*
266-268. *Tubercle Bacilli (human) Grown on Different Media*
269-271 *Tubercle Bacilli (bovine) Grown on Different Media.*
272 283. *Lesions of Tuberculosis*
284 298. *Lesions of Chronic Non Tubercular Arthritis*
299 315 *Lesions of Chronic Non Tubercular Arthritis Paintings*

In addition to the above photomicrographic exhibit, lantern demonstrations were made covering much the same field by Drs Councilman, Christian and Nichols The large attendance on the occasion attested the great interest taken

(B) DEPARTMENT OF PHYSIOLOGY

W T PORTER AND W B CANNON

This exhibit consisted of apparatus for the advancement of laboratory teaching in physiology and allied sciences It was designed by Dr Porter and presented by Dr Cannon

316-320 Kymograph Inductorium and a Number of Other Pieces of Apparatus

These instruments, which have found extended use both here and abroad, were designed for the following ends

The making of physiologic apparatus distinguished by simplicity of design, sound workmanship and low cost is of high importance in the development of physiology The ordinary student of physiology is essentially a book man, while the professional physiologist is essentially a laboratory man Student and professor should go the same road, along which few steps can be taken without apparatus of precision Physiologic apparatus has heretofore been made on the "model" plan, each for itself, without regard to the number of "operations" required, and with little or no thought as to the subsequent maintenance of the apparatus in good condition A large laboratory class requires a great supply of apparatus One hundred and fifty men working in the physiologic laboratory every day during four months require more than 25,000 articles It is clear that the cost of such an equipment, made on the old lines, would be too great for any school The sound training of large classes in physiology depends absolutely on the invention of apparatus designed with reference, 1, to its "manufacture", 2, to its storage and issue, 3, to its maintenance in good condition

By "manufacture" is meant technically the making of a large number of "parts" for the same apparatus consecutively, by preference on special lathes and with special tools The number of steps or "operations" should be the fewest possible, as each operation must be repeated many times The labor of "setting" a turret lathe, which will make eight operations with eight different tools on the same piece of metal, is as great for one piece as for a thousand Astonishing economics may also be secured by the use of special automatic devices

Effective storage and issue also demand that the apparatus be compact and that important parts be protected so that they may not be injured when the apparatus is handled rapidly by persons of small experience Economic maintenance requires construction with special reference to durability and cleanliness

With all this the apparatus must be admirably exact, serving the student for the repetition of classical experiments, and satisfying the investigator for all the ordinary needs of research

The supply of apparatus of this type bears the same relation to the advance of physiology that the commissariat bears to the advance of an army

JEFFERSON MEDICAL COLLEGE

W M L COPLIN AND JOHN FUNKE.

This was the first time the Jefferson Medical College had contributed to the Scientific Exhibit Previous failure to participate was abundantly made amends for in the superb array of pathologic material presented on this occasion Professor Welch characterized it as the finest collection he had ever seen I desire formally to express my deep appreciation not only of this fine pathologic contribution, but of my great personal indebtedness to Professor Coplin for his assistance as a member of the committee in promoting and installing the Scientific Exhibit.

327 366 *Forty Typical Specimens Illustrating Renal Disease* —Including the various forms of nephritis and surgical lesions—hydronephrosis nephrolithiasis. pyonephrosis hypernephroma, congenital cystic disease etc. This series was formally demonstrated by Professor Coplin as part of the official program.

367 391 *Twenty-five Specimens Illustrating Diseases of the Lung* —Including various stages of croupous pneumonia. different phases of tuberculosis from acute miliary to chronic fibroid. These were exhibited in special jars designed by Professor Coplin

392-402 *Specimens Illustrating Problems in Comparative Pathology* —Permanently mounted in fluid. Including tumor from liver of horse, some lesions in lungs and other viscera of the lower animals

403-417 *A Series of Fifteen Embryos* mounted in gelatin under watch glasses They were intended more for demonstration of this method of exhibiting embryologic specimens than for the purpose of illustrating any special subject in embryology They were prepared by H F Radasch, demonstrator of histology in the Jefferson Medical College

418-482 *A Series of Sixty five Specimens* mounted by a new gelatin method intended to illustrate special methods in the final observation and orientation of material for teaching morbid anatomy and illustrating the following subjects (a) Typhoid Fever ulcers. (b) Intestinal Tuberculosis secondary ulcers (c) Brains, showing secondary tumors and various phases of meningitis. (d) Kidneys exhibiting typhoidal nephritis typhoidal pyelitis suppurative nephritis. chronic interstitial nephritis etc. (e) Lungs showing different stages of croupous pneumonia catarrhal pneumonia etc (f) Lungs showing metastatic sarcoma. (g) Lungs, showing various phases of tuberculosis (h) Arteries. showing arteriosclerosis thrombo arteritis etc (i) Glands from Hodgkin's disease (j) Stomach showing multiple erosions and another specimen of gastric ulcer loaned by Dr A. O J Kelly

JOHNS HOPKINS UNIVERSITY

WILLIAM H WELCH AND W G M'CALLUM

The Association is deeply indebted to the department of pathology of this institution for its loyal and liberal support of the Scientific Exhibit At every meeting since its inauguration the university has sent complete specimen groups, illustrative of some topic prominently considered in the sections A year ago fibroid tumors and amebic dysentery with its sequellæ were illustrated, this year arteriosclerosis Professor Welch demonstrated the latter series formally as part of the official program This added to the completeness of the symposium on the subject presented in the Section on Practice

483 *Dissecting Aneurism of Aorta*
484 *Traumatic Dissecting Aneurism*
485 *Atheroma and Aneurismal Dilatation of Aorta*
486 *Arteriosclerosis of Aorta with Calcification*
487 *Arteriosclerosis Atheromatous Ulceration and Calcification*
488 *Fresh Diffuse Arteriosclerosis of Aorta* Case of typhoid fever
489 *Arteriosclerosis, Calcification and Ulceration of Sclerotic Plaques*
490 *Arteriosclerosis* and occlusion of anterior descending coronary artery chronic fibrous myocarditis aneurismal dilatation of apex of left ventricle thrombus formation
491 *Arteriosclerosis of Aorta* Cardiac Hypertrophy
492 *Extreme Deforming Arteriosclerosis of Aorta*
493 *Localized Arteriosclerosis of Aorta*
494 *Arteriosclerosis* Chronic Mitral Endocarditis
495 *Fresh Disseminated Arteriosclerosis of Aorta*
496 *Arteriosclerosis of Aorta* with dilatation and thrombus formation
497 *Arteriosclerosis of Aorta*, thrombus formed on arteriosclerotic ulcer
498 *Extreme Arteriosclerosis of Aorta* with Calcification

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL

WINFIELD S HALL

This institution has contributed each year some new apparatus employed in research work in physiology This is highly creditable to the department and has been greatly appreciated in the Scientific Exhibit Professor Hall demonstrated the following apparatus as part of the official program An article fully descriptive of these will appear in a later issue of THE JOURNAL.

499 *Apparatus to Determine the Index of Refraction of Water or of Glass*
500 *Apparatus to Determine the Focal Distance of a Lens*
501 *To Map the Fields of Indirect Vision* for Form and Color

MEDICAL COLLEGE OF INDIANA, UNIVERSITY OF INDIANAPOLIS

FRANK B WYNN AND HELENE KNABE

1 RESEARCH GROUP

These specimens were obtained from an inspection of the suprarenal glands in 11,000 head of cattle They were all gelatin preparations mounted uniquely in plate glass boxes The latter were fitted in heavy oak frames in order to permit handling without danger of breakage

502 505 *Supernumerary Adrenals*—Found rather frequently in the ox and connected more or less intimately with the main gland

506 509 *Hemolymph Nodes*—These are often found intimately connected with the capsule of the adrenals and although generally much darker may have the same color and from gross inspection might be mistaken for accessory adrenals This series was shown for purposes of comparison with the preceding series

510 516 *Extensive Black Pigmentation of Adrenals*

517 520 *Similar Black Pigmentation of Hemolymph Nodes in Ox*

521 537 *Series of Seventeen Tumors of the Adrenals*—They varied in size from a cherry to the fetal head exhibited extensive black brown and orange pigmentation and extensive calcareous infiltration These neoplasms were mostly sarcomata A microscopic study of each is now in progress

These were all gelatin preparations in Petri dishes set by sixes in heavy oak boards from which they were readily removable They were designed by Dr Wynn for purposes of class demonstration

2 MISCELLANEOUS GROUP

538 552 Series of *Tuberculous Specimens*—(a) Lungs showing acute miliary type caseous pneumonia chronic apical lesions with abscess formation fibroid phthisis etc (b) Liver miliary form (c) Kidney acute miliary and chronic types (d) Spleen miliary form (e) Lymph nodes caseation and acute invasion (f) Pancreas acute miliary type

553 557 *Cancer Series*—Designed to show especially metastasis in the liver spleen and kidney

558 567 *Liver Series*—Illustrating alcoholic and biliary cirrhosis, passive congestion, fatty infiltration, etc

MEDICO CHIRURGICAL COLLEGE

(A) MICROSCOPIC EXHIBIT JOSEPH M'FARLAND AND GUTHRIE M'CONNELL

568 617 This was the only microscopic exhibit The sections were well prepared and each microscope was accompanied by an explanatory card or drawing The demonstrations of those in charge added greatly to the effectiveness of the series, which was designed to show Excessive cellular activity, edema, hyperemia, lymph metastasis lymphogenic extension impregnation of blood vessels cellular thrombosis cellular embolism and other conditions in the primary seat of disease predisposing to metastasis There were also a number of specimens showing how secondary tumors develop from lymphovascular and blood vascular emboli.

(B) GROSS PATHOLOGIC EXHIBIT JUDSON DALAND

This was a very complete heart and vascular series For the purpose of close inspection the specimens were exposed on platters

618 623 *Arteriosclerotic Series*—Showing obstruction of the coronaries with secondary myocardial changes fibrous thickening of the aortic valves atheromatous changes and tendency to aneurismal dilatation of the ascending aortic arch

624-627 *Series of Lesions of Aortic Valves*—Showing varying degrees of chronic aortic valvulitis associated with left ventricular hypertrophy

628 *Diffuse Sclerotic and Calcareous Changes* which have led to pouching off the aorta deformed aortic and mitral leaflets, with stenosis at the latter orifice

629 631 *Acute Vegetative Mitral Endocarditis*

632 633 *Buttonhole Mitral*

634 *Pedunculated Growth on Mitral Leaflet*

635 636 *Mitral Stenosis Enormous Hypertrophy*

637 640 *Series Illustrating Extensive Hypertrophy and Dilatation*—Secondary to the various cardiac lesions

641 643 *Series Showing Fatty Degeneration* and fibrous changes of the myocardium

644 645 *Ulcerative Endocarditis*

646 652 *Series Illustrating the Various Types of Pericarditis* ranging from the bread and butter appearance of the acute fibrinous to the obliterating form

653 655 *Aneurism of Left Ventricular Wall*

656 660 *Series Illustrating Various Types Frequently Found in Aorta*

661 *Aneurism of Subclavian* treated by wiring and electrolysis

662 *Specimens from Same Case* (Dr Wood)—Showing thrombus of left external iliac and embolus lodged in left popliteal artery

663 667 *Miscellaneous Specimens*

UNIVERSITY OF PENNSYLVANIA

(1) LABORATORY OF SURGICAL PATHOLOGY CHARLES H FRAZIER AND GEORGE P MULLER.

668 718 *Fifty Water Color Pictures Enlarged Photomicrographs and Drawings* designed to show the method of teaching surgical pathology at this institution

They consisted of "pictorial groups" illustrating both microscopic and macroscopic phases of pathologic lesions The group illustrating mammary carcinoma included a photograph of the patient, a water color of the breast in cross section after removal and lastly photomicrographs and drawings to show histopathologic structure Each picture group was separately framed In the absence of Professor Frazier, Dr Muller demonstrated the collection, giving in detail the methods of teaching this subject at the university

The 'Pictorial Groups were as follows (a) Acute Catarrhal Appendicitis (b) Acute Interstitial and Ulcerative Appendicitis with and without perforation and concretion (c) Chronic Interstitial Appendicitis. (d) Chronic Interstitial and Obliterating Appendicitis (e) Mammary Gland Scirrhus Carcinoma (f) Mammary Gland Medullary Carcinoma (g) Mammary Gland Malignant Adenoma a type in which the form of the acini is preserved arising in this specimen from an outlying mammary lobule (h) Mammary Gland showing metastasis in lymph glands and the skin in extensive ulceration resulting from carcinoma (i) Mammary Gland recurrence at site of former incision carcinoma nodules in pectoral muscle (j) Mammary Gland adenoma intracanalicular papillary fibroma (k) Parenchymatous Goiter (l) Epithelioma of Lip (m) Carcinoma of the alveolar mucous membrane encircling inferior maxilla and resembling sarcoma of latter (n) Hypernephroma of Kidney (o) Periosteal Sarcoma, spindle celled (p) Medullary Sarcoma of Bone (q) Caries and Necrosis of Bone. (r) Repair of Bone After Fracture (s) Myxosarcoma in Popliteal Space

(2) WILLIAM PEPPER CLINICAL LABORATORY D J M'CARTHY

This very complete collection was confined entirely to the domain of neuropathology The specimens were placed in shallow open jars so exposed as to show the lesion to best advantage Accompanying pencil sketches were of great help to the observer in studying the specimens Dr McCarthy formally demonstrated the collection, which consisted of the following series

719 727 *Specimens Illustrating the Vascular Supply of the Brain* as determined by areas of softening due to obliterating endarteritis of the middle cerebral or its branches Specimens showed areas of softening distributed as follows (1) Broca's area and island of Reil Clinically there was pure motor aphasia (2) Angular gyrus (3) First and second tempero sphenoidal lobe (4) Ascending parietal (post central) gyrus—lower two thirds Early sis of arm and face (5) Ascending frontal gyrus Recent obliteration of vessel Sudden paralysis of arm face and to some extent of leg from hemorrhagic extravasation (6) Softening and atrophy in the entire area of distribution of middle cerebral (7 9) Softening following complete obliteration of the sylvian artery

728 729 *Specimens of Obliterating Endarteritis* of terminal branches of the posterior cerebral showing softening in (1) cuneus (2) fusiform and lingual lobe

730 731 *Obliteration of Basilar* with softening of (1) superior

surface of cerebellum (2) inferior third of medulla with destruction of fillet and pyramids

732 736. *Series Showing Multiple Areas of Softening* due to arterial disease

737 739 *Series of Lesions Due to Disease of Venous System of Brain* (1) Extensive venous thrombosis of the veins of Galen straight sinus lateral sinuses and venous sinuses supplying cerebellum (2) Infiltrating venous hemorrhage affecting internal capsule optic thalamus and caudate nucleus (3) Venous hemorrhage limited to area of external capsule

740 741 *Lesions Secondary to Hemorrhage* before birth (1) Congenital absence of posterior third of right cerebral hemisphere Child died soon after birth Area between brain and dura was filled with a grumous fluid composed mainly of disorganized corpuscles (2) Extensive organized subdural hemorrhage covering the entire left half of brain of a five-months fetus Spontaneous abortion occurred while under observation in hospital

742 744 *Series of Aneurisms of Cerebral Arteries*

745 746 *Rupture of Cerebral Arteries*

747 750 *Hyaline and Pseudo Hyaline Exudates* into the Cerebral Ventricles

751 760 *Series of Brain Tumors* Endothelioma of left prefrontal lobe infiltrating the cortex Fibro sarcoma of left motor cortex Sarcoma of left leg center Sarcoma of left tempero-sphenoidal lobe Glioma of middle lobe of cerebellum Fibro sarcoma of left tempero-sphenoidal lobe Multiple sarcomata of brain Infiltrating sarcoma of tempero-sphenoidal lobe Myxo-sarcoma arising from choroid plexus—horse Endothelioma of lateral ventricle—horse

761 765 *Series Illustrating Tuberculosis of the Nervous System* Tuberculous meningitis with area of calcification Calcified area of tuberculosis of cerebellum Pachymeningitis externa—tuberculous Pachymeningitis interna—tuberculous Multiple tuberculous tumors of the brain one the size of a hazelnut on the left crus.

A number of the specimens shown were from the cases of Dr C W Burr at the Philadelphia Hospital, others were from the cases of Drs W S Wadsworth, J H Lloyd and W H Armstrong The remainder were from Dr McCarthy s cases

COLLEGE OF MEDICINE SYRACUSE UNIVERSITY

GAYLORD P CLARK

766-767 *Physiologic Models of the Nervous System*

These were designed by Dr Clark and are used in teaching the arrangement of the principal pathways of the nervous system They consist of serial sections made of wood representing typical sections of the spinal cord and brain enlarged twelve diameters, and painted to indicate the relative masses of gray and white matter Openings are cut in the white matter to correspond with the principal tracts of nerve fibers The sections are arranged one above another on a vertical support. The neurons are represented by colored cords, with knots tied either in one end or in the course of each cord, to indicate the cell body, and the ends are frayed to suggest the dendrites and terminal arborisations The colors are chosen to distinguish the afferent, ascending, descending and efferent fibers, the colors of the violet end of the spectrum being reserved for the first two sets, those of the red end for the last two, the brighter colors being used for the peripheral, the darker for the central fibers

In the absence of Dr Clark, Dr Busch demonstrated the method of using the models for teaching purposes

UNIVERSITY OF TEXAS DEPARTMENT OF MEDICINE

WILLIAM KEILLER

768-772 *Series of Five Wax Casts* to represent the surface appearance and progressive dissections of a case of cystic goiter

The casts were designed to place on record and demonstrate to students the complete surgical anatomy of a case of cystic enlargement of the thyroid gland which came to the dissecting room A plaster of Paris mold was taken of the bust and of each successive dissection The technic employed is as follows After allowing the mold to dry and cool, it is then moistened with water, banked up at the edge with putty and into it is poured a melted wax composed of equal bulks of hard paraffin, white wax and stearin (this may be tinted by adding a very little artist's oil color, say yellow ochre and carmine for a flesh tint) The melted wax is laved up on the side by means of a flat bristle paint brush the whole done slowly as the wax hardens After one-fourth of an inch is set on all parts of the mold it is backed and strengthened by narrow strips of burlap steeped in wax and overlying each other, to give the cast strength with the least thickness When the whole cast is about half an inch thick the mold and cast are immersed in cold water In two or three hours the cast will shrink slightly and become easily separable from the mold The cast is then, if necessary, partly carved and tinted with oil colors, the transparent colors being preferred as far as possible

773 *Leaden Specimen Tray or Box* for the preservation and demonstration of anatomic or pathologic wet specimens

It was designed by Dr Keiller and consists of a shallow leaden tray, set in a heavy oak frame and covered with glass, and with tubular inlet for admission of the preserving fluid

PHILADELPHIA GENERAL HOSPITAL

(A) GROSS MUSEUM SPECIMENS B C ROSENBERGER

This was, in the main, a heart collection, and there is probably no finer in the country The specimens were very carefully dissected, well preserved and the lesions skillfully exposed for inspection

774 779 *Series Illustrating of Pericarditis* showing beautifully the fibrinous fibrino purulent, hemorrhagic, villous and adherent types

780 807 *Endocarditis Series*—acute and chronic These showed varying degrees of stenosis and insufficiency of the mitral and aortic orifices Especially well illustrated were Vegetations—at different stages and of various sizes Ulcerative destruction of the leaflets Valvular fenestration Valvular deformities arising from sclerotic and calcareous changes.

708-810 *Series of Congenital Heart Anomalies* Communication between ventricles patulous ductus arteriosus Patulous foramen ovale one from a patient aged 72 years

812 813 *Aneurism of Left Ventricle*

814 *Organized Thrombus in Left Ventricle* extending into aorta

815 *Secondary Carcinomatous Nodules* in left ventricle

816 *Aneurism of Innominate Artery*

817 824 *Kidney Series* illustrating congenital cystic disease hydronephrosis nephrolithiasis and tuberculosis

(B) ROENTGEN RAY LABORATORY MIHRAN K KASSABIAN

825 1025 *Series of Skiagrams* made in the hospital and classified as follows (1) Foreign Bodies—In various parts of the body including bullets in the brain eye and methods of localization. (2) Fractures and Dislocations—These were of nearly every known variety and included several cases of congenital dislocations of the hip joint both before and after reduction by Professor Lorenz (3) Diseases of Bones and Joints—These included tuberculosis syphilis rachitis osteomalacia ostitis periostitis tumors and osseous diseases occurring in the course of nervous diseases as hemiplegia tabes dorsalis syringomyelia, etc. (4) Lung Diseases.—Phthisis in its various stages and the several varieties of pneumonia and pleurisy with effusion (5) Heart and Aorta—Hypertrophy dilatation and displacement of heart aortic aneurisms (6) Renal ureteral and vesical calculi (7) Brain tumors and cysts etc (8) Dental Cases—Unerupted teeth, necrosis, roots etc

1026-1125 *Transparencies*—These were made by camera and reduced to a uniform size (4x5) and placed in two frames illuminated through ground glass from the back These pictures showed more and sharper details than the prints and negatives.

1126 *Stereoscopic Apparatus*—This apparatus is unique producing a perspective or relief effect in the picture This relief effect is particularly valuable to the surgeon in diagnosing fractures and dislocations and foreign bodies as it shows the amount of overlapping of fragments extent and character of the dislocation and the exact location of foreign bodies.

1127 1167 *Photographs of Cases* under *x* ray treatment for malignant growths, skin diseases etc Dr Kassabian also exhibited a number of skiagrams from his private collection

PENNSYLVANIA HOSPITAL

WARFIELD T LONGCOPE

This collection was entirely in illustration of Hodgkin's disease Seven cases afforded the material of which Dr Longcope has made careful study He made a formal demonstration of the series as part of the official program

1168 *Case 1*—Photograph of the patient before death The specimens exhibited consisted of two huge wing like masses of enlarged lymph nodes extending on either side of the trachea also enlargement of the submaxillary sublingual superior mediastinal and retroperitoneal nodes and the axillary group on one side. Accompanying drawings represented the histologic appearance of the lymph nodes

1169 *Case 2*—Photograph showing typical appearance of the patient The specimen showed extensive enlargement of the cervical lymph nodes on each side of the retropharyngeal nodes and the submaxillary groups Reproductions from drawings to show histologic character

1170 *Case 3*—Enlargement only of a few lymph nodes on one side of the neck No involvement elsewhere

1171 *Case 4*—Enlargement of the retroperitoneal lymph nodes those along the iliac vessels and in the left inguinal region

1172 *Case 5*—Spleen in Hodgkin's disease Specimen shows extensive involvement of the organ by secondary nodules Reproductions from drawings to show the histologic changes in the lymphomatous nodules

1173 *Case 6*—Spleen from case of Hodgkin s disease presenting much the same appearance as the preceding

1174 *Hodgkin s Disease Lung*—The specimen demonstrated the mode of involvement of the lung by lymphomatous nodules The bronchial lymph glands were markedly involved.

Microscopic sections from various cases were shown to demonstrate the special phases of lesions

THE HENRY PHIPPS INSTITUTE

LAWRENCE F FLICK AND RANDLE C ROSENBERGER

This beautiful collection was highly creditable to the institution from whence it came

1175-1193 *Series Illustrating of Tuberculosis in Man*—The preparations illustrated well the following lesions Incipient apical tuberculosis—unmixed infection Ulcerative tuberculosis at the apex with complicating pneumonia at base Ulcerative type with recent hemorrhages Ulcerative form of secondary miliary invasion throughout lung Ulcerative form with peribronchial infiltration Cavity formation of all types, from those small in size to those occupying a whole lobe or the entire lung, cavities surrounded by thick fibrous walls Bronchiectasis associated with cavity formation Greatly thickened pleuræ associated with tuberculosis Tuberculous lesions of the intestines Tuberculous leptomeningitis

ZOOLOGICAL SOCIETY OF PHILADELPHIA

C Y WHITE

This exhibit was devoted to tuberculosis in the lower animals The specimens were beautiful Kaiserling preparations and were formally demonstrated by Dr White as part of the official program This collection together with the preceding made the exhibit of the lesions of tuberculosis in man and the lower animals very complete

1194 1196 —*Tuberculosis in Cattle*—The specimens showed the early, moderate and advanced lesions of 'grape disease' of the pleura in cattle

1197 *Tuberculosis of the Liver from a Nyghalae Deer*—The specimen showed well the chronic fibro-caseous form often seen in herbivora

1198 *Tuberculosis of Lungs of a Goat*

1199 *Tuberculosis of Lungs of a Bear*—The two preceding specimens showed the lesions of the lungs often observed in carnivorous animals, i e, widespread tuberculosis with the formation of cavities

1200 *Tuberculosis of Lungs in a Lemur*—The whole of one lung showed an acute tubercular pneumonia

1201-1212 *Series of Tuberculous Spleens from Monkeys*—The various stages of the tuberculous process were beautifully shown In some of the organs were pinhead sized tubercles others contained nodules the size of a cherry or walnut One spleen showed almost complete caseation.

1213 1214 *Tuberculosis of Spleen in Children*—These were exhibited for purposes of comparison with the tuberculous spleen in monkeys. The similarity is striking

1215 1223 *Generalized Tuberculosis in Monkeys*—All organs were shown in various stages of the tuberculous process

INDIANA STATE MEDICAL SOCIETY

FRANK B WYNN

This society enjoys the distinction of being the parent of the Scientific Exhibit idea The organization has not only maintained its own annual exhibit of this character for the past seven years, but has been a contributor to the exhibit of the Association the year before and every year since the Scientific Exhibit was inaugurated

1224 *Specimen of Cor Bovinum*—Weight in fresh state 1 544 grams Incompetence of mitral leaflets The patient had taken forty five minim doses of tincture of digitalis four times daily for a long period with marked benefit in relief of symptoms. This may have had something to do with the enormous hypertrophy Case of Dr Wynn

1225 *Tuberculous Pericarditis*—Of long standing as indicated by thick fibrous walls (measuring a centimeter at points) Adhesions finally broken down by extensive caseation involving the entire cardiac surface Great hypertrophy Case of Dr Guido Bell

1226 *Large Myxofibromatous Polyp*, one by three inches in dimensions attached one inch above the ileocecal valve, and protruding into the cecum Death occurred with symptoms of obstruction Operation refused Case of Dr L A Hyde.

1227 *Myxofibromatous Polyp of Stomach*—Two inches in length by a half in diameter Attachment one inch from pyloric constriction Polyp deflected and protruded into pylorus producing uncontrollable vomiting and death Case of Dr E Wishard

1228. *Round-Celled Sarcoma* the size of a walnut in the intestinal wall surrounded the opening of the common duct and produced extreme icterus Metastases in liver Case of Dr Sexton

1229-1233 *Series Showing Very Typical Arteriosclerotic Changes* in the splenic artery coronary vessels, aorta, mitral and aortic valves

1234 1239 *Series of Pedunculated Masses* obtained from the abdomen of the ox They are produced by torsion, no doubt from the peristaltic movement of the intestines The masses contained fat, fibrous and necrotic tissue, some of which were infiltrated with lime

GOVERNMENT HOSPITAL FOR THE INSANE

I W BLACKBURN

This exhibit was intended primarily to show the exhibitor's methods of photographing pathologic specimens, coloring the same, and the making of bromid enlargements for exhibition and teaching purposes Crayon work on these enlargements with the object of subsequent half tone or photo lithographic reproduction for book illustration, was a feature of the work The photographs exhibited showed a large variety of gross pathologic lesions of the brain and other organs, associated with cases of mental disease Cerebral arteriosclerosis was illustrated by numerous carefully prepared dissections reproduced by photographs and bromid enlargements This is the third year that Dr Blackburn has contributed to the Scientific Exhibit Those who witnessed his formal demonstration of this artistic collection thoroughly enjoyed it The exhibit consisted of the following

1240 1263 *Bromid Enlargements* of various pathologic subjects

1264 1343 *Eighty Colored Photographs* showing the exhibitor's method of using color in the preparation of subjects for book illustration

1344 1418 *Seventy five Photographs* of pathologic subjects illustrating gross lesions of the brain and other organs associated with mental disease

1419 1426 *Series of Wax Brain Casts* Prepared by the exhibitor's method

UNITED STATES BUREAU OF CHEMISTRY

H W WILEY

This exhibit was in illustration of food adulteration, especially of imported food products The demonstration of Dr Wiley, as part of the official program, was made very practical and interesting The following articles were shown

1427 1466 *Samples of Food Adulterations* especially of imported food products They included the following Olive oil adulterated with cotton seed oil Olive oil adulterated with 15 per cent peanut oil Olive oil adulterated with cotton seed oil and mislabeled as to size of bottle. Strawberry pulp containing salicylic acid and benzoic acid Egg albumin preserved with salicylic acid. Fruit juice preserved with salicylic acid Strawberry preserves colored with coal tar dye Strawberry preserves colored with cochineal German sausage preserved with benzoic acid. German sausage preserved with boric acid, the use of which is prohibited by German law German sausage preserved with aluminium acetate Strawberry preserves colored with anilin dye, and preserved with salicylic acid Rhine wine preserved with salicylic acid Grecian wine preserved with salicylic acid Orangeade labeled as containing benzoic acid and being colored. Jam labeled as containing benzoic acid and glucose Misbranded cherries contains no creme de menthe colored with an anilin dye Alleged vegetable color showing a method of labeling Artificial vinegar colored with anilin dye and preserved with salicylic acid Maraschino cherries colored with anilin dye Fruit syrup adulterated with glucose Ginger ale preserved with benzoic acid Tomato catsup preserved with benzoic acid Orangeade colored with anilin dye and preserved with salicylic acid Alleged vegetable color containing coaltar dye. Alleged vegetable color showing method of relabeling Sauterne wine containing 460 milligrams of sulphurous acid per liter of which 125 milligrams are free Sauterne wine preserved with salicylic acid. Sauterne wine containing 500 milligrams of sulphurous acid per liter of which 110 milligrams are free Sauterne wine containing 400 milligrams of sulphurous acid per liter, of which 80 milligrams are free

WILLIAM G SPILLER PHILADELPHIA (PRIVATE COLLECTION)

This collection was a beautiful series of brain specimens illustrating various forms and situations of tumors of that organ Among these were glioma, endothelioma, sarcoma, carcinoma and fibroma Dr Spiller made an interesting formal demonstration of the collection

1467 *Metastatic Carcinoma* surrounding the optic chiasm and extending into one orbit.

1468 *Endothelioma* growing from the dura The underlying cortex was found much atrophied

1469 *Large Fibroma of the Cerebello pontile Angle*, implicating the acoustic and facial nerves

1470 *Fibroma of Cerebello pontile Angle*, causing internal hydrocephalus

1471 *Specimen of Meningitis in Plaques*—Tuberculosis plaques, flat, adherent and confined largely to one parietal lobe and giving the symptoms of brain tumor This is a very rare form of tuberculosis and does not seem to have attracted attention in this country

1472 *A Brain Showing Arrest of Development* of the cerebral hemisphere of one side and of the cerebellar hemisphere of the opposite side.

JAY F SCHAMBERG PHILADELPHIA (PRIVATE COLLECTION)

This excellent collection of photographs of dermatological cases was arranged in two groups illustrative respectively of smallpox and cutaneous syphilis

1473 1502 *Series of Photographs Illustrating Smallpox Eruptions*

(1-4) An unvaccinated lad showing eruption on the fourth, eighth and eleventh days and after recovery

(5 10) Six serial photographs exhibiting the evolution of the smallpox lesions Photographs show patient on the fourth sixth seventh ninth and fourteenth days of eruption and after recovery

(11 12) Smallpox in unvaccinated mulatto Eruption extensive but not deep seated in the skin, hence but slight scarring Eyelids and features tumefied

(13) Severe case showing characteristic distribution of the eruption Face completely covered with confluent lesions, extremities profusely attacked, comparative sparsity of lesions on the abdomen

(14 15) These showed the large hemispheric pustules such as are often seen in unvaccinated subjects.

(16) Smallpox in unvaccinated girl of 14 Lesions on the arms exhibited the so called secondary umbilication due to partial collapse of the pustules and sinking in of the centers

(17) Photographs representing mild and severe attacks in two unvaccinated children In the mild case the lesions were discrete in the other confluent producing swollen and distorted features The latter patient succumbed

(18) Well pronounced discrete smallpox in a girl of 16 The lesions were confluent in clusters due to slight abrasions and congestion of the skin at points previous to the attack

(19) Hemorrhagic smallpox of the purpuric variety The patient a pregnant woman, contracted the disease from a mild at

tack in her father in law the nature of which was not suspected She gave birth to a living child at term and expired a few days afterward The eruption consisted of pinhead sized petechiæ covering the entire body with here and there larger ecchymoses

(20) Infant of patient with hemorrhagic smallpox The disease was contracted in utero and the eruption appeared on the ninth day after birth The child was vaccinated on the second day A tardy vaccine vesicle appeared but it was not sufficient to prevent the development of fatal smallpox.

(21 22) Two cases of discrete smallpox one in an unvaccinated young man the other in an old man not vaccinated since infancy The lesions in the former were large full pustules In the vaccinated patient they were distinctly modified Vesiculation and pustulation were rapid crusting soon took place and the crusts dropped off in a week These cases run a very rapid course and when the modification is pronounced may offer considerable difficulty in diagnosis.

(23) Smallpox in child of 6 showing confluent blackish crusts covering the entire face and presenting a most hideous appearance The patient was neglected at home and the blackish mask over the face resulted from the drying of the pustular contents of ruptured lesions and the admixture of dirt.

(24) Case showing the profusion of lesions on the hands in severe case of smallpox. The hands become swollen, painful and a source of great distress to the sufferer

(25) Soles of the feet shown with the epidermal excavations left after the removal of the inspissated pocks Patients while away their convalescence by digging out with a penknife the encapsulated lesions of the palms and soles.

(26) Extensive scarring of the face and baldness following a severe attack of smallpox Also lost an eye from severe corneal ulceration.

(27) Extensive pigmentation of the body over the areas occupied by the variolous lesions. After an attack of smallpox the sites of the lesions remain red for several months and in persons of swarthy complexion they may later assume a café au lait tint

(28) Abscessed eyeball from corneal ulcer

(29) Gangrene of skin of thigh during third week of attack Recovery

1503 1517 *Series of Photographs in Illustration of Cutaneous Syphilis*

(1) Photograph showing a large chancre of the chin in a young woman who worked in a laundry in a disreputable neighborhood The lesion is alleged to have resulted from scratching an acne lesion after having handled linen soiled with discharges

(2) Maculo-papular syphilide of the face in a woman following the roseola

(3) Severe papulo-tubercular syphilide most prominent on the face Patient had early symptoms of meningeal involvement but recovered under vigorous treatment.

(4) Generalized papulo-pustular syphilide of the varioloform type. Patient was sent to the Municipal Hospital as a case of smallpox. Fortunately, she was promptly vaccinated and protected against smallpox.

(5) Acneiform syphilide involving the face trunk and extremities This patient had a long standing acne, and it was difficult to tell which of the facial lesions were acne and which were syphilitic.

(6-7) Extensive annulo-papular syphilide on the face of a colored girl This variety of syphilide is much more common in negroes than whites

(8) Large papular syphilide which during the epidemic prevalence of smallpox was suspected of being variolous

(9) Case of syphilide sent to the Municipal Hospital as smallpox, and completely deceived two professors in one of the medical schools. The patient later developed ulcerated lesions on the skin and in the throat and almost perished

(10) Types of circinate squamous syphiloderm on the palms of the hands.

(11) Ulcerative syphilide on the lateral aspects of the heel of six months duration

(12) Tubercular ulcerating syphilide of the face in a woman who grossly neglected early treatment.

(13) Hutchinson s teeth in a child with hereditary syphilis The test teeth are the upper central incisors These were crescentically notched and distinctly peg-shaped

(14) Syphilitic dactylitis in a young man 19 years of age with hereditary syphilis.

(15) From same patient as preceding and showing gumma projecting from the forehead

J W DRAPER MAURY NEW YORK (PRIVATE COLLECTION)

This exhibit represented research work from the department of surgical pathology at Columbia University The collection was demonstrated by Dr Maury in connection with his paper before the Section on Surgery, on "Twine in Lieu of the Elastic Ligature for Performing Gastroenterostomy"

1518-1527 *Series of Gastroenterostomies Performed on Dogs and a Pig*—These experiments seemed to prove the advantage of twine over the elastic ligature Twine cuts through when inserted by the triangular stitch as a result of deprivation necrosis while the elastic stitch as inserted by Dr McGraw cuts through by simple pressure.

F C BUSCH BUFFALO (PRIVATE EXHIBIT)

1528-1530 *Series Showing Successful Grafting of the Suprarenal in the Kidney of a Rabbit*

The grafts apparently carried on the suprarenal function after all other suprarenal tissue had been removed These specimens were demonstrated by Dr Busch as part of the official program

MYRON METZENBAUM CLEVELAND (PRIVATE EXHIBIT)

1531 1580 *Pictures Representing the Results of Typical Experiments with Radium* thorium uranium pitchblend and other radioactive substances, and showing their action on photographic plates

Some pictures were shown indicating the effect of metallic aluminium on photographic plates Photographs were shown of a case of very extensive lupus healed by the aid of radium after the case had been treated unsuccessfully for a year with the *x*-rays.

JOHN G WILSON, MONTROSE, PA (PRIVATE EXHIBIT)

1581 *Radiogram* of the hand and forearm

1582 *Radiogram* of shoulder, showing fracture of the surgical neck of the humerus.

These were remarkably clear and perfect *x* ray pictures

The Public Service.

Army Changes

Memorandum of changes of stations and duties of medical officers U S Army, week ending Sept. 10 1904

Gregory Junius C, asst surgeon reports for temporary duty at Fort Miley, Cal

Godfrey G C M asst surgeon, granted seven days' leave of absence

Reilly, John J, asst surgeon sick leave of absence extended thirty days

Rockhill Edward P asst. surgeon ordered to proceed from Presidio of San Francisco to Fort Miley Cal, for temporary duty

Mabray, William C contract surgeon, granted one month s leave of absence from Sept 4, 1904

Navy Changes.

Changes in the medical corps U S Navy for the week ending Sept 10, 1904

Urie J F, surgeon detached from the *Missouri* and granted sick leave for three months

Drake N H, surgeon, detached from the *Lancaster* and ordered to the *Hancock*

Guest M S P A surgeon, ordered to the *Lancaster*

DeValin C M P A surgeon unexpired portion of leave revoked ordered to duty at the Naval Hospital Philadelphia

Marine-Hospital Service

Official list of the changes of station and duties of commissioned and non commissioned officers of the Public Health and Marine Hospital Service for the seven days ending Sept. 7, 1904

Brooks D D surgeon, granted leave of absence for thirty days from Sept. 2 on account of sickness

Hobdy W C P A surgeon, granted leave of absence for seven days from Aug 20 1904, under the provisions of Paragraph 191 of the Regulations.

Kerr J W P A surgeon, granted leave of absence for four days from Sept. 5, 1904 in accordance with the provisions of Paragraph 191 of the Regulations

Robinson D E P A. surgeon granted leave of absence for two days from Sept 6, 1904, under the provisions of Paragraph 191 of the Regulations

Hunt Reid pharmacologist detailed to represent the service at meeting of American Pharmaceutical Association at Kansas City Mo Sept. 5 10 1904

Ballard J C A. A surgeon, granted leave of abence for seven days from Sept 5 1904

Mackall P McV A. A surgeon, granted leave of abence for seven days under the provisions of Paragraph 210 of the Regulations

Roehrig A M pharmacist, granted leave of absence for thirty days from Sept 12 1904

Stearns W L pharmacist, granted leave of absence for twenty nine days from Sept. 6 1904

O Gorman T V pharmacist, department letter of Aug 10 1904 granting leave of absence for thirty days from Aug 18, 1904 amended so that said leave shall be effective from Aug 24 1904

La Grange J V pharmacist granted leave of absence for twenty three days from Sept 15 1904

Holsendorf B F pharmacist, department letter of Aug 6 1904 granting leave of absence for thirty days from Sept. 1 1904 amended so that said leave shall be for twenty four days only

BOARD CONVENED

Board convened to meet at Washington D C Oct 3 1904, for the examination of candidates for appointment as assistant surgeon in the service Detail for the board Surgeon W P McIntosh chairman Surgeon G M Guiteras P A Surgeon John F Anderson recorder

PROMOTIONS

Assistant Surgeon D H Currie commissioned as P A surgeon, to rank as such from July 28, 1904

Assistant Surgeon J M Holt commissioned as P A surgeon to rank as such from July 27 1904

Assistant Surgeon F E. Trotter commissioned as P A surgeon to rank as such from July 27 1904

Health Reports.

The following cases of smallpox, yellow fever cholera and plague have been reported to the Surgeon General Public Health and Marine-Hospital Service during the week ended Sept. 9, 1904

SMALLPOX—UNITED STATES

District of Columbia Washington Aug 27 Sept. 3 1 case

Florida Jacksonville Aug 27 Sept. 3, 1 case

Illinois Chicago Aug 27 Sept 3 5 cases

Louisiana New Orleans Aug 27 Sept. 3 4 cases, 1 case imported

Massachusetts Aug 27 Sept 3 Lawrence 1 case, North Adams 22 cases, 1 death

Michigan At 51 localities Aug 20 27 present

Ohio Cincinnati Aug 19 26 1 case

Pennsylvania Aug 27 Sept. 3 Philadelphia 1 case Williamsport 1 case

Tennessee Aug 27 Sept 3 Memphis 1 case Nashville 3 cases

SMALLPOX—FOREIGN

Brazil Rio de Janeiro, July 24 Aug 7 549 cases, 210 deaths
Canada Winnipeg Aug 13 20 1 case
France Paris, Aug 13 20, 8 cases, 1 death
Great Britain Glasgow Aug 19 26 2 cases Aug 13 20, London, 2 cases, Nottingham 2 cases, Manchester, Aug 6 20 6 cases
India Bombay, Aug 2 9, 8 cases, Karachi July 31 Aug 7, 3 cases
Italy Palermo Aug 13 20, 37 cases, 4 deaths
Mexico City of Mexico, Aug 14 21 12 cases

CALIFORNIA ACADEMY OF MEDICINE

Meeting held in San Francisco, Aug 23, 1904

The President, Dr T W Huntington, in the Chair

Bacterial Etiology of Gallstones

DR LARTIGAU described his experimental studies on the production of gallstones At least two important conditions must be fulfilled in order to produce gallstones experimentally In the first place it is necessary to infect the bile passages with organisms of low virulence, for if virulent organisms are used a serious infection results, but no gallstones are produced The second factor necessary is an obstruction to the outflow of bile, for without this no gallstones will result from the infection By complying with these two conditions Dr Lartigau was able to produce gallstones by infections with a variety of organisms, among them the colon bacillus, the typhoid bacillus, the hog cholera bacillus, the bacillus pyocyaneus, staphylococci, and even tubercle bacilli Stagnation of the bile was produced by placing bits of cotton in the mouth of the gall bladder and by partially ligating the duct It made little difference which organism was used provided the above named conditions were complied with, but it seemed as if the motile bacteria were more likely to give rise to stones Pure cultures and mixed cultures were equally effective The shortest time necessary to produce a stone was six weeks, but usually it took from four to twelve months The longer the time, the larger was the stone The reaction of the bile made but little difference After infection the bile became more watery and of a lighter color No relation could be discovered between the nature of the infection and the chemical character of the stone The introduction of sterile material such as silk or sand did not give rise to gallstones It seems probable that the infection in man is by way of the portal vein and not through an ascending infection of the biliary passages A number of facts favor this view Adami and Ford have elaborated the theory that there is a constant passage of bacteria through the mucosa of the intestines The bacteria of cholecystitis are not those commonly found in the duodenum If the common duct be tied, we get an infection of the bile passages Finally, if an enteritis be caused by the administration of arsenic or bichlorid of mercury, and if then the animal is fed with some easily recognized organism, as the *Bacillus prodigiosus*, this organism may be found in the bile passages From a consideration of these facts it seems not only possible, but probable, that the infection of the gall bladder in man is by way of the portal vein

DISCUSSION

DR W W KERR asked What is the condition of the wall of the gall bladder in these experimental animals? Is it not possible that carcinoma of the biliary passages might give rise to gallstones? It would produce the necessary stasis and the diseased condition of the wall might favor the formation of stones The ordinary duration of a carcinoma would also allow time for the formation of stones Cholesterin stones are probably produced by a perverted secretion of the mucous membrane of the gall bladder

DR GEORGE BLUMER mentioned Cushing's suggestion that agglutinated clumps of typhoid bacilli might form the nuclei of gallstones, and asked if there was any evidence of such a process in the present series of experiments Human stones differ from those produced experimentally in that they are present in very great numbers in most cases, and all the stones seem to be of about the same size

DR HUNTINGTON asked if normal bile is sterile The stasis is an important factor in the infection of such a series of tubes as the bile passages It has been shown, for example, that the injection of virulent bacteria into the normal appendix is without effect, whereas if the appendix be ligated a severe appendicitis will result Recurrence after the removal of gall stones is not very common According to Mayo, it occurs in from 5 to 6 per cent of all cases

DR. LARTIGAU stated that the gall bladders in his animals showed a thickened mucous membrane, with some cicatricial tissue and some necrosis Many gall bladders containing stones show adenomatous growths resembling carcinomata He was not prepared to say what effect the agglutination of bacilli might have on the formation of gallstones As is the case with many other fluids in the body, ordinary cultures made from the bile are usually sterile, but by special methods, using large quantities of bile in large amounts of bouillon, a few organisms can usually be demonstrated to be present even in normal bile

Maldevelopment of the Ear

DR C M COOPER exhibited a young man who complained of dizziness The left external ear was small and deformed, the external auditory canal closed In such cases the middle and internal ears also are usually poorly or not at all developed In this case, however, the eustachian canal is open and the middle ear can be inflated An examination with the *x* ray shows the presence of the semicircular canals and a fully developed mastoid bone The right side of the tongue is somewhat smaller than the left, and when protruded the tongue deviates somewhat to the right The right side of the palate is paretic The posterior cervical glands are enlarged The condition is probably due to a congenital syphilis

DR STAPLER asked about the possibility of the deformity of the ear being a sign of degeneracy The general intelligence of the patient should be examined and his family antecedents gone into

DR COOPER stated that the boy was quite bright and that the paresis in his mouth was typical of congenital syphilis

A New Method of Examination with the X-Ray

DR C M COOPER described a new method of examining the abdomen with the *x* ray The patient lies face downward on a piece of canvas and the *x* ray is placed beneath him The colon is then blown up with gas and at the same time he is exam ined with the fluoroscope By this method the spleen and kidneys can be seen and tumors of these organs differentiated from those of neighboring organs

Dr H C Moffitt stated that he could confirm the value of Dr Cooper's method He believed it more satisfactory than the older method of distending the colon and then using percussion to differentiate the spleen from the kidney It may prove of great service in the examination of the left hypochondrium

THE OBSTETRICAL SOCIETY OF PHILADELPHIA

Regular Meeting, June 2, 1904

The President, Dr Richard C Norris, in the Chair

Report of a Case of Ovarian Cyst with Retained Menstrual Blood

Dr. Marie K. Formad reported a patient, 45 years of age, single, who had never menstruated and always had a large abdomen, but suffered no discomfort nor pain from it Six or seven weeks before coming to the hospital she noticed that the abdomen became rapidly larger and the skin tense Her feet began to swell, and she had dyspnea when going upstairs Otherwise she felt well and worked at her trade, that of an operator in a hosiery mill, until three days before she entered the hospital, April 28, 1904 Abdominal inspection showed enlargement of the abdomen, most prominent on the left side, dullness on percussion to and above the umbilicus On palpation, the mass fluctuated, fluid seemed to be encysted, as there was no bulging in flanks, nor change in location of tumor with patient in different positions The right side was tympanitic to median line below the umbilicus The vaginal examination showed vagina very short, absence of cervix Bulging of both fornices. Uterus not palpable. A clinical diagnosis was made of bicornate uterus with retained menstrual secretion Correct diagnosis Multilocular ovarian cyst Complete congenital atresia of the uterus Left horn of uterus was dilated and ran out into the fallopian tube and directly passed into a single loculus of the multilocular cyst Right tube ended in blind extremity In the cornu just outside of the occlusion a tubal calculus was found

DISCUSSION

Dr. L. J Hammond—This very instructive case is the exception, not the rule, in ovarian cystoma, the typical fluid found being characteristically straw colored This chocolate colored content is not uncommonly found in the broad ligament cysts of the paroöphoritic type It is instructive, therefore, to note this condition of papillomatous change existing in ovarian cysts These masses, as described in this specimen, might readily account for the blood mixed fluid found in such large quantity in the cyst

Dr Formad—This is not a broad ligament cyst, but an ovarian cyst This was shown by the microscopic examination

The Ultimate Results of Induced Labor for Minor Degrees of Pelvic Contraction.

Dr. Richard C Norris read a paper reporting in detail thirty cases with their results, for mother and child, the degrees of contraction varying in the conjugate diameters between 8 and 10 cm There was neither maternal mortality nor morbidity The infantile mortality was 10 per cent after following the histories of the children subsequent to their leaving the hospital Dr Norris took issue with those who recommend hasty cesarean section for these grades of deformity He quoted Williams' statement that hardly more than 50 per cent of the infants survive the first few months of life, and said that that statement could only be true of induced labors for high grades of contraction, a field no longer to be tested by induced labor, but by the elective cesarean section. He also referred to Reynolds' statement that cesarean section is indicated when with any definite pelvic contraction there is a history of repeated child births during previous operative labors and for healthy primiparæ with conjugates between three and four inches, that the amount of difficulty which will occur should be estimated by observations of the progress of labor, but that the possibility that an indication for the cesarean section may arise should always be borne in mind in such a case, and that all the preparations for it should be made beforehand, or at least during the first stage of labor Norris referred to his tables and asserted that it was in just such cases that his best results were obtained by induction of labor, not more than four weeks, and usually two weeks before term The assistance given Nature by skillful induced labor, and the employment of the Trendelenburg Welcher posture, had repeatedly avoided the necessity for a difficult operative delivery which ordinarily gives the high fetal mortality He discussed the difficulties of accurate estimation of the duration of pregnancy and outlined the plan he followed to eliminate, so far as possible, the induction of labor at too early or too late a period of pregnancy An analysis of his tables of thirty cases was presented and a plea made for the adoption of this method of treatment in place of the hasty and oftentimes spectacular cesarean section which, in his judgment, had sometimes been an exhibition of experimental and unnecessary surgery

DISCUSSION

Dr George M Boyd—While Reynolds may do a long series of cesarean sections, and Norris still another series of induction of premature labor without death, we do have cases of death from cesarean section and from induction of premature labor Dr Norris is to be congratulated on his results, which show a much lower fetal mortality than many of us have enjoyed. It has been the high fetal mortality which has caused many to refrain from performing the induction of premature labor In my own experience in the Lying in Charity for fifteen years, I confess that I have only in exceptional cases resorted to induction of labor, because of my inability to measure the length of gestation It seems to me there must almost always exist a latitude of two or three weeks, and it is just that latitude which makes the operation uncertain If the operation is of any real benefit it must be done sufficiently early Then again, some patients will go into labor right after the introduction of one or two bougies, and other patients not until after many hours In some cases I have seen the unfortunate rupture of the membranes with the best operators There is some danger also of striking the placental site, and some slight danger from infection, so that fearing the early rupture of the membranes, I have preferred to allow my patients to go to term I feel that the only really accurate way of measuring the pelvis is by the test of labor and noting whether the head is or is not adapting itself to the birth canal So far as my experience goes I feel that the patient would be best served by permitting her to go to term, and after the test of labor, resorting to the operative measures that seem best indicated.

Dr Daniel Longaker—It seems to me that the indications for this particular operation are clearly set forth in limiting the induction of premature labor to the lesser degrees of pelvic contraction Going back some considerable time in my own experience, I remember different cases in which the operation of induced premature labor was ill advisedly applied to degrees of pelvic narrowing which were entirely too great to permit of even the safe delivery of a child that had only reached the twenty eighth week of gestation For instance, a child that had not attained a weight of more than five and a half pounds and, as nearly as we could determine, a period of gestation of from twenty eight to thirty weeks, with a difficult extraction in a woman whose direct conjugate was estimated to be 7½ cm, or a little under, too great a degree of contraction to permit safe extraction, and the child had to be delivered by version If one selects the operation for that class of cases it must fall into disrepute That particular woman was safely delivered twice after that by symphysectomy of a living baby of large size at term The cases in which induced premature labor will have brilliant results are the lesser degrees of contraction, the direct conjugate being not under 8 cm I do not know whether I am correct in my conclusion, but my impression is that in these cases there is a tendency, for some reason which I do not care to discuss to protracted gestation I have knowledge of cases which have been carefully studied in which the gestation has gone to almost 300 days, 28 to 30 days beyond the computed time, and where the size of the child was an additional evidence that it had been carried beyond the average time. I think that where we have reason to know from external measurements, and from the history of preceding labors that there is pelvic contraction, it behooves us to watch the case with extreme care and to estimate not only the size of the pelvis, but the size of the fetal head, which can best be obtained by the Miller method In a case of this kind we should not allow the gestation to be protracted, and much will be gained by timely interference

Dr William R. Nicholson—It strikes me that the induction of premature labor is one of our most useful obstetrical procedures, since the smaller grades of pelvic deformity are the common ones met with It seems to me that to allow a woman with a contracted pelvis to go into labor with her first child, to determine whether she can give birth to that child spontaneously is in certain cases a pretty dangerous method to follow, unless the patient be of the best class of society, since in certain grades of practice it is not possible to do cesarean section in private houses, and it strikes me that a method which offers an alternative in the largest number of cases, is a very valuable thing to have in one's possession I think Dr Boyd has stated all the possible objections The only thing that occurred to me in listening to him was that a man who was unfit to put in a bougie so far as sepsis was concerned, was unfit to do a cesarean section While I have not induced labor 100 times, I have never seen the slightest difficulty in regard to the rupture of the membranes, and have never had a case which has shown temperature after the bougie was in place, unless the induction was prolonged and the membranes ruptured

Dr. R. C Norris—We talk about the difficulty of estimating the duration of pregnancy I would like to ask Dr Boyd when he predicts for his patients the probable date of confinement how many times his patients go three or four weeks over that time We do miss it once in a while, but in my hospital and private practice I find quite accurate estimates are made When the estimates have been inaccurate I have explained the error in two ways either the woman herself has made a mistake in her recollection of her last period and of the date of quickening, or she was that type of woman who conceives just before her first missed period rather than just after her last period The estimation of the duration of pregnancy is not difficult when we have a reliable history It is usually in the lower classes that the women forget or disregard the date of their last sickness, and in these cases I admit it is often difficult to determine the duration of pregnancy solely by fetometry You can not do so as accurately as by the history of menstruation and quickening All these facts should harmonize the history of menstruation and of quickening, and the estimated size of the child, and height of fundus I have known the advocates of hasty cesarean section to make the same error in calculation and to deliver six pound babies that have to be put in incubators The plea of my paper is emphasized by Dr Longaker when he speaks of confining our discussion to minor degrees of pelvic narrowing The period of time required for the termination of an induced labor has varied from 6½ to 64 hours The rubber bag is of the greatest value The bougies used alone often will not be efficient I remember Dr Parvin on one occasion putting in a series of bougies which remained for a week or more without bringing on pains In cases of that kind, the rubber bag is essential, and in my cases I accomplished the result in an average of 29 hours, and without danger of sepsis Premature rupture of the membranes when passing the bougie carries with it a certain amount of danger Partial separation of the placenta I have noticed several times, but never with an ill effect on mother or child The danger of infection is a matter of individual equation, and depends on one's aseptic technic The test of labor is justifiable in most degrees of pelvic deformity, and I do not see any disadvantage if the labor is brought on two to three weeks before time You have a smaller baby's head, and if the test shows that the mother is going to fail, you are in a better position to do version or use the forceps with a baby two weeks under its time than with a baby ten days or two weeks over its time I have read nothing in literature, nor heard remarks from men doing frequently the cesarean section for the same grade of cases that would make me change my position, and my own records carefully studied have convinced me more than ever that many cesarean sections can be safely avoided by skilled induction of labor

---

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer]

Muscular Cramps

Revue Medico Pharmaceutique suggests the following formula

R	Vini opii		
	Chloroformi		
	Olei hyocyami, āā	, ℥i	30

M Sig Apply locally with friction If relief is not soon experienced, sodium bromid should be administered internally

Syphilis

In *Lyon Medicale* Molle gives the following prescription of Simonet for secondary manifestations

℞	Hydrarg chloridi corrosivi			
	Sodii chloridi, āā	, gr xxx	2	
	Aquæ dest	m xc	6	
	Pulv gluten	℥ss	15	
	Ext opii	gr xxss	1	50
	Glycerini	m xlv	3	

M Ft pil No cc Sig Two pills three times daily

INFANTILE SYPHILIS

Mercurial frictions, according to *Journal des Praticiens*, are well borne by children The Neapolitan ointment is made as follows

℞	Metallic mercury	500 parts
	Benzoinated lard	460 parts
	White wax	40 parts

M Sig One to five drams to be rubbed into the skin

For an infant the ointment should be rubbed in with a piece of flannel on a different part of the abdomen every morning The ointment should be allowed to remain After a month of such treatment, it should be suspended for a week and then recommenced, and this procedure should be kept up for a year

Local lesions may be treated with

℞	Hydrarg ammoniati	gr xlv	3
	Petrolati	℥i	30

M Sig Use locally

After one year's treatment potassium iodid should be given 1½ grains (10 centigrams) daily for three weeks, ten days intermission, then three more weeks of treatment Every three months, inunction should be resumed for two weeks

Prophylaxis is important, careful choice of wet nurse forbidding of kissing, use of cow vaccine exclusively, with aseptic instruments

In hereditary syphilis, at the end of a year of inunction, half to one teaspoonful may be given daily of Gilbert's syrup

℞	Hydrarg iodidi rubri	gr ivss		30
	Potassii iodidi	℥i	30	
	Aquæ dest	℥i 2/3	50	
	Syrupi cinchonæ	℥xxxi 2/3	920	

M Do not filter Sig One half to one teaspoonful daily

At the end of the second year, 3 grains (20 centigrams) of potassium iodid may be given daily

The liquor of Van Swieten is sometimes substituted

℞ Hydrarg chloridi corrosivi	1 part	
Aquæ dest	900 parts	
Spiritus rectificati	100 parts	

M Dissolve the sublimate in the alcohol, then add the water Sig Ten drops daily for each month of age

The prophylaxis of hereditary syphilis consists of the treatment of the parents, of the syphilitic pregnant woman, discouragement of marriage between syphilitics, and the nursing of the syphilitic child by its mother, never by a nurse

Neuralgia

Revue Medico Pharmaceutique recommends the following formula as valuable in neuralgia

℞ Quinin valerianatis	gr iss	10
Extracti hyoscyami	gr 3/10	02
Extracti cinchonæ	gr ¾	05

M Ft pil No i Sig Take two to four such pills daily

Eye Bruises (Black Eye)

Merck's Archives recommends the following

℞ Acidi acetici dil	℥v	150
Tincturæ arnicæ		
Ammon chloridi, āā	℥i	30
Aquæ dest ,	℥v	150

M Ft lotio Sig Apply locally

Cystitis

The *Critical Review* attributes the following prescription to Keyes, who recommends it as of value in the treatment of acute cystitis

℞ Liq potassæ	ʒiv	16
Ext hyoscyami fl	ʒvi	25
Syrupi aurantii cort	℥iii	90
Aquæ cinnamomi q s ad	℥vi	180

M Sig Teaspoonful in water three times a day

Pepper recommends the following

℞ Potassii bromidi		
Sodii bromidi, āā	ʒii	8
Ext belladonnæ	gr iv	25
Ext buchu	ʒi	4
Syrupi sarsap comp q s ad	℥iv	120

M Ft sol Sig Tablespoonful three times a day after meals

Diet in Diseases of the Liver

Linnosier (*Bull et Mem de la Societe de Therapeutique*, February, 1904) says that it is necessary to exercise care in regard to quantity as well as quality of diet in the treatment of liver diseases Meats are to be more or less completely excluded, according to the severity of the disease Lean ham and fresh fish are the most suitable meats Milk is an excellent article of diet, there is no necessity of excluding the fat from the milk, as it is commonly advised, because the fat, on account of its emulsifying properties, is in many cases well tolerated Fresh vegetables (peas, beans, salads, etc) are to be recommended in cases where digestion is as good as normal Turnips and cabbage, etc , are not to be permitted Bread and dishes prepared with flour may be given to some extent, foods, however, the ash of which is rich in phosphoric acid, are not to be permitted, as they increase the already existing acid intoxication Potatoes, the ash of which is alkaline, are allowed Ripe fruits are suitable on account of their laxative powers and their contents of vegetable acid salts The latter are changed to carbonates and therefore have a favorable influence on the existing hyperacidity Water is the best drink, alkaline waters when there is hyperacidity Small quantities of coffee may be allowed, but chocolate, on account of being rich in fats and oxalic acid, is to be prohibited

Constipation in Infants

Infants who are being fed exclusively on milk either breast or bottle, which is low in percentage of fat are very likely to suffer from constipation Rotch has noticed that when breast milk contains a low percentage of fat and a high percentage of proteids the stools are feeble and watery Boiling and pasteurizing are very apt to cause constipation In breast fed babies it is best to correct the constipation by proper attention to the mother's diet in order to increase its fat First it is important to secure undisturbed rest for the nurse at night She should be relieved of the care and nursing of the infant during the night and the bottle should be substituted if necessary Fresh air should be obtained in abundance by driving and walking when she is able Thomas of New York considers massage of the breast as one of the most powerful stimulants to the secretion of milk It should be done with great care and gentleness, and every precaution taken against infection A mild antiseptic ointment may be used with the massage, and it should be done two or three times a day for ten minutes at a time The diet should be abundant, with a large amount of milk and meat, especially beef If anemia is present iron should be given If drugs must be used to overcome the difficulty the following are to be recommended

Milk of magnesia	ʒss ʒi	2 4
Or		
Olive oil	ʒi	4
Or		
Sodii phosphate	gr ii	12

Other drugs recommended, but of less value than the above are

Calcined magnesia	gr viii x	50 65
Or		
Aromatic fl ext cascara sagrada	m v xxx	30 2
Or		
Pulv glycyrrhizæ comp	gr x xv	65 1

When only local stimulation of the rectum for defecation is required glycerin, gluten or soap suppositories may be used Enematas of soapsuds and water, or equal parts of water and glycerin are very efficacious to effect temporary relief Large injections of fluid (more than 2 to 4 ounces should be avoided) , they may produce overdistention and paresis In bottle fed infants the first attention should be given to the proper modification of the milk so that the correct percentage of fat obtains The other treatment as outlined above may likewise be used in these cases After six months orange juice may be added to the diet and a little later the juice of stewed prunes Massage of the abdomen in certain cases of obstinate constipation has been a most successful treatment

Work as a Therapeutic Measure

This is the subject of an editorial in the *Boston Medical and Surg Jour* 'Among the many rational therapeutic measures which have been advocated of late years, small attention has been paid to the efficacy of work" Rest, exercise, massage, electricity, hydrotherapy, etc , have been used with much success and enthusiasm by many, both within and without the profession The so called "rest treatment" introduced by Dr Weir Mitchell has been demonstrated beyond doubt to be most successful in appropriate cases It has undoubtedly many times been misused and indiscriminately used and consequently has given its best results in the hands of its founder "In view, however, of all the time and attention which has been given to treatment by so called rational methods, it is somewhat extraordinary that no systematic attempt has been made to systematize a method of treatment which shall have work, either physical or mental, as its fundamental principle Of course physicians are continually advising physical exercise and physical labor, but with the possible exception of Moebius no one has mapped out a work cure in the same systematic fashion as the rest cure " The author considers that invalidism is quite often due to other causes than those for which rest and recreation could work a cure It is a very rare experience to come in contact with a person who is really suffering from overwork The work may be uncongenial, the hours long, and physical strength insufficient to meet the demands It is the author's belief that the lack of suitable employment is rather the source of the various failures which are familiar to every physician If it be true that overwork is rare, and that the moral and physical stimulus which work gives is desirable systematic treatment by work is as rational, as systematic treatment by other means Employment of the mind, as well as the body, is conducive to health, and physicians would accomplish far more definite results if they insisted on the necessity of work with anything like the frequency that they insist on the necessity of rest

Antidiarrhea Mixture

The following formula has been used in certain cases in the King's County (N. Y.) hospitals:

℞	Morphin acetatis	gr. i	.06
	Plumbi acetatis	gr. xii	.75
	Aquæ camphoræ	℥ii	60

M. Sig.: One teaspoonful every three to four hours.

Hemorrhoids

The following formula has found favor in the hospitals of the Department of Charities of New York:

℞	Morphin oleatis	1 part
	Camphoræ	2 parts
	Olei sassafras	4 parts
	Resinæ	8 parts
	Ceratæ flavæ	16 parts
	Adipis benzoated	24 parts

M. Sig.: To be applied on lint.

The foregoing is best compounded by melting the wax, resin, and benzoate lard together by gentle heat, and digesting the camphor in this until it is dissolved. While the mass is cooling and before it solidifies, add the morphin oleate and sassafras oil, and mix thoroughly.

An Inhalant in Respiratory Diseases

℞	Iodin	grs. x-ʒi	.65-4
	Carbon disulph.	℥i	30
	Guaiacol	ʒi	4

M. Sig.: To be used as an inhalation in the various respiratory disorders, including the early tubercular stages, bronchitis, asthma, etc.

Drs. Scovall and Twitty, Columbia, Ala., send the above formula, and say they have been using it in their practice for about seven years, and that the results from its application have been very favorable, so much so that they have come to regard it as a specific in that class of post-grippal coughs which have such a direct tendency toward the tubercular state. The addition of guaiacol is advantageous when not objectionable to the patient. The variable quantity of iodin is due to differences in effects and requirements as regards individual cases. The weaker solution is for catarrh of the upper tract and for nasal inhalation, the stronger in the deeper seated disease and for mouth inhalation. The inhaler must be of glass, its style depending largely on the inspiratory powers of patients. When the lung capacity is good enough the simple tube inhaler with gauze inserted will usually suffice. In other cases the bulb vaporizer will be required.

Medicolegal.

Death from Disease Caused by Wound, Dying Declarations.—The Supreme Court of Alabama holds in Pitt vs. State, that if death resulted immediately from a "bowel trouble," which had been brought on or superinduced by the gunshot wound charged or the amputation of the deceased's leg, rendered necessary by the gunshot wound, the fact that the "bowel trouble" was the cause of death would furnish the accused no protection against a charge of unlawful homicide. It also holds that the fact that the deceased asked that a physician be sent for was not in itself and alone sufficient to affect the admissibility in evidence of his dying declarations, as showing a hope of recovery, it having been shown that he was at the time suffering with severe pain in his bowels, and it being natural that he should want the physician to allay his suffering.

Physicians and Certain Opticians Not Merchants.—The Supreme Court of Iowa says, in City of Waukon vs. Fisk, that a surgeon specialist who treats deformities of the body by the use of straps and braces made according to his measurements would not be classed as a merchant simply because he habitually supplies his patients with the necessary apparatus by orders on the manufacturer, and receives or collects payment therefor. Neither would we so class a physician who receives a commission on prescriptions filled by a pharmacist. Likewise, it holds that a traveling optician who does not carry spectacles or eyeglasses for sale, but examines and tests the eyes of persons applying to him therefor, and writes the description of the glasses required on a "prescription blank," which is mailed to a dealer, in Chicago, who fills the order by grinding and preparing the glasses according to the directions, and sends them direct to the customer, is not a merchant, and can not be subjected to a license tax as one, by a city authorized to define by ordinance who shall be considered transient merchants, to regulate, license and tax their sales. The court says that such an optician's business may not rank professionally with that of a surgeon or physician, but his business bears a close relation to theirs, in that he assumes to diagnose, and, to a certain extent, remedy, a physical defect. His skill and experience in this respect constitute his capital and his "stock in trade," and the fact that he finds his compensation in a profit or commission on the apparatus by which he aids defective sight does not make him a merchant.

Compulsory Vaccination of School Children.—The Supreme Court Commissioners of California say, in French vs. Davidson, that in the case of Abeel vs. Clark, 84 Cal. 226, the title of the "Act to encourage and provide for a general vaccination in the state of California" was shown to be in substantial compliance with the requirements of the constitution, and many authorities were cited illustrating its sufficiency. The uniform operation of the act on a natural class of persons, to wit, school children, was asserted, and its compliance with the constitution in that behalf was declared. That the vaccination act came within the police power of the legislature of the state, and that it was for the public good, was clearly maintained by the opinion. It was also shown that the act in no way impaired any constitutional provision against special legislation. The soundness of that decision has never been questioned so far as the commissioners have been able to ascertain. The case has been frequently cited, and the principle of it approved, both in California and in other states. The legislature, the commissioners go on to say, no doubt was of opinion that the proper place to commence in the attempt to prevent the spread of a contagion was among the young, where they were kept together in considerable numbers in the same room for long hours each day. It needs no argument to show that, when it comes to preventing the spread of contagious diseases, children attending school occupy a natural class by themselves, more liable to contagion, perhaps, than any other class that we can think of. This effort to prevent the spread of contagion in a direction where it might do the most good was for the benefit and protection of all the people, and there is in it no element of class legislation. It in no way interferes with the right of the child to attend school, provided the child complies with its provision. Police regulations generally interfere with the liberty of the citizen in one sense, but it is no valid objection to a police regulation that it prevents a person from doing something that he wants to do, or that he might do if it were not for the regulation. When it has been determined that the act is within the police power of the state, nothing further need be said. The rest is to be left to the discretion of the lawmaking power. It is for that power to say whether vaccination shall be had as to all school children who have not been vaccinated all the time, or whether it shall be resorted to only when smallpox is more than ordinarily prevalent and dangerous. Nor does the fourteenth amendment or any other part of the federal constitution interfere with the power of the state to prescribe regulations to promote the health and general welfare of the people.

Defenses for Charging Insanity of Person Not Insane.—The Supreme Court of California says, in the case of Griswold vs. Griswold, an action by a sister against a brother for charging her with being insane and causing her arrest and imprisonment in the insane ward of the county hospital when she was not insane, that it was incumbent on her to prove both want of probable cause and malice, to recover damages. On the other hand, the brother had the right to prove that he acted in good faith, without malice, and on probable cause, that is, on such facts and information as would induce a reasonably prudent man to believe that his sister was insane. It was not necessary that the statement to and advice of the family physician should have been sufficient to constitute probable cause as a matter of law to make it admissible in evidence He was supposed to be skilled in his profession, and to know more about the mental condition of the sister than any attorney at law could have known If the brother had not consulted the family physician, but had gone to an attorney at law, it would certainly seem that he had much less ground for the prosecution than by pursuing the course he did He was accused of acting maliciously Did it not tend to disprove malice if he went to the family physician and fully and fairly stated the facts? It is the policy of the law to encourage prosecutions when there are facts and circumstances that would induce the belief in the mind of a reasonably cautious man of the guilt of the party accused And so in case a party is insane and dangerous to be at large It would not do to hold honest parties in heavy damages for an error of judgment If so, it would be difficult to get responsible parties to make complaints All that the law requires as a defense to this kind of an action is the existence of such facts and circumstances as would induce the belief in the mind of a reasonably cautious man that the party was insane at the time the charge was made If such facts and circumstances existed, the plaintiff ought not to recover damages Again, the court holds that an instruction was clearly erroneous which told the jury that, it being admitted by the brother in his answer that his sister was not insane at the time he had her arrested, the law presumed that in procuring her arrest he acted without probable cause and maliciously, and the burden of proof was on him to show probable cause and want of malice on his part The court says that the question before the court and jury was not as to the sanity or insanity of the plaintiff at the time of her arrest, but as to whether or not there was probable cause for her arrest, as that term is understood by judges and the legal profession And the burden is always on the plaintiff to show that the suit or proceeding was instituted without probable cause and maliciously Moreover, language which might be construed as holding that malice is legally presumed from want of probable cause should be avoided

1 **The Public School and Tuberculosis**—In discussing the subject of how *may* the public school be helpful in the prevention of tuberculosis, Knopf takes up the duties of the school board with reference to choosing a site for a school and the construction of the school, the duties of the superintendent of a public school in arranging the curriculum so as not to overtax the brain and the nervous system of the children, the duties of the school teacher in carrying out the ideas of the superintendent, and those of the school physician in relation to the prevention of tuberculosis He has compiled a set of rules, a copy of which is given to every child who is urged to read them, to take them home, and to show them to their parents

Do not spit except in a spittoon or a piece of cloth or a handkerchief used for that purpose alone On your return home have the cloth burned by your mother or the handkerchief put in water until ready for the wash
Never spit on a slate floor sidewalk, or playground
Do not put pins in your mouth
Do not put your fingers into your mouth
Do not pick your nose or wipe it on your hand or sleeve.
Do not wet your fingers in your mouth when turning the leaves of books
Do not put pencils into your mouth or wet them with your lips
Do not hold money in your mouth
Do not put anything into your mouth except food and drink
Do not swap apple cores candy chewing gum half eaten food, whistles, bean blowers or anything that is put in the mouth
Peel or wash your fruit before eating it.
Never cough or sneeze in a person s face Turn your face to one side and hold your hand or handkerchief before your mouth
Keep your face and hands and finger nails clean, wash your hands with soap and water before each meal
When you don t feel well have cut yourself or have been hurt by others do not be afraid to report to the teacher

A systematic examination of school children, and the supervision of the sanitary condition of the school buildings, are two things that should receive the most careful attention from the school physician Public school sanatoria for the treatment of tuberculous and scrofulous children are an urgent necessity They will serve as places for the cure of tuberculous children, many of whom, without this, will ultimately develop the more severe type of the disease, and will become burdens either to their parents or to the community at large

10 **Meteorologic Conditions and Pneumonia.**—Anders has made an extensive study of the relation of meteorologic phenomena to pneumonia and concludes that the seasons exert a marked effect on the prevalence of lobar pneumonia, the maximal mortality being observed during the winter and spring months That insular climates probably manifest the greatest rise in pneumonia mortality in winter, while that of continental climates coincides mainly with spring That the mortality of the epidemic form of the disease is, to a less extent, influenced by the seasons, and may occur in the third or fourth quarter of the year That an apparently close relationship exists between periods of low temperature and the death rate from pneumonia That the mortality rises and falls with the barometric pressure, the maximal level being reached during periods of highest pressure and vice versa, that the barometric pressure, however, is governed by the temperature, being inversely as the latter, is to be recollected That the average velocity of the winds and the death rate from this disease would appear to stand to one another in the relation of cause and effect That the coincidence of existing low temperatures, high barometric pressure, the direction and velocity of the winds and maximum mortality from pneumonia, is so uniformly constant as to merit serious consideration and suggest a close and direct relation between their combined influence and the progress of mortality from pneumonia That the mean relative humidity of the atmosphere shows equally decided variability during the periods of abeyance in the prevalence and fatality of the disease with that of the cold or annual pneumonia season. That the major influence exerted by the seasons, however is probably not direct, but indirect, namely, by bringing about that effective element in the causation, concentration, and increased virulence of the specific poison in consequence of closed doors and windows and lack of free ventilation

21. **Intestinal Obstruction Following Appendectomy.**—McWilliams summarizes his paper as follows:

1. The rarity of intestinal obstruction in comparison with the innumerable operations for appendicitis is noteworthy.
2. Obstruction may follow an attack of appendicitis which has not undergone operation. Nine such cases occurred in this series of 86 cases, or 10 per cent.
3. Obstruction may follow the "interval" operation. Eight cases, or 9 per cent, belong to this category.
4. Obstruction is most apt to follow appendicitis with abscess formation. Sixty nine, or 81 per cent, were of this class. Hence the necessity for early operation.
5. Mechanical obstruction may come on within a short time after the appendicitis operation, when the differential diagnosis from that due to peritonitis may present great difficulties. When in doubt, operate, for many patients have undoubtedly died, unoperated on, with an unrecognized mechanical obstruction (with or without peritonitis) where the erroneous diagnosis was made of simple uncomplicated peritonitis.
6. Obstruction may occur years after the original attack or operation (e. g., 10 cases occurred in the second year), when it may come on suddenly in perfect health or preceded by a period with symptoms denoting 'partial' (chronic) occlusion, the right interpretation of which symptoms from a prophylactic standpoint is of the greatest importance.
7. There may be several attacks of true mechanical obstruction. In the above series of 86 cases several attacks occurred in 5, or 8 per cent, of the 57 patients who survived the first operation for obstruction.
8. Of the 86 patients 57, or 66.3 per cent, recovered after operations for obstructions. Twenty nine patients, or 33.7 per cent, died.
9. The small intestine was occluded in all of the 50 cases where it was noted.
10. The cause of the obstruction was given in 53 cases as follows: Constrictions by bands in 28 patients, volvuli in 10, kinkings or angulations in 11, and internal hernias in 4 cases.
11. Gangrenous bowel was encountered in 5 cases necessitating resection, resulting in three recoveries and two deaths.
12. We may expect a much smaller death rate in the future due to the earlier recognition of the symptoms and their more prompt relief by operation. Fecal vomiting should not be waited for.
13. Prophylaxis consists in operating on appendicitis before the formation of pus, the use of as little drainage as possible, and the least possible amount of handling of the intestines at the time of operation.
14. Vigorous abdominal massage with elevation of the hips may avert an impending obstruction. Frequent change in patient's position is likewise recommended.
15. Since the exciting cause is in many cases an attack of acute indigestion, patients should have their diet carefully regulated for from four to six weeks after an attack of appendicitis or after an operation.

23. **Endermol, an Ointment Base.**—This is a combination of stearic acid amide and paraffin hydrocarbons forming an almost white mass of about the consistency of lard, inodorous, of neutral reaction, and fusing at 78 to 80 C. Coblentz says that when exposed to the air and sunlight under adverse conditions, samples of endermol retained their color, consistency and blandness. When applied to the skin by inunction, endermol forms a smooth, soft, unctuous mass, which is readily absorbed. Applications of endermol ointments of iodin and also aconite were followed by the excretion of iodin in the urine after about five hours in the former, and the characteristic dryness of the throat in the latter. There is absolute freedom from any tendency toward rancidity, although as much as 15 per cent. of water may be incorporated. It is pliable, smooth and free from all irritating properties.

Boston Medical and Surgical Journal

26 *Clinical Topography of Lymph Nodes. F. J. Cotton.
27 Surgery on Old Men. Wm. H. Arthur.
28 *Mental Defectives. Bertha C. Downing.
29 Operations on the Stomach with Report of Cases. (Concluded.) John C. Munro.

26. **Clinical Topography of Lymph Nodes.**—Cotton calls attention to the fact that the lymph nodes are frequent sources of infection, and that we neglect such aid in locating the primary foci as may be obtained by applying our knowledge of the topography of lymph channels. We need to know more of the practical anatomy of the lymphatics. Such knowledge will insure the identification and proper treatment of local foci of infection that might otherwise be overlooked and also assist us in understanding the glandular conditions. More exact attention to and some familiarity with the grouping of glands and their drainage areas will set us right in regard to 1. Many so called "scrofulous" neck glands in children, which show up first in the posterior deep and superficial glands. Sometimes they are tuberculous; in nearly all cases, however, they are septic; in all cases they are traceable to primary scalp irritation, usually from pediculi. Remove the pediculi, make small incisions for the pus, and the great majority will get well promptly without the enucleation now so frequently carried out for these as well as the really tuberculous cases. 2. Buboes of unknown origin, non venereal, lying low in the groin, due to a septic focus on the foot or leg, which is often overlooked by patient and physician. 3. True inguinal buboes, associated with gonorrhea, but almost never due to it, but secondary to some septic process under the prepuce which should be, but rarely is, found. The writer cites 67 cases in confirmation of his theory.

28. **Mental Defectives.**—Downing makes an earnest plea for the examination of every school child by a competent commission, under state supervision, and if found to be mentally defective should at once become a ward of the state for proper training and care. The fact that feeble mindedness often is inherited, supplies a solid foundation on which to base restrictive and preventive measures. Downing examined 3,000 entrance blanks and found tuberculosis to be the chief factor in the generation of idiocy. The exanthematous diseases furnish a rather high percentage of causation of feeble mindedness. Consumption is a more common hereditary cause than are epilepsy and insanity.

30. **Arteriosclerosis of the Spinal Cord.**—The authors describe a case which they believe is typical of arteriosclerosis of the spinal cord, a condition which, though much less common than cerebral arteriosclerosis, yet is worthy of careful study. The patient, a fireman, 51 years old, complained of the following symptoms in the order of their development: (1) Weakness and easily induced fatigue of the legs, (2) peculiar sensations in the lower extremities, described as "jerky," "numbness," "heavy" and occasionally sharp pain; (3) Progressive incontinence of urine, (4) progressive paraplegia. Aside from the fact that the tendon jerks were absent and that the Babinski phenomenon was present, the objective symptoms were those usually found in chronic transverse lesions of the cord, namely, slight disorder of sensibility, paraplegia, and trophic manifestations. The cause of death apparently was cardiac weakness. An autopsy was permitted, and the brain and cord were removed. The naked eye appearance of both was normal. In dividing the cord into different segments several areas in the lower dorsal segments were seen to contain small hemorrhages in the posterior horns on the right side and a similar condition in the left anterior horn. Microscopically, the arteries and veins everywhere throughout the cord and brain were sclerotic. Spinal arteriosclerosis is a condition that permits of being diagnosticated with considerable readiness, especially if there are symptoms, subjective or objective, pointing to generalized arterial sclerosis.

31. **The X-Ray in Tuberculosis.**—Tousey is of the opinion that judicious application of the *x* ray or of the ultra violet ray and high frequency currents is indicated in every case of tuberculosis, especially tuberculosis of the larynx. One case in point is reported in which the treatment was remarkably successful. The expectoration ceased inside of three weeks, there was great improvement in the voice, marked gain in strength, normal temperature, and a gain in body weight of about two pounds. The local condition also has improved, the area of infiltration has diminished, the abrasions have healed with a whitish appearance which may be due to cicatricial tissue. The treatment consisted, first, in exposure to the *x* ray once every four or five days, exposure to the Cooper Hewitt light and application of high frequency currents once in each interval between the *x* ray applications. In applying the

x ray he used an eight inch Wappler coil, run by the street current (110 volts direct current), using a liquid interrupter This consists of a beaker of tough porcelain with three or four pinholes near the bottom, this is set in a large jar full of dilute sulphuric acid, and a lead plate connected with one wire dips into the acid outside, while a lead ring from the other wire dips into the acid outside of the beaker When the current is turned on electrolysis takes place in the dilute acid through which the current has to pass, and the resulting bubbles of hydrogen and oxygen gas block up the pinholes and interrupt the current The current ceasing, the bubbles of gas escape and the current recommences A special application was made to the larynx by means of a specially constructed *x* ray tube. The tube is held close to the outside of the larynx, and directs the rays through the exact tissue we wish to influence, and requires no shield of any kind In the treatment of tuberculosis of the prostate and bladder, the author allowed the light from an ordinary *x* ray tube to shine obliquely downward through the lower portion of the abdomen and also, occasionally, through the perineum Each application lasts about five minutes Alternating with this perineal application a special *x* ray tube was introduced into the rectum The other portion of the treatment consists in the application of high frequency currents over the lower portion of the abdomen, and in the rectum on occasions when the intra rectal *x* ray tube is not used. For the intra rectal applications of high frequency currents a special vacuum electrode is employed in which the tube is insulated except for its distal two or three inches by a separate external cylinder of glass In this way all the effect reaches the interior of the rectum The application lasts five minutes His results have been excellent

42 **Borated Food and Nephritis**—Harrington says that the two most commonly employed chemical preservatives of food are borax and boric acid They are used so extensively that persons of all ages are likely to receive frequent, if not daily, doses of one or of the other or of both They are added to milk, butter, oleomargarin, some forms of cheese they are almost always present in opened clams and oysters, they are applied externally to fresh meats to prevent sliminess and to freshen salted fish They are important constituents of the brine in which meats are pickled and corned Their solutions are injected into ham and other pork products, and they are found in almost every known make of sausages, to prevent the sausage contents from contracting and thus causing the casing to appear loose and wrinkled Moreover, they preserve the natural color Once established in the tissues borax can not be soaked out not even boiled out The author points out that many cases of slight kidney disturbance may be due to the continued ingestion of the boron compound Experiments have been performed from time to time with a view to establishing the relationship between these food preservatives and kidney lesions Unfortunately, most of these experiments extended over too short a period of time to lend any weight to the results obtained Harrington submits the details and results of a feeding experiment which he conducted for a period of nineteen weeks Twelve healthy male cats were selected and kept under precisely the same conditions in separate cages All were fed on the same food with this difference One received no preservative, six received borax from 48 to 112 grams in daily doses extending over a period of from 50 to 133 days The average minimum dose was 544, the average maximum dose 857, the remaining five cats received another preservative which proved to be innocuous Of the dozen animals under observation but three showed any sign of illness and they were of the borax group One died at the end of the sixth week the other two were sick occasionally, but during the last weeks of the experiment appeared to be normally active Each cat was weighed at the end of each week, all showed occasional losses, but with the exception of the one that died there was a net gain ranging from 230 to 900 grams When the animals were killed a careful autopsy was made and all the tissues were examined microscopically The control animal showed no lesions whatever The animals that were fed on borated food all showed kidney lesions and changes in the liver The five cats that were given another preservative showed no marked changes in the kidneys or elsewhere The kidney lesions of the cats fed on borated food were of the same general character, but differing in intensity They consisted in degeneration of the tubular epithelium, most marked in the convoluted tubes The normal fat vacuolation was greatly increased and there was focal swelling and disintegration of epithelial cells, with fragmentation of nuclei The lumen of many of the collecting tubes contained irregular granular masses representing cell fragments Some tubules were completely stripped of epithelium In one kidney the change was confined entirely to degeneration of an intense character, with hyaline casts in the small tubes In other cases the degeneration was not so intense, but was accompanied by foci of cellular infiltration, most marked at the cortex, and also around single glomeruli Where this was most intense the tubules were entirely destroyed The lesions were analogous to those found in subacute and chronic nephritis in man, although they do not conform to any type

43 **Inhalation of Gasoline Vapors.**—Some years ago Sollmann began an investigation of the effects of gasoline vapors with a view to finding a cheap anesthetic for laboratory work The results were not practical, hence their publication was delayed The renewed interest in the subject aroused by the employment of petroleum ether in Schleich's inhalation mixture is the reason for publishing at this time a brief summary of his work In most of his experiments he employed commercial gasoline and in the others he used a pure sample of petroleum ether The effects were identical The experiments were confined to dogs and frogs and the following mixtures were used Pure gasoline, gasoline 1 to alcohol 8, gasoline 1 to alcohol 5 gasoline 1 to alcohol 3, pure gasoline preceded by an injection of half a dose of morphin He summarizes his results as follows Gasoline (or petroleum ether) when inhaled has a comparatively slight anesthetic action However, the anesthesia is very dangerous, since gasoline also causes convulsions weakening of the heart, vasomotor depression, paralysis of respiration and irritation of the kidneys The effects are produced very promptly, but recovery under artificial respiration is also prompt

46 **Pyopericarditis.**—The medical aspects of pyopericarditis are described in detail by Scott who also reports four cases LeConte presents the surgical side, and the authors summarize their paper as follows 1 Purulent pericarditis is quite frequently overlooked in lobar pneumonia and in other pyemic states 2 Its presence modifies pre existing disease to a considerable extent 3 In diseases with high temperature the presence of purulent pericarditis depresses the fever range and increases the respiratory and pulse rate without sufficient clinical evidence of trouble elsewhere than in the pericardium 4 It is yet to be proved that the heart in case effusion is

medicine The evacuants and proper feeding are valuable In the third class of cases the most important feature in the treatment in addition to the ordinary treatment of delirium tremens is stimulation These patients must have stimulation early, and the stimulant par excellence is alcohol Digitalis is used when the pulse is weak, feeble and rapid, and the delirium undergoes a corresponding change—that is, becomes asthenic in character Collins believes that sedatives are used too often and too indiscriminately The greatest care should be taken in the application of mechanical restraint lest the encroachment on respiratory mechanism lead to supplemental complication and jeopardize the life of the patient There will rarely be any necessity for mechanical restraint in any case of delirium tremens if the indications above outlined are followed

4 School Diphtheria in the Metropolis C J Thomas
5 *A Plea for Oral Hygiene K W Goadby
6 *The Segregation of Tuberculous Patients Among Factory Workers C W J Brasher

5 **Oral Hygiene**—Goadby believes that the far reaching and widespread effects of the ravages of oral sepsis as a factor in disease are by no means always attributed to their proper cause Among children, in particular, chronic inflammation of the mouth should be regarded with the utmost suspicion as a mode of hibernation of infectious diseases Among children we find impaired nutrition, and with it impaired growth, with this, again badly developed maxillæ, thus completing the vicious circle Among diseases associated with oral sepsis are the following 1 Chronic infection of the lymphatic glands of the neck by septic mouth lesions 2 Anemia and lowering of the resistance of the gastric mucous membrane by the swallowing of staphylococci which are present constantly in suppurating gums 3 Impaired nutrition due to inefficient mastication owing to carious teeth The persons who require treatment fall into three classes 1 Children in schools and children before they reach the school age 2 Young adults, such as the domestic servant, shop assistants, etc, who, generally, are unable to pay for services 3 The general mass of the working class population many of whom can afford small payments For children under the school age efficient cleansing of

the teeth is all that is required In order to take care of the teeth of school children properly the author favors the appointment of dental surgeons, whose work should consist of 1 Periodical inspection once in three months, at least, of the children at the schools 2 The treatment of dental caries and conditions of oral disease at some central place to which the children could be sent. 3 The superintendence of the periodical cleansing of the mouths of all the younger children by an intelligent assistant, under the supervision of the dental surgeon For the cure of the second and third class Goadby suggests the following 1 The appointment of dental clinical assistants, at a salary, by the various dental hospitals 2 That a nominal payment be made by the patients to cover the working expenses 3 Only the treatment of dental caries and of oral sepsis be allowed 4 The clinical assistants should be under the jurisdiction of the hospital staff In this manner oral cleanliness can be given the attention it deserves, and much harm averted

6 **Tuberculous Factory Workers**—Brasher describes the method of procedure at a large factory in Bristol having in view the segregation of tuberculous patients Applicants for work are examined as for life insurance particular attention being paid to the condition of the lungs and heart. Those having very unhealthy tonsils or suffering from adenoids are required to submit to operation before being admitted to the factory The superintendents are instructed to report any evidence of failing health in any employe All girls suffering from phthisis are suspended from work and put on the "sick fund" Until they can be sent to a sanatorium they are treated at home or at the factories, and are instructed as to proper diet, ventilation, rest and other details of the "open air treatment" Patients who have suffered from phthisis are not encouraged to return to the factories after apparent cure, but rather to seek some outdoor employment and are assisted as far as possible to obtain such Patients with tuberculous lymphadenitis or peritonitis are allowed to resume work if cured but no phthisical patient would be allowed to return to work until repeated examinations of the sputum had given uniformly negative results The results obtained have been excellent, such as warrant the institution of similar methods in all factories employing much help

7 **Serum Treatment of Exophthalmic Goiter**—Murray prepared an antitoxic serum to be used in the treatment of exophthalmic goiter by injecting rabbits with from five to ten minims of liquor thyroidei daily for a period of about five weeks After thorough coagulation of the collected blood the serum was decanted into small sterilized glass bottles 0 2 per cent carbolic acid was added, and the glass stoppers were sealed with paraffin Two cases were treated with this serum, the dose varying from 5 to 10 minims, given three times a day Although the condition of both patients improved considerably the subjective symptoms being diminished in severity Murray is inclined to ascribe this improvement to the rest in bed and not to the serum He believes it quite possible that if larger animals were employed—he used rabbits—and larger doses of thyroid extract given, a serum might be obtained which could be used for hypodermic injection in acute cases, or for administration by the mouth in chronic cases, where prolonged treatment would be required

11 **Hemorrhagic Smallpox.**—Fraser calls attention to the variation in the number of cases of hemorrhagic smallpox in different epidemics and presents a clinical note of 36 cases He recognizes three types of hemorrhagic smallpox 1 Characterized by the appearance during the initial stage of the disease of hemorrhagic changes in the skin and visible mucous membranes, resulting in the production of petechiæ and ecchymoses, the patient almost invariably dying before the characteristic smallpox eruption has had time to declare itself 2 Cases in which the hemorrhagic element involves not only the region of the pock but areas free from eruption 3 Cases in which the area of the pock alone is involved A review of Fraser's report brings out one or two prominent points In the first place, the unvaccinated person suffering from smallpox appears to be more liable to this type of the disease than the vaccinated In his cases 3 3 per cent of unvaccinated persons suffered from the hemorrhagic type, as against 3 1 per cent of the vaccinated Only 3 out of his series of 36 cases were under 10 years Out of a total of 1,200 treated at the Dagenham Hospital during the epidemic of 1902—from which Fraser takes his 36 cases of hemorrhagic smallpox—198 persons were under 10, practically all of them being unvaccinated, 1 5 per cent of these suffered from the hemorrhagic variety as against 3 3 per cent of all cases over that age Men were more frequently affected than women, in the proportion of 20 to 16 Fraser directs attention to an interesting fact the voraciousness of the patient's appetite and his ability to retain and utilize nourishment In a few cases gastric derangement with vomiting was prominent, and even in these cases the patients displayed an anxiety for food which they were unable to retain This seemed to be a characteristic of smallpox patients in general, the increased gravity of the hemorrhagic type did not appear to diminish the desire for nutriment

Glasgow Medical Journal

August

15 *Case of Chronic Lymphatic Leukemia John W Findlay
16 Intraperitoneal Hemorrhage and Hematocele Arising from Tubal Abortion or Rupture, with Records of Illustrative Cases G Balfour Marshall

15 **Chronic Lymphatic Leukemia.**—Findlay reports a case of this kind occurring in a man aged 60 who complained of weakness and breathlessness of sixteen years' duration, and of pallor and of enlargement of the lymphatic glands of two years' duration There was a well defined history of syphilis contracted over forty years ago, but until two years ago the symptoms of the present trouble were not very marked, except the weakness and breathlessness The patient first noticed lumps under his chin, which increased steadily in size for two or three weeks, after which they got smaller until they became little larger than haricot beans Next the glands on both sides of the neck swelled then the glands in the left axilla followed by those in the right All these glands first became large and then small and hard Edema of the face and eyelids, feet and legs has existed for about one year There have never been any fainting fits or attacks of giddiness and palpitation The dyspnea became so bad as to confine the patient to the house For several months there was pain and tenderness over the lower half of the sternum The appetite has been good throughout and gastric and intestinal disturbances have been completely absent Repeated blood examinations showed a marked falling off in the number of red cells as low as 1,175,000 and a leucocytosis of 152 500 The increase in the white cells was confined solely to the small lymphocytes which equaled 95 per cent of the total number The polymorphonuclear neutrophiles fell to 2 5 per cent All the other white cells had fallen below the normal percentage The hemoglobin fell to 25 5 per cent All the glands are freely movable under the skin, no very large glandular masses were seen, the glands were all soft though not at all of that softness which suggests fluctuation The tonsils were not enlarged nor was there any excess of lymphoid tissue about the base of the tongue Thyroid is normal Examination of the heart and abdominal organs did not show anything markedly abnormal The case, beyond a doubt, was one of chronic lymphatic leukemia A slight improvement in the general condition of the patient followed the use of Fowler's solution, 15 minims per diem, the red corpuscles and hemoglobin percentage have increased slightly but the leucocytosis has become much worse

20 *Thyroid Grafting in Human Beings H Christiani

20 **Thyroid Grafting**—Christiani continues his study of homo thyroid grafting He made use of three classes of thyroid 1, normal thyroid substance, 2, slightly altered substance, 3, manifestly altered The recipient organisms were normal in one case, apparently normal in the second, and distinctly diseased in the third case By combining these different elements the grafts paved the way to the following eventualities 1, graft of normal thyroid substance in a normal organism, 2, graft of thyroid tissue manifestly altered in a normal organism, 3, graft of thyroid tissue apparently but slightly altered in an apparently normal organism, 4, graft of normal thyroid tissue in an organism clearly diseased, 5, graft of manifestly diseased thyroid tissue in a manifestly diseased organism, and, 6, graft of slightly changed thyroid tissue in a manifestly diseased organism Some of these tissues were removed in from six to fifteen months after their implantation and subjected to microscopic examination, from which the author concludes that thyroid grafts are possible in man, and that by this means we can obtain permanent neo thyroid glands The results from an anatomic point of view are excellent, provided normal gland be employed They are positive even when moderately changed gland substance is employed, as in cases of slight goitrous degeneration They are negative, on the other hand when an obviously diseased gland is used Further observation will be required to establish within what limits goitrous tissue may be employed with this object in view From a clinical point of view it may be concluded that the preventive thyroid graft that is to say, a graft made in cases where after too radical extirpation of the organ, the subject is threatened with cachexia strumipriva may avert the impending manifestations In idiopathic myxedematous hyperthyroidea grafts are equally apt to develop and persist, provided always that the tissues employed have not undergone too marked changes Since experiments on animals show that the thyroid organ, when it persists with its normal histologic characters is perfectly capable of fulfilling the function, there is no obvious reason to question the probability of a similar result when it persists in man With the object of avoiding the immediate transplantation of the organ from the donor to the recipient Christiani investigated the preservation of thyroid tissue in various liquids and, so far as they go, these researches tend to show that this preservation at any rate in respect to the thyroid of the rat and the rabbit is possible in artificial serum and in the blood serum of certain animals, but only for a comparatively short period of time (rather under an hour instead of ten seconds in the air) The author is carrying on another set of experiments having in view a simplification of the implantation of the thyroid tissue Thyroid tissue, reduced into very small fragments by the aid of a sharp knife and with every precaution to avoid crushing, which would destroy its vitality, may be emulsified in the preservative liquid and injected into the selected organism through a trochar or large hollow needle These experiments, which are still in progress, have not as yet given results sufficiently conclusive to warrant the formation of definite conclusions Thyroid grafting probably never will take the place of thyroid medication Not only does the latter method of treatment remain indicated in cases where grafting is impracticable but it may be required as a preliminary step to grafting in order to prepare the soil in the presence of grave disturbances of nutrition and, indirectly, to assist in the development of the transplanted thyroid tissue by avoiding the risks inherent to too early and exaggerated functional demands

26 *Leucocyte Curve in Surgical Affections C Julliard (Geneva) —De la valeur clinique de la courbe leucocytaire dans les maladies chirurgicales et en particulier dans l'appendicite Etat de la question (Commenced in No 5)

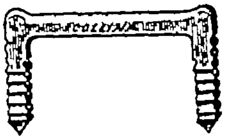
21 **Consolidation of Mobilized Fractures**—The extensive experimental research described demonstrates that daily displacement of the fractured stumps does not prevent consolidation It may be retarded and the callus may be unduly large and misshapen, but the consolidation is very firm The mobilization was much more vigorous than in therapeutic massage and mobilization When a pseudarthrosis forms it is due more frequently than generally supposed to interposition of a fragment of muscle In other cases it is due to the *chevauchement* of the fractured bones A rarefying osteitis may be incriminated in certain cases, and in others a fatty rarefaction of the bone Syphilis is the only general cause known to date, but certain local causes may co operate, among them the interposition of a scrap of bone, effusion of blood or suppuration

22 **Osteomata of the Intestine**—Quénu had occasion to operate on a patient exhibiting symptoms of constriction of the small intestine The stricture was caused by patches of bone formation, the only case on record, to his knowledge of such ossification, neoplasia and consequent stricture formation He gives eight views of the resected portion of the intestine and cites the experience of veterinarians with osteomata in the intestines of horses An osteoma may exist without any other alteration in the intestinal walls In the case described the first clinical sign of its presence was colic pains, very severe Colics from this cause may terminate in rupture of the intestine The osteoma may be associated probably secondarily with a vegetating adenoma of the intestinal mucosa and form a tumor entailing obstruction of the gut The osteoma is also liable to induce ulcerative lesions in the intestinal mucosa (with or without a true neoplasm according to the interpretation placed on the specimens illustrated) entailing in time a tight cicatricial stricture of the small intestine

23 **Perforation of Ulcers in the Lesser Curvature**—Villard and Pinatelle remark that in the surgical treatment of perforated gastric ulcer too little attention has been paid hitherto to the site of the ulcer as an indication for the mode of intervention In 2 cases they found it impossible to expose and suture the perforation on account of its location high up on the lesser curvature They proceeded therefore, to wall off the perforation by throwing up a barrier below This was accomplished by suturing the anterior aspect of the stomach at the middle to the anterior wall of the abdomen This formed two separate pockets The upper pocket included the perforation and the focus of perigastritis It was drained The lower pocket corresponded to the large abdominal cavity In the 350 cases of perforation of a gastric ulcer on record 115 are mentioned as being on the lesser curvature or cardia, that is on the upper and less movable part of the stomach Perforation occurs in only about one third of these "high" ulcers This comparative infrequency of perforation is due to the high protected site, its immovability and frequent existence of adhesions These adhesions limit the peritoneal infection and impress certain characteristics on it, peculiar to the region when it does occur Clinically the persistence of vomiting is a constant sign, antecedents of an ulcer are found more frequently, and the symptoms assume a subacute course or recur in successive exacerbations These clinical findings suggest that it may be better to operate in a preventive sense whenever a patch of perigastritis develops rapidly accompanied by indications of a reaction on the part of the peritoneum The intervention should be the walling off of the patch with gauze supplemented by gastroenterostomy After perforation has occurred a laparotomy should be done at once and the per

foration be sutured, if possible If not, owing to peripheral adhesions or friability of the edges of the perforation, the intervention may have to be restricted to walling off the perforation The protecting adhesions should always be respected In case of extreme friability or extent of the lesion, sutures may be applied at a distance or the perforation may be sutured to the skin or to the omentum, or all three methods may be combined, walling off the site with gauze The bibliography to the end of 1902 is reviewed

24 **Clamp Fixation of Recent, Uncomplicated Fractures**—Dujarier describes 4 cases with a number of illustrations, in which the usual measures for treatment of a recent fracture proved ineffectual Radioscopy showed malposition of the parts, and there was pain and ulceration was feared Under these circumstances an incision was made down to the bone and a couple of two metal clamps, like double headed tacks, were driven into the shaft of the bone to hold the stumps in place after reduction The holes were drilled for the clamp to the exact size and depth of the legs of the clamp and it was driven into place with light blows on the alternate legs, using a light steel hammer with a tapering head and a nail set to insure that the blows fell axial to the points of the clamp and without danger of injury to the soft parts The results in the 4 cases showed that when the clamps are driven in a bone covered with thick soft parts, such as the radius or femur, they remain solidly implanted with no tendency to work loose In a superficial bone they are exposed to this tendency In one of his patients the fracture of the tibia consolidated in less than a month, but the patient returned after a certain time with signs of fistula formation over the callus The clamps were removed without anesthesia and there has been no disturbance since A second patient complained of slight discomfort at the point where the tibia had been fractured and the clamps applied They were removed as a prophylactic measure, fearing that they might work loose later They were found so solidly implanted however that some injury was done to the bone in removing them No attempt should be made to remove them until they give signs of being loose In other cases they healed perfectly in place and insured ideal consolidation of the femur and radius, with perfect functional results, after failure of the ordinary measures The indications for their application may be deduced from the results observed in these 4 cases The age, general health occupation, etc should be considered in determining the indications for the use of the clamps or agrafes as the French call them The latest approved model is shown herewith The side toward the bone is flat and the clamp is made extra thick at the bend to straighten this the weakest point



25 **Bacteriology of Appendicitis**—Lanz and Tavel's communication is based on the bacteriologic study and clinical description of 130 cases of appendicitis Their findings indicate that the normal appendix presents the same microbian flora as the large intestine In case of inflammation leucocytes are attracted to the spot with active phagocytosis, with the result that the pathologic appendix was found sterile in 10 per cent. of the cases (mostly examined *à froid*), while the normal appendix was never found sterile

26 **Leucocyte Curve in Surgical Affections.**—Julliard concludes his comprehensive study of this subject and its literature with the statement that the leucocyte curve is a valuable diagnostic aid in appendicitis, peritonitis, and all affections in which there is suppuration not accessible to exploration It is destined to increase in importance in comparison with the ordinary diagnostic measures consecrated by long experience but which sometimes prove indecisive It is certainly as valuable a sign as the temperature, if not more so In many instances in which the temperature was indecisive the leucocyte curve supplied the missing information The few cases which give paradoxical findings according to our present knowledge may possibly be explained some day, and they should not induce us to disregard such a precious symptomatic element as the leucocyte curve It should be determined in every case of appendicitis in which the surgeon is not absolutely sure whether the case is tending toward aggravation or improvement of the infectious process In such dubious cases the leucocyte curve may prove extremely valuable, both for the diagnosis, prognosis and treatment. In non suppurative appendicitis the leucocyte curve approximates the normal (9,000) or ranges between normal and the lower limit of suppuration, that is, between 10,000 and 25,000 There may be considerable rise at first, but it is briefly transient Suppuration sends the curve above 25,000 for two or three days, and purulent peritonitis causes it to remain high unless the resisting powers are enfeebled When the leucocyte curve remains above 25 000 it indicates suppuration, and this testimony should be given the predominance over that of other, possibly conflicting symptoms The leucocyte curve enables a suppurative appendicitis to be differentiated from typhoid fever, from a non inflammatory tumor of the cecum or fecal stasis therein In the first case it is high in the others it persists normal The absence of a high leucocyte curve, however does not preclude the existence of suppuration, as, in exceptional cases there may be suppuration without hyperleucocytosis Julliard reviews the leucocyte findings in a number of other surgical affections Perirenal abscesses cause a leucocytosis of 12 000 to 25 000, and may thus be differentiated from a cold abscess or tuberculous process Abscesses in the liver send the leucocyte curve higher than any other purulent collection in the organism The leucocytes may number 45 000 to 90 000 In peritonitis a leucocytosis over 25,000 for two or three days is presumptive evidence of pus formation In septicemia the general infection sends the leucocytes up to 37,000 or even 57,800 in some cases and the curve is a valuable means of information in regard to the evolution of the infectious process and the resistance offered by the organism One case of septic meningitis has been reported in which the leucocytes numbered 20 000, while in a tuberculous meningitis they numbered merely 6 000 to 8 000 although the temperature was high Abscesses at the periphery cause much less leucocytosis than deep seated abscess formation In erysipelas the leucocyte findings are frequently absolutely opposite to the temperature findings The leucocytosis increases with the progress of the affection Wassermann observed one case in which the leucocytes increased from 9 600 to 30 500 without any rise in temperature, although terminating fatally The leucocyte findings seem to be contradictory in case of malignant disease, although extensive ulceration is generally accompanied by an increase Another point generally admitted is that the leucocyte curve rises when there is generalization of a primary neoplasm When the metastasis occurs in the bone marrow, myelocytes are usually encountered in the blood In case of ulcer and cancer of the stomach the leucocytosis of digestion may afford diagnostic information In case of cancer there is no leucocytosis of digestion, while it can be noticed in case of round ulcer The leucocytosis of digestion should always be examined before surgical intervention on the stomach in order to determine the condition of the mucosa and the possibility of its functioning Hence the normal condition of the blood in case of a duly diagnosed cancer of the stomach may impel to early intervention. There does not seem to be any parallel between the leucocytosis and the temperature They are not symptoms which can be substituted one for the other, but, on the contrary, they complete and throw light on each other Their nature and final causes are not necessarily identical The leucocyte curve varies more sensitively than the temperature curve The fluctuations of the morbid process are frequently reflected in the leucocyte curve long before they are manifest in the temperature

36 *History of Medicine and Hippocrates M Roth Geschichte der Medizin und H

27 **Cause of Colic**—Wilms ascribes the pains to the pulling and stretching of the distended biliary passages at their points of fixation This pulls on the sensory nerves there, and is the cause of gallstone colic pains When the gall bladder is normal it is more flexible and is able to pull harder than when it has become hard and thick This causes more violent pains, and it may be accepted as an axiom that the nearer to normal the condition of the gall bladder walls, the severer the colic In estinal colic is due to the same cause, traction on the sustaining mesentery The contraction of the intestinal wall tends to straighten out the gut, and the resistance to this straightening out offered by the mesentery is the cause of the colic in this case The conditions are similar in renal colic Occlusion of the ureter causes stagnation of urine with dilatation of the pelvis of the kidney and consequent pulling and stretching of the capsule There do not seem to be any sensory nerves in the mucosa of the ureter

28 **Temperature of Diseased Joints**—Kothe has devised a means of taking the temperature over large areas of the body It shows that when there is a disturbance in the circulation within the circulation in the skin over the part also varies from normal to correspond The application of dry hot air raises the local temperature sometimes as much as 8 degrees centigrade Alcohol compresses likewise raise the temperature of the part, but constriction inducing passive hyperemia gradually reduces it

29 **Action of Radium on Animal Tissue**—Heineke's studies have demonstrated that the action of radium rays is approximately the same as that of the Roentgen rays Lymphoid tissue is affected by them through the skin in the same way, but not to the same extent as with the Roentgen rays, unless the radium is brought into close contact, when a brief exposure will induce astonishingly extensive changes in the lymphoid tissue, apparent in a few hours

31 **A Giant Ovarian Cystoma**—Zacharias tabulates 14 of these giant tumors from the literature, including Barlow's case, in which the total weight of the tumor was 135 kilograms, more than 270 pounds He describes a case personally observed in which the distance between the xiphoid process and the symphysis was 110 cm and the circumference of the abdomen 187 cm, over two yards The patient was a small, thin woman but she weighed 264 pounds before evacuation of the cyst and 125 pounds afterward The weight of the fluid evacuated must thus have been about 139 pounds An expl
laparotomy is advisable when an operation is contemp
order to discover a point for the incision where there
adhesions If extirpation is found impossible, repeate
ture is the next resource, but the fluid reaccumulat
stantly in most cases and the intervals have to be made
and shorter It is possible by this means to keep the p
for years in comparative health Ford thus tapped a cy
forty nine times in five years, withdrawing 2,786 pints
ner reports 299 punctures during eight years in one
withdrawing 9 867 pounds of fluid contents

32 **"Steeple Skull" and O** **erve Atrophy**—Velhagen
had occasion to observe hich the skull tapered u
ward, causing the orbit ally shallow, and induc
ing atrophy of the optic izes that this atrophy
may be due partially to e growth in these
parts, and partially to the attains its prin

cipal growth in the period terminating with the seventh year and that a large number of ossifying centers are grouped at the small end of the orbit funnel His patients were 6, 17 and 23 years old, and the eyeballs protruded to a marked extent in each case They applied for relief from the typical symptoms of choked disc Friedenwald found 12 of these "steeple skulls" among 19 cases of visual disturbances accompanying skull deformities In the cases described the symptoms of choked disc became suddenly aggravated and, as suddenly, took an unexpected turn for the better The visual disturbances may subside completely if the cranial deformity is not very pronounced The bone growth in the part is liable to become so excessive that the "physiologic congestion" of normal growth becomes so intense that exudation results, with consecutive ocular disturbances They subside as the exudate is reabsorbed

36 **History of Medicine and Hippocrates.**—Roth remarks that the question whether Hippocrates or several authors wrote the great work which we call by his name can be decided only by the discovery of works preceding or contemporaneous with him None is known to date It is the most ancient and the only monument of Grecian medicine, and its contradictions and problems can be solved only by study of its pages by some physician familiar with the history of medicine Professional philologists or historians are not required for the task Roth sketches the influence of Hippocrates writings on the history of medicine

mercurial treatment restored the other children to health The heads were all within normal limits, merely rather large, a rapid increase in size having been noted Attacks of screaming and restlessness in early infancy were retrospectively regarded as further evidence of hydrocephalus The case emphasizes the little dependence that can be placed on parents' statements—both scouting the idea of a possible syphilitic origin for the symptoms observed in the first fatal case in the family Galatti advocates immediate mercurial treatment in every case of hydrocephalus of uncertain origin The Neapolitan school treats every case of hydrocephalus with inunctions and the successful results observed are probably due to the fact that so large a proportion are of syphilitic origin

39 **Cystadenoma Papillare**—Wienert reports and illustrates what he believes is a hitherto undescribed tumor a papillary cystadenoma originating in the outlets of the glands in the mucosa of the cheek, with cystic degeneration

41 **Pseudo Hermaphroditism**—Swoboda remarks that male pseudo hermaphroditism is of much more frequent occurrence than the female, and yet, in doubtful cases physicians generally advise that the child should be brought up as a girl He protests against this practice, thinking that the arguments are all in favor of bringing such children up as boys, if the parents refuse their consent to a diagnostic operation, or one proves indecisive. He urges legislation to recognize, besides males and females, persons of an 'indeterminate sex" There used to be a law in Prussia allowing persons belonging to this category to choose for themselves, on reaching their majority the sex to which they should nominally belong This law has been repealed, but he thinks it is better than the present law according to which such a person runs the risk of being referred to one sex or the other in turn by different physicians who may examine him in succession

42 **Secondary Infection in Tuberculosis**—Sorgo states that 10 febrile tuberculous subjects were examined for the supposed secondary infection In 9, pure cultures of the tubercle bacilli were obtained, and in only 1 did the findings indicate mixed infection

43 **Mushroom Poisoning**—Hockauf writes from considerable personal experience and acquaintance, presenting an extensive study of mushroom poisoning as observed in Austria

47 **Experimental Cirrhosis of the Liver**—Joannovics was able to induce lesions, similar to those in man by administering to guinea pigs ammonium carbaminate and carbonate by the mouth, by inhalation of alcohol, repeated subcutaneous injections of chloroform, and by the action of poisons like toluylendiamin which destroy the red corpuscles and indirectly induce icterus and lesions in the liver tissue

49 **Super-Infection and Primary Lesion.**—Detre Deutsch is chief of the Jenner Pasteur Institute at Budapest, and has had fine opportunities for the research described It was undertaken to study the question of super infection in syphilis We know that a syphilitic subject can not acquire the primary bubo again This has been assumed to mean that he was immune to reinfection, but the results of the research described show the matter in another light They demonstrate that the initial symptoms induced by a virus in an already infected subject may differ widely from the initial symptoms observed in the primary infection The presence or absence of the initial symptoms is, therefore, no criterion as to the success or failure of a superposed inoculation The altered biochemistry of the organism may cause the primary symptom complex to vary- from the standard type as effectually as in case of acquired immunity The animal organism may have acquired a super infection notwithstanding that the typical initial symptoms of a new infection are entirely absent The research was conducted with tuberculosis on guinea pigs—as many of the conditions approximate those observed in human syphilis

50 **Struma and Tetany**—Jacobi has observed coincident struma and tetany in a mother and 2 children in a working family The children were 10 and 15 years old when the tetany developed In a fourth case the tetany developed and recurred only during pregnancies the patient exhibiting constantly a mild form of exophthalmic goiter This case confirms the assumption of a connection between the thyroid gland and the tetany

52 **Remote Results After Extensive Uterine Cancer Operations.**—It is now four years since Wertheim proclaimed the necessity for more radical extirpation in cases of cancer of the uterus He now announces from his six years' experience that the remote results are incomparably better since he has extended the operation Out of 11 cases, representing an operability of 29 2 per cent, 9 are free from recurrence after four years Out of 31 cases representing an operability of 45 per cent, 10 are free from recurrence after three years Out of 43 cases representing an operability of 51 per cent 26 are free from recurrence after two years In the cases of recurrence the new growth always originated in the iliac glands He has never found one in the inguinal glands. It is impossible to remove all the glands, and the superiority of his remote results is evidently due to his more thorough extirpation of the cancer itself As soon as he adopted his technic of more extensive operating the proportion of operable cases increased from 29 to 45 and 51 per cent He never operates through the vagina except in case of incipient cancroid of the portio vaginalis He believes in extirpating the glands as completely as possible, if only from the prognostic standpoint Recurrence was noted in less than a third of the cases in which the extirpated glands showed no trace of cancer

53 **Functional Diagnosis of the Kidneys.**—Kapsammer denies that cryoscopy of the urine has any diagnostic value beyond that of a mere hint that something is possibly wrong when the freezing point is much below normal He cites a number of instances from his experience to show how misleading it is liable to be In a case of bilateral pyelonephritis for example, the freezing point of the urine was left, —1 17 C and, right, —1 82 In a healthy subject he found the figures respectively —.40 and —.50 C Such anomalies may be due to polyuria of one kidney and to guard against false deductions, the amount of urine secreted by each kidney during a given period should be determined if possible In another case there was bilateral gonorrheal pyelitis and stones in the right kidney, and yet the freezing point of the blood was —.56 the normal figure, as also in another subject a man with bilateral renal tuberculosis In another patient it was also normal although the operation revealed bilateral pyelitis, the left kidney reduced to a loose sack whose walls were nothing but a layer of kidney parenchyma not more than 1 to 2 mm thick The right kidney was contracted and much inflamed only one-fifth of its substance being capable of functioning The Voelcker Joseph indigo carmine test has established its value for revealing the mouths of the ureters for study of the type of the secretion, and, associated with catheterization is a valuable functional diagnostic measure much superior to the methylene blue test Kapsammer modifies the phloridzin test and has thus applied it in 70 cases Thirty of the patients were operated on and the findings exactly confirmed those of the test in every instance The main point for the diagnosis is the interval before the glycosuria appears He makes a subcutaneous injection of .01 gm phloridzin in an aqueous solution, just boiled, so that it is still warm Sugar appears after twelve to fifteen minutes in normal subjects If it does not appear until after twenty to thirty minutes, the kidney is somewhat impaired, but still able to assume the total function If no sugar appears until after thirty minutes, the conditions forbid nephrectomy In a number of instances this test was the only one that could be relied on as an indication for surgical intervention This was recognized too late for some of the cases—the findings at the operation confirming the results of the test which had not been heeded by the surgeon The greatest benefit from these new functional tests—at the head of which he places simultaneous catheterization of both ureters—is in the possibility of an early diagnosis, and enlargement of the sphere of nephrectomy at the expense of nephrotomy He adds in conclusion that we need not dread any reflex anuria of the second sound kidney. The anuria noted and assumed to be of this nature is in reality due to insufficiency of the second kidn

diseased For the Voelcker Joseph test see page 69, of the last volume

59 **Feces in Cholelithiasis**—The results of 85 examinations of feces are tabulated They indicate that the composition of the feces varies materially from normal in case of stoppage of the flow of bile or a supply of abnormal bile

60 **Thyroid Treatment of Cretins**—Seventy two cases of endemic cretinism improved to a remarkable extent under mild thyroid treatment The majority of the subjects were restored apparently to normal conditions

65 **Three Cured Cases of Meat Poisoning**—Pelzl found high irrigation of the intestines, with *some irritating substance* such as glycerin or magnesium sulphate in the water, the best means to promote the removal of the cause and induce copious stools *Calomel and other purges afforded no relief* Another extremely important measure was the prompt resort to artificial feeding through the stomach tube, which abolished the distressing swallowing movements, liable to induce foreign body pneumonia or death from suffocation The mechanical stimulus from the stomach tube and the moistening of the esophagus improved conditions to such an extent that fluids could be safely ingested in two days A favorable effect was also obtained from pilocarpin which was given throughout the week, 20 drops of a 1 per cent solution by the mouth every morning No indications of collapse were observed with this dosage, but they followed a warm bath The diet was at first milk, with a little wine, but as soon as the paralysis of the swallowing mechanism was overcome, a strengthening diet was taken Moist sausages and other moist meat conserves are much more liable to cause meat poisoning than the dry Pelzl reviews the literature and explains the symptoms of botulism observed in his 3 cases as due to the action of the poison on the nuclear region from the end of the third ventricle to the beginning of the spinal cord in the neck He gives a diagram to sustain this assumption grouping the symptoms in 7 phases, appearing in turn, as 1 mild gastrointestinal disturbances, paresis of the intestines in 1 subject and vomiting and diarrhea in the others, 2 extreme dryness of skin, mouth and conjunctivæ, 3, paralysis of pharynx and esophagus muscles 4, *ditto of ocular muscles* 5, *reflex paralysis of muscles used* in closing the lids, coughing, vomiting, etc 6 general weakness of all the muscles, pallor, emaciation, and 7 paresis of the bladder muscles The gastrointestinal symptoms were in inverse proportion to the intensity of the poisoning The essential symptoms of the botulism did not appear until thirty six hours after partaking of the poisonous meat It was in the form of sausage, and had been well cooked just before being eaten There was nothing to suggest to the sight taste or smell that the sausages were spoiled The ocular disturbances were the first symptoms that brought the three soldiers to the physician, about twelve days after eating the sausages, the three previous phases of the poisoning having been borne without interfering materially with their military duties As will be noted the clinical histories differ in several points from those previously on record

82 *Due anni di profilassi malarica tra gli impiegati della rete ferroviaria dell' agro *cerignolano* (malaria prophylaxis on Italian railway) F Buono

68 *Kernig's Sign in Sciatica—Plessi observed this sign in a* typical form in 2 cases of sciatica, in both instances it vanished with recovery Abadie has stated that he found that this sign persisted in 3 cases *after spinal cocainization had* abolished all feeling in the parts In his cases the slow dropping of the cerebrospinal fluid and its normal composition showed that the meninges were intact Plessi thinks that he probably had not induced complete anesthesia of the parts, and that sensibility was retained in certain fibers, enough to induce this "reaction of defence," the sign called by Kernig's name

71 **Calcium Treatment of Tuberculosis**—Michelazzi restricts this report to his experimental research, not entering on his clinical experiences He commenced to treat experimental tuberculosis with calcium salts in 1902 All the control animals have died, while only 0 died of the 30 rabbits and guinea pigs treated with 2 to 3 gm a day of calcium phosphate, mixed with their food, and supplemented by repeated daily injections of lime water The tubercles in the animals were found more or less calcified or walled off by a fibrous enclosure The rabbits were not only clinically cured, but the pathologic anatomy also demonstrated a cure Some rabbits were kept alive for eight months, and they were apparently in the best of health The results were less evident in the guinea pigs, but still sufficiently promising A characteristic cirrhosis of the liver was manifest in these animals, and inoculation of other guinea pigs from their lesions gave positive results He thinks this difference in the results observed in the rabbits and the guinea pigs may be due to the fact that the former were inoculated with tuberculosis by intravenous injection, the latter by subcutaneous injection into the abdomen The calcium salts are deposited at the points of inflammation and afford a mechanical stimulus which starts and aids the process of repair, with a probable additional antagonistic action on the tubercle bacillus

73 *New Research on Cytotoxins—Sartirana has previously* announced that the injection of defibrinated blood alternating with an emulsion of brain substance (guinea pig), induces the *production of a powerful hemolytic and neurotoxic serum* On the other hand, alternate injections of defibrinated blood and of an extract of suprarenal capsule did not confer any hemolytic power on the serum, and only a slight suprarenal toxic action These observations suggested that the capsule extract and the defibrinated blood annulled each other's action He reports here the results of a number of varying experiments in this line on guinea pigs, rabbits and fowls, using the organs from the first No cytotoxic power was conferred on the serum of rabbits repeatedly injected with an emulsion of guinea pigs' suprarenal capsules Contemporaneous injection of brain substance and blood conferred both cytolytic and hemolytic power on the serum He thinks that this new technic of mixing various emulsions of different organs, combining or alternating them, is liable to solve some of the problems in regard to alexins, etc, as well as those of cytolysis

74 **Radiotherapy of Trachoma**—The 2 cases described were of long standing and rebellious to all the usual measures Six exposures, with a total of 44 minutes in one case and of 47 in the other, caused such marked improvement, both subjectively and objectively, that a cure is confidently anticipated The tube had a spark length of 650 to 700 mm, the distance varied from 30 to 45 cm, the applications were from 4 to 10 minutes at a time, and only one eye was treated, the eyeball protected with a sheet of lead at some of the sittings

77 **Sahli's Test of Pancreas Functioning**—A glutoid capsule, made of gelatin hardened with formaldehyd, is not affected by the organic juices except the pancreatic A capsule of this kind, containing iodoform, is supposed to pass unchanged through the alimentary canal until it encounters the pancreatic juice, when it is rapidly dissolved and the absorbed iodoform can be detected in the saliva and urine Sahli has proposed this technic as a means of *testing pancreas* functioning, but Galli reports from Baccelli's clinic a case of cancer of

the pancreas which renders dubious the results [illegible] of the test There could not have been any pancreatic [illegible] as the organ was entirely destroyed but the capsule [illegible] is effectually [illegible] in health

82 **Prophylaxis of Malaria in Italy** Since the [illegible] employes of a certain railroad have been [illegible] the number of cases of malaria has dropped from 64 in 1900 to [illegible] in 1903 while a control line has had 33 40 33 and 21 [illegible] during the same interval The railroad officials comment [illegible] light on the improvement in the general health and working capacity consequent on the refreshing sleep and well ventilated rooms free from the plague of mosquitoes In the Italian army, quinin prophylaxis has reduced the number of cases of malaria from 101 recurrences and 112 new cases the figures in 1898—to 15 and 87 respectively, in 1903 The total number of persons thus prophylacted in 1903 was 19 021 and only 10 per cent showed symptoms of malaria [illegible]

84 **Tetany in Children**—Peters expatiates on the importance of the information to be derived from two new signs which, in connection with Trousseau's symptom, enable even latent tetany to be differentiated The "jumping jack sign," is particularly valuable This is the jerking induced in the arms and legs when the galvanic current is turned on, the anode on the chest and the cathode on the cervical or lumbar enlargements The other sign—Quincke's lumbar puncture—has direct therapeutic as well as diagnostic value After the spinal canal has been relieved of the excess of cerebrospinal fluid, it is impossible to elicit the jumping jack sign for some time His work is based on examination of 600 children between four months and three years old Latent tetany was discovered in 22, associated with evidences of rachitis in 17, but not dependent on the latter, the coincidence being merely casual, he is convinced Examination of 77 children with a severe form of rachitis revealed latent tetany in only a single one Among the children with latent tetany were a number with excellent digestion, normally nourished, while, on the other hand, no signs of it could be detected in a large number of cases of severe debility and infectious processes All the signs and the tonic character of the spasms indicate a spinal origin for them The jumping jack and the Trousseau signs indicate a localization of the process in the region of the roots, while the latter sign suggests that the process develops on the side toward the dura where ganglia accompany the roots The jumping jack sign on galvanization of the cervical and lumbar enlargements together with the increased amount of cerebrospinal fluid indicates further that other tissues besides the nerve elements participate in the process, the bones, muscles and meninges Hypertension alone, without other signs, has no differential significance, but the Trousseau sign is pathognomonic, or at least, when it is absent, tetany can be diagnosed only when the other signs are pronounced, either the jumping jack or the Chvostek, Erb or Bekhtereff signs or the Frankhoff reaction to the galvanic current in the peripheral nerves and muscles In case of organic affections of the spinal cord or brain, none of these signs is observed, nor in organic affections of the peripheral nerves In one case the jumping jack sign was noted with some rigidity in the muscles of the back of the neck, throwing doubt on the correctness of the diagnosis, and suggesting rather poliomyelitis or dystrophy, with compression of the cord in the cervical region In fact, digital examination through the mouth revealed a cystic abscess on the anterior aspect of the spine, a result of spondylitis of the upper cervical vertebrae In 2 cases of epilepsy the occurrence of the jumping jack symptom, with excessive pressure in the cerebrospinal fluid, suggested the assumption that, besides the cerebral affection, there was also some complication on the part of the spinal cord Some of these signs of tetany were observed in 2 cases of hysteria In 5 out of 9 cases of eclampsia the positive findings of these 3 signs revealed the presence of tetany In respect to "latent tetany," he does not agree with those who regard it as a physiologic property of early childhood (Goltmann's spasmophilia) Latent tetany represents, *per se*, the participation of the spinal cord in the morbid process, but it may develop into the extreme type of eclampsia in which the symptoms seem to be exclusively cerebral Latent and declared tetany should be accepted as a single morbid process, but latent tetany and rachitis are two distinct entities

85 **Raw Meat in Treatment of Tuberculosis.**—Knotte summarizes the reports of this method of treating tuberculosis published by various authors, and then relates his own experience with over 30 patients The first was a man of 30, of a consumptive family, infected with syphilis ten years before, which had required energetic specific treatment, suffering also from neurasthenia and exposed to severe climatic vicissitudes Notwithstanding all these unfavorable circumstances, the patient made marked improvement under the "zomo therapy," according to Héricourt and Richet's directions The other patients were put on the raw meat for longer or shorter periods, and all were objectively improved Eight patients followed the course systematically for from three to six months, about 300 to 350 gm of raw meat being taken as the daily dose His experience confirms the efficacy of zomo therapy as a powerful aid in the treatment of tuberculosis, especially when it is impossible for the patient to seek a more favorable climate His patients all improved both objectively and subjectively, but none was actually cured The liver and kidneys must be watched during this treatment to prevent disturbance in their functions from the raw meat When this is done zomotherapy can be regarded as an efficient builder up, with a certain specific action on the morbid process, the improved nutrition, in turn, having a further specific action on the infection Richet believes that the elements of the meat combine with the cells of the body in such a way that the latter lose their chemical affinity for the tuberculous toxins

89 **Cirrhosis of the Liver Without Ascites**—The interest in the case described lies in the fact that Nature had established a collateral circulation such as is sought by the Talma operation The result is that there has been no ascites during the eight or nine years of the liver affection The enlarged veins of the collateral circulation can be distinctly traced through the skin over and on both sides of the median line from the groin nearly to the mammary line The patient was a fairly well nourished man of 41, the spleen was not enlarged

93 **Hematemesis in Peritonitis**—Gerasimovitch concludes from an experience with 11 patients and culling of the literature on the subject, that toxic
appendicitis, as Dieulafoy conte … s not a sign of
lent peritonitis In case of ap … l septic puru
… eritonitis it

is a sign that the bacteria have passed from the appendix into the stomach and indicates septicemia In the first category the hematemesis is due to diapedesis of blood, the erosions being secondary Besides the toxic changes in the walls of the vessels, the paralysis of the vasomotor system of the stomach, local congestion and increase in the blood pressure, all co operate in the production of the hemorrhage in the stomach Toxic hematemesis may be observed both in children and adults, and is a bad omen

94 **Periodic Paralysis**—Shtchepinsky has collected the data obtainable in the literature, and from this and a case personally observed he draws the clinical picture of periodically recurring paraplegia. He also discusses its nature, treatment, etc The usual remedies for nervous affections are generally ineffectual The essence of the trouble is still a mystery

95 **Duplication of the Heart Beat**—The case described can not be classed with Riegel's pulsus bigeminus nor with Leyden's hemisystolia, although it suggested both of them The patient was a man of 30, with hypertrophy of both ventricles, mitral and aortic insufficiency, endocarditis and irregular rhythm Death occurred in asystolia and general heart failure The heart was found in fatty degeneration, and there was a second, supernumerary apex It was the apex of the right ventricle, and, like a small aneurism, it increased in size at the end of the diastole under the impulse of the blood wave, becoming apparent in its interspace to the finger and eye, and thus inducing the first half of the double superficial heart beat The apex of the heart was practically split into two parts, the walls of the right ventricle tapering to a point, the pouch consisting merely of endocardium and pericardium with a thin layer of fat cells between them Doll has reported a somewhat similar case, although the left heart was the site of the anomaly in his patient This is the only other case of which the author has knowledge They show that in cases of double heart beat the causes may be various Most frequently, however, the supernumerary beat is "active," and is caused by the manifestations of bigeminus of the heart But cases do occur in which it has a "passive' character, and is due merely to some individual peculiarity

96 **Relations Between Physical and Intellectual Development**—Endo tabulates the findings of examination of hundreds of girls in a large school in St Petersburg, comparing their standing in the classes with their physical development He found it to be the rule that the girls who developed physically comparatively young were equally precocious in their studies The girls who menstruated at an early age usually graduated younger than their mates

100 **Compressed Yeast in Diabetes.**—Nandelstedt endorses Cassaet's experience in regard to the benefit to be derived from the use of *compressed yeast* in diabetes The thirst is reduced, the glycosuria subsides and these results persist even under moderate ingestion of carbohydrates

102 **Importance of Phosphorus in the Food**—Ototzkaya proclaims that when the food does not contain the requisite physiologic proportion of phosphorus, the system suffers from phosphorus starvation This is manifested in various ways, but chiefly in the nervous system The *normal proportion* should be one part phosphoric acid to five parts nitrogen The best means of determining the phosphorus balance is by the acidity of the urine In case it shows phosphorus starvation, vegetables and milk should be ingested more freely or some preparation of phosphorus should be taken as a medicine or with the food Phosphoric acid will be *found useful* and convenient for the latter purpose

109 **Extract of Green Oranges in Diarrhea.**—Vorontzoff describes 4 cases in detail out of a larger experience to sustain his assertions in regard to the great efficacy of an extract of unripe oranges in the treatment of severe diarrheas He has never heard of its application in dysentery, but it proved successful in several instances after failure of all the usual measures

APPENDICITIS IN CHILDREN.*

A. J. McCOSH, M.D.
NEW YORK CITY.

The subject of appendicitis has, during the last decade, received so much attention that one might suppose that there was but little more to learn concerning this rather puzzling disease. The term puzzling can certainly be justly employed, at least when speaking of its etiology, for we must frankly confess that our knowledge of this subject is but little further advanced than when the disease was first named appendicitis. We have, of course, learned much about its symptomatology, but even to-day I know of no surgical disease which more often offers surprises to the operating surgeon. The symptoms, or at least our interpretation of the symptoms, do not always indicate the actual condition of the appendix. I need not narrate to you cases where an appendix in a threatening or dangerous state is found when the symptoms have been comparatively trifling. It is this uncertainty which has mainly led surgeons to advise very early operative interference in all cases. No one can certainly tell at the beginning of an attack whether perforation has or has not occurred, or that gangrene of the entire organ will not result in the course of a few hours. Of course, if possible it is desirable to await the subsidence of the acute attack before removal of the appendix. The experienced surgeon can very often, by careful and frequent observations, safely carry the case along to the quiescent stage. This, however, can not always be done, and it is because of the exceptions that all surgeons are now practically agreed that the best results, both for preservation of life as well as of the strength of the abdominal wall, are obtained if the appendix be removed in the early hours of the attack.

Unfortunately, for many reasons, this practice can not invariably be carried out, and many cases are, and will continue to be, thrust into our hands, which have passed beyond the early stages of the disease. In such cases immediate operation will not always give the best results. There can be no doubt, I think, but that this rule of treatment should be almost absolute, provided that the infection is confined within or to the appendix itself. When, however, the infection has spread beyond, whether through a perforation of its wall or through the transudation of pyogenic bacteria through its inflamed coats, the propriety of advising immediate operation in every case becomes to my mind doubtful. A few years ago it was almost the universal feeling, I think, that the appendix should invariably be removed as soon as possible, no matter what the stage of the disease. Personally, I have always felt that there were many exceptions to this rule, and for a year or two past the drift of surgical opinion has been, I think, toward less radical views on this subject. This drift has become still more pronounced since the treatment formulated by Ochsner has apparently shown that many a life can be saved by judicious delay. While I can not quite agree with Dr. Ochsner in his extreme position, yet I feel very strongly that his teachings on this subject are well grounded, and if followed intelligently, but not blindly, will tend to lessen decidedly the mortality of grave cases of appendicitis. Certainly my own experience during the past year or two has led me to this conclusion, for I feel that in some cases postponement of the operation for some hours has immensely aided the recovery of the patient.

For example: In cases where there has been a sudden perforation with resulting peritoneal shock of extreme degree, the patient is in a very poor condition for a serious operation, and the peritoneum as well is not as resistant against infection as it will be some twelve hours or so later. In such cases, where there is apt to be much abdominal distension, a weak and rapid pulse with symptoms of general shock, the postponement of the operation for twelve or twenty-four hours will often result in a very decided improvement in the patient's condition, provided that starvation be absolute. The abdomen will generally become less distended and the pulse will improve.

You may ask what bearing have these remarks on the title of my paper, "Appendicitis in Children." It is mainly concerning this point of treatment, however, wherein I think the treatment of this disease in children should differ from that among adults.

I do not think that it is properly appreciated, among general practitioners at least, how frequently appendicitis occurs in children. The operating surgeon very often encounters in the course of his operations on young adults the history of attacks of abdominal symptoms dating back to their earlier years, which undoubtedly, arguing from the state of the appendix found at operation, were due to mild attacks of appendicitis. It is often difficult to distinguish cause from effect, and unquestionably in many of these cases the previous abdominal symptoms may have been caused not by appendicitis, but by attacks of catarrhal enteritis, yet, at the same time, there are others whose attacks of indigestion, which have recurred at intervals since early childhood, immediately cease after removal of an appendix, which distinctly shows the results of years of recurring attacks of inflammation. Of course, I appreciate the fact that the surgeon encounters but a minute proportion of the intestinal cases among children, and because of the few cases where a later manifestation of appendicitis leads him to attribute the digestive ailment of childhood to that cause, he is, perhaps, apt to overlook the millions of young patients who have manifested similar symptoms, and yet whose appendices have never shown evidence of disease I am willing to grant all this, but yet one can not avoid the conclusion that appendicitis in children is not an uncommon disease

---

* Read at the Fifty-fifth Annual Session of the American Medical Association, in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee: Drs. DeForest Willard, Charles A. Powers and J. F. Moore.

SYMPTOMS

The symptoms on which we most depend for our diagnosis of appendicitis are pain, local tenderness, muscular rigidity, vomiting and abdominal distension Pulse is often of value, as is also the temperature, but these two symptoms have more significance, perhaps, as regards the severity, rather than the actuality of the disease

In children, especially those under 10 or 12 years of age, the important symptoms, with the exception of vomiting, are apt to be masked Of course, the older the child the nearer the disease approaches the adult type

As my experience increases, I am becoming more and more convinced that appendicitis in young children differs somewhat from the same disease in adults The difference consists in the obscurity of the diagnostic symptoms and in the more insidious progress of the disease The younger the child the greater is the difference The correct diagnosis of disease in young children is often beset with difficulties Their inability to locate pain, their general restlessness and fretfulness and the unreliability of the significance of temperature are some of the causes of this difficulty

Pain—This, especially at the beginning of the attack, is, as a rule, probably as severe in the child as it is in the adult, but the uncertainty of its location impairs its value as a diagnostic symptom A general pain in the belly is complained of, the child not knowing exactly where it is located, at one moment pointing to the upper, at another to the lower abdomen It hurts everywhere, apparently not specially in the appendicular region This symptom, which of itself in the adult is of great significance, can only help us in the case of children by its combination with other symptoms In certain phlegmatic children there seems to be at times almost complete absence of pain Tenderness to pressure is apt to be equally doubtful The child generally dreads any palpation of the abdomen and complains almost as much in one part as another

Muscular Rigidity—This symptom, which is, perhaps our most important guide in the diagnosis of appendicitis in adults, is in children equally obscure The child is suffering pain and is prepared to cry out, and unless taken unawares, to tighten its abdominal muscles as soon as or even before the skin is touched by the examiner's finger The dread of being hurt causes the muscles to act on guard at almost any point of the abdomen If the utmost gentleness and patience are practiced, along with diversion of the child's attention, sometimes this symptom can be elicited and if certainly found, the diagnosis is at once confirmed

Vomiting—This is in children probably the most persistent symptom It at least is the most evident It is apt to continue in spite of starvation and medication If it does so, and persists for many hours without other adequate reason, and if it be accompanied by severe pain with absence of intestinal movement, the suspicion of appendicitis should be very great Persisting with severe abdominal pain for twenty-four hours or more even with intestinal movements the suspicion is still considerable The accompaniment of diarrhea is, of course, unusual, and points more toward a gastroenteritis, but still it may occur with appendicitis

If the abdomen becomes more and more distended the diagnosis of appendicitis becomes more and more probable Of course, for a perfect picture we should also have either local tenderness or muscular resistance, but, as already stated, these symptoms in children are apt to be wanting

The history of previous attacks of vomiting without adequate cause is of considerable diagnostic value The surgeon is, perhaps, apt to lay too much stress on the importance of such "bilious attack," but if he does so it is because very frequently in the cases on which he operates such a history is given It is important, however, that such attacks should be separated from those due to indiscretions in diet or an overloaded bowel

The diseases from which, it seems to me, appendicitis in children is especially difficult to differentiate, are gastroenteritis, with the gastric element most predominant, diaphragmatic pleurisy and basal pneumonia To my mind, certain of these doubtful cases are the most puzzling which the surgeon encounters In certain cases of acute indigestion or of gastroenteritis in its early stages, the differentiation from appendicitis is not easy The following points may be of some value The persistence of vomiting with severe pain for more than twenty-four hours, especially if there be no diarrhea, favors the diagnosis of appendicitis If the constipation be obstinate, the suspicion of appendicitis is generally sufficiently strong, should there be at the same time any one other symptom of this disease to warrant operation If there be diarrhea, it generally though not always, means that the case is at least less urgent

The existence of high fever probably rather favors gastroenteritis The blood examination may shed some light on the diagnosis The differential count is of more value than the mere leucocyte count There are however, so many exceptions to the general rule that personally I do not feel much confidence in blood examinations in young children Judging from a somewhat limited experience with the iodophilia test, it seems to me to offer more promise of valuable information than does either the leucocyte or differential count

As an example of the difficulties let me give the following history

Case 1—Girl, aged 4 During her first year there were several attacks of pain, vomiting and fever, lasting a few days and then passing off entirely In the second and third years these attacks occurred in milder degree The child was always carefully dieted In December, 1903, there occurred a sharper attack of pain, but there was no fever, no vomiting and no localization of the pain Since that time until April, 1904 about once a week the child would complain of a sudden, sharp abdominal pain which would last, however, but a few minutes It had no apparent connection with her meals and might occur when she was at play or out walking The digestion was apparently always good, and the child looked well There was considerable difference of opinion as to the diagnosis The father, who was a physician, and myself felt, however, that the chances of the cause of the trouble was a chronically inflamed appendix Accordingly, on April 11, 1904, it was removed It was found markedly diseased with the mucous membrane the seat of hemorrhages, and in a condition where perforation was imminent Since the operation the child has been entirely free from pain

To some of you it may appear foolish to dwell on the difficulty of differentiating appendicitis from diaphragmatic pleurisy, but it has been my lot to encounter several cases where it has been for a time quite impossible to distinguish between these two conditions Within the last few years I have been called on at least half a dozen times to either operate or decide concerning the propriety of operation in such cases In these half dozen cases time has shown that I have been as often wrong as right in my diagnosis, though, fortunately, in the cases that have proved to be pleurisy or pneumonia, a half day's delay has in every case saved the patient from an unnecessary operation Let me briefly relate three of these cases

Case 2—Boy, aged 8, who had usually enjoyed good health, was seized on November 5, in the early morning, with severe abdominal pain. He was at once given a dose of castor oil and throughout the day this was followed by two doses of Rochelle salts Later in the day vomiting began and continued more or less for twenty four hours There was some fever and a rapid pulse The bowels refused to move in spite of enemata, the abdomen began to distend, the pain continued The family physician called a children's specialist in consultation from New York (*the child was in the country*), and both were puzzled as to the diagnosis There was no cough, and no pain was assigned to the chest. The vomiting continued the abdomen was markedly distended, tender everywhere, and the child looked very ill Prepared to operate I saw the child toward midnight, twenty two hours after the commencement of the attack. It was a question as to diagnosis, the vomiting, absolute constipation, abdominal pain and tenderness made a diagnosis of appendicitis or intestinal obstruction probable There was a faint sign, however, of irritation of the lower left pleural surfaces, and we decided that a delay of a few hours was advisable. On the following morning the signs of pleurisy with probably a basal pneumonia were well developed. The child made a good though slow recovery

In this case the entire absence for at least forty hours of any abnormal chest sounds and the severity of the abdominal symptoms seemed markedly to favor intraperitoneal inflammation Until the abnormal chest sounds developed, diagnosis was impossible The case was a most puzzling one, and the delay in awaiting the pathognomonic symptoms would probably have caused a fatal termination had the appendix been involved

I do not feel that I can express views of much value as to the differential points between appendicitis and diaphragmatic pleurisy Of course, I am now referring to cases where abnormal chest sounds are absent Perhaps in cases of pleurisy a certain fixation of the lower ribs or stoppage of the respiratory movements at this point may be noticeable Perhaps also the child is more apt to toss about the bed than he would be apt to do were his appendix inflamed, but even in this latter condition the child is much more apt to be restless than is the adult If the child be inclined to assume the adult position of rest on the back with the thigh or thighs drawn up, the chances are in favor of appendicitis but, as already stated, children often fail to assume this posture The passive flexion and extension by the surgeon, of the thigh on the abdomen is in appendicitis even in children apt to be more resisted and dreaded than it would be in diaphragmatic pleurisy Sometimes, but not generally this symptom is of considerable value

Of course, if there be a tender spot or muscular rigidity, the diagnosis is easy If a boardlike condition of the abdomen develops we may be certain that the case is a very grave one of partial peritonitis

INSIDIOUS PROGRESS

Another point to be considered is the progress of the disease and its treatment The progress is often marked by insidiousness A case that is apparently mild will sometimes gradually drift, perhaps, without any alarming symptoms, into a grave condition with general septic peritonitis in spite of the most careful watching The pulse and temperature may remain normal, vomiting may cease, distension may not be marked and the bowels may even continue to move, and yet a general peritonitis is developing I am inclined to think that there is not the same effort on the part of Nature to wall off the inflamed appendix in children that so often occurs in adults Not only is this spreading tendency of the infection insidious, but it is often very rapid

I have encountered dozens of cases where the disease followed such a course The following are examples

Case 3—Girl, aged 13, was attacked in the early morning, April 21, 1904, with severe, sharp pain and vomited The temperature reached 99½ and the pulse 100 The bowels moved during the day, the pain toward evening became less, and the whole aspect of the child seemed improving, the pulse became slower and the night was passed comfortably In the morning, however, of the next day, in the course of a few hours, the whole aspect rapidly changed The abdomen became boardlike, the countenance assumed an anxious appearance, and the pulse rose in frequency and was very wiry There was also a tendency to vomit At 11 a m of that day, April 22, an operation revealed an appendix almost entirely gangrenous and a general suppurative peritonitis The child made a slow recovery

Case 4—Girl, aged 5, was seized on the evening of Nov 23, 1903, with abdominal pain She vomited, and during the night was restless, temperature 99½, pulse 90 The night was passed comfortably On the next morning the child seemed brighter, and asked for her breakfast, temperature 99, pulse 85, very slight pain was complained of When I saw the child at 11 30 of that day (November 24), *the abdomen seemed to me* rather tense, three hours later the tenseness was more marked and the child looked more ill Operation performed at 4 p m revealed a perforated appendix and a general peritonitis Thorough irrigation and drainage was employed and resulted in recovery

I could narrate many other cases where the symptoms have for days been of the mildest degree, and apparently all abating, when suddenly the conviction is forced on the physician, that some change has occurred, and operation then reveals a hopeless general peritonitis Dr Brannan's[1] instructive case is another example of treachery in the behavior of the appendix.

In the children there also seems to me greater liability to rapid gangrene Of course, in adults we often encounter cases where gangrene has been rapid and extensive, but this tendency strikes me as existing more frequently in children The following case is an example

Case 5—Girl, aged 11, in the evening of July 2, 1902, while in an automobile, was seized with severe abdominal pain During the night there was slight vomiting and some fever (101 degrees) On the following morning the abdomen was rather tense, and while the pulse was not over 80 Dr W K. Draper felt that immediate operation *was demanded The tenseness* of the abdominal muscles was suspicious The operation was done just twenty hours after the appearance of the first symptoms, and the long appendix was found absolutely gangrenous from its tip to its very base and even beyond A spreading peritonitis had begun but the child made a good recovery

REMARKS

Because of this treacherous behavior of the inflamed appendix in the child as well as the inferior tendency to limit the inflammation by adhesive peritonitis, I feel very strongly that in every case of appendicitis in children immediate operation should be advised No matter what the stage of the disease may be, I feel it much wiser to operate at once, and not delay in hopes that at a later date an interval operation may be performed This advice is in accord with that of many surgeons for appendicitis at any age, but, as already expressed in this paper, I am not entirely in accord with such views, except in cases of children The older the patient the less tendency there seems to me to be to spreading peritonitis, and the more unfavorable are the results of operation in grave cases

---

[1] Medical Record April 30 1904

My own experience with operations for general septic peritonitis has demonstrated to my own satisfaction that the results of the operation on young adults, if they be rapidly performed are apt to be favorable, while those on patients over 10 or 15 are almost invariably fatal

I thought it might be of interest to give the age statistics of 1,000 cases of appendicitis, at the time of their operation While my operative cases number more than this, I have not included those of the last few months, as a round number like 1,000 seemed to me more convenient I have also tabulated in 1,500 cases which I have personally seen, the ages at which, as far as could be ascertained, the first symptoms of inflammation of the appendix manifested itself

TIME OF OPERATION OF 1,000 CASES

Age in years	No of cases	Per cent	Age in years	No of cases	Per cent
1 2	3				
2 3	1		15 16	14	
3 4	7		16 17	24	
4 5	6		17 18	28	
			18 19	27	
1 5	17	1 7	19 20	20	
5 6	8		15 20	11'	11
6 7	10				
7 8	12		20 25	176	17 6
8 9	10		25 30	176	17 6
9-10	11		30 35	149	14 9
			35 40	99	9 9
5 10	51	5 1	40 45	65	6 5
			45 50	35	3 5
10 11	15		50 55	15	1 5
11 12	19		55 60	11	1 1
12 13	15		60 65	6	0 6
13 14	21		65 70	2	0 2
14-15	15		70 75	1	0 1
10 15	85	8 5			

RATIO OF AGE TO FIRST SYMPTOMS IN 1 500 CASES

The proportion which had the first symptoms in the first year is 003 per cent of all cases,

In first 2 years	1 33
In first 5 years	7 5
In first 10 years	17
In first 15 years	31
In first 20 years	46
In first 25 years	54
In first 30 years	70
In first 35 years	82
In first 40 years	89
In first 45 years	94
In first 50 years	96
In first 55 years	98
In first 60 years	99
In first 65 years	99 5
In first 70 years	99 75
In first 75 years	100

From these statistics it will be seen that young adult life furnishes the largest number of cases of appendicitis In those that demanded operation, the greatest number occurred between the ages of 20 and 35, the proportion being over 50 per cent After 35 the proportion of cases becomes rapidly and progressively smaller between 40 and 50 being but 10 per cent

Before the age of 20, the proportion is 26½ per cent , before the age of 15 years, 15 per cent , before the age of 10 years, 068 per cent The youngest cases in my series were 12, 12½ 16 and 20 months, respectively Over 60 years the proportion was nearly 1 per cent (009) The oldest case was 72½ years

THE DIAGNOSIS OF APPENDICITIS

SHOULD THE APPENDIX BE REMOVED WHEN THE ABDOMEN IS OPEN FOR OTHER CONDITIONS? *

FLOYD W McRAE, M D
ATLANTA, GA

So much has been written and said about the ease of diagnosing appendiceal disease, so little stress has been laid on the occasional difficulty of making a correct diagnosis, that condemnation is heaped on those who fail to appreciate the real condition Sight is lost of the fact that the best diagnosticians and abdominal surgeons are occasionally put to it to determine whether the appendix is the seat of the trouble or not Mistakes are made by the very best surgeons Each of us should profit by his own mistakes and the mistakes of his fellows, and each of us should be willing to give the whole profession his experiences, fairly and unreservedly

I have only removed 272 appendices of which I have accurate records In forty instances, multiple operations were done at the same seance, and in many of them the diseased condition of the appendix was not definitely diagnosed before opening the abdomen.

In 71 of these cases appendiceal disease was associated with or masked by one or more of the following conditions In 4 cases by renal calculi, in 5 cases by gallstones or gall-bladder adhesion, in 18 cases by vague symptoms of indigestion, biliousness and indefinite colic, in 5 cases by frequently recurring dysentery or rectal disease, in 3 cases by acute intestinal obstruction, and in 2 cases of typhoid fever, in 12 cases by floating and diseased kidneys, in 1 case by acute septic nephritis, in 1 case by retroperitoneal tubercular abscess, in 3 cases by tubercular peritonitis, in 11 cases by marked menstrual disturbances, in 11 cases by disease of the uterine appendages, in 2 cases, retrocecal herniæ were mistaken for appendicitis, the appendices only becoming involved incidentally In 2 other cases no diagnoses were made, but exploratory operations demonstrated appendiceal disease In 1 case, in a young girl, a ruptured dermoid cyst was diagnosed appendicitis, and in another, a right salpingitis was diagnosed appendicitis

I have done at one sitting, on the same patient, without unusual shock or prolonged convalescence, the following operations Dilatation of the cervix and curettement of the uterus, removal of a number of enlarged cervical glands and hemorrhoids, anchoring a floating kidney, and removal of a diseased appendix At another time I removed at the same sitting a diseased appendix, and did a gastroenterostomy for contraction of the pylorus consequent on gastric ulcer two years before

In the process of evolution, medicine and surgery have reached a stage of development when such terms as colic gastralgia, acute indigestion and intestinal indigestion can no longer be loosely used in diagnosis without subjecting the user to just criticism They are but symptoms of some definite chemic or mechanic defect in the digestive process, and careful investigation would reveal the underlying pathology, i e, a contracted pylorus, gallstones or appendiceal disease, or partial intestinal obstruction from old adhesions

Since Edebohls, Deaver and other leading members of the surgical side of the profession called attention to

---

* Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Surgery and Anatomy and approved for publication by the Executive Committee Drs DeForest Willard Charles A Powers and J D Moore

the frequent association of appendiceal and pelvic inflammatory disease, a vigorous discussion has been waged pro and con, the one side claiming that inflammatory disease of the appendix is apt to involve the uterine appendages, and that disease of the appendages is often the direct cause of inflammatory appendiceal disease, while the other side argues with equal zeal that the conditions are separate and distinct and seldom corelated They hold, therefore, that the appendix should not be interfered with when bound up in adhesions due to pelvic inflammatory disease, and that the freed appendix is not likely to give future trouble

Baldy, in a paper read before the Southern Surgical and Gynecological Association in Atlanta, December, 1903, argued very earnestly this side of the question

Such argument, it seems to me, is contrary to our knowledge of these diseases, at variance with the best clinical experience, and is conducive to incomplete surgery and unsatisfactory results

Kelly, in his classical work on gynecology, gives the opinions of a number of the leading surgeons and gynecologists in this country on this question Most of them were of the opinion that the removal of the appendix, unless markedly diseased, should not be a routine practice, the author agreeing with these

The by-no-means infrequent incomplete cures following pelvic operations where appendices *have been* left, condemning the victim to chronic invalidism, the ever-present anxiety and danger of a severe and fatal attack of appendicitis, have impressed me with the advisability of removing the appendix during all pelvic operations when it shows the least evidence of disease or when it is accessible and can be removed without undue prolongation of the operation or hazard to the patient

Had I an appendix, I would feel that any surgeon opening my abdomen and leaving the organ, if accessible, had grievously sinned against me I entertain this same feeling and a similar opinion for members of my own family Holding such an opinion, entertaining such a feeling for my own loved ones, could I advocate less for the loved ones of others Nowhere is the Golden Rule *more applicable* than in surgery, and the surgeon who does more or less for those who submit their health and lives unreservedly to his skill and honor than he would want done for him or his, under similar circumstances, is recreant to the trust reposed in him, and is unworthy the respect and confidence of honest men and women

CASE 1—Mrs P W G, 25 years old Gave history of having ovaries removed per vaginam one year ago Since then has had repeated light attacks of pain in the McBurney region and in right side of pelvis Chronic indigestion for several years At times has a dragging sensation over right kidney Admitted to St. Joseph's Infirmary June 26, 1903 Has marked tenderness over appendix, slightly movable right kidney uterus free, it and cervix being atrophied

Operation—June 30 1903 Gas ether McBurney gridiron incision, appendix found in pelvis was thickened, very much enlarged, and attached by small adhesions Doyen amputation Layer closure

CASE 2—Miss E S, 35 years old Negative family history *Menstruation began* at 13 years, was regular but always painful, so a curettement was done eight years ago For the past four or five years she has suffered for five days before and five days after menstruation, with often severe pains over left ovary A double salpingo oöphorectomy, June 1903, relieved her of all pelvic pain Dysentery from November to February nine years ago For years she has had general colicky pains lasting from a few hours to a day or so Two years ago was in bed a month with "bilious" colic and suffered great abdominal pain Five months after ovaries were removed she was taken with pain in epigastrium, which became localized in a few hours to appendiceal region Since then any jolting or exercise caused pain in the *left* iliac region A similar attack began ten days ago and pain continued until admitted to St Joseph's Infirmary March 25, 1904

Operation.—March 28, 1004 Gas ether McRae transverse incision with longitudinal opening of peritoneum, enlarged by a transverse cut There were thick, dense adhesions of omentum, passing from cecum into pelvis to stump of removed ovary, a retrocecal appendix was dissected out of adhesions by working over and behind border of friable cecum Appendix tore out of cecum, its lumen being closed This umbilication was covered over by peritoneum and adhesions, a cigarette drain being carried to this point Peritoneum closed with No 1 catgut, silkworm gut being used for the remainder Very little discharge followed patient going home well April 25

CASE 3—Mr W L L, 30 years old, traveling salesman History of typhoid at 7, rheumatism at 10 years of age From five to two years ago he had a diarrhea each spring, ending in a dysentery, all lasting from five to eight weeks, being confined to bed three or four days with the latter Eighteen months before operation he awoke with slight pains in appendiceal region, which soon went to left iliac region and passed off in about five hours No nausea or soreness In two months a similar attack, lasting six hours, another in two months lasting eight hours, etc, an attack about every two months, each getting a little longer Never any nausea or soreness after the third day, until six months ago, when he was in bed ten days with nausea, marked pain in the McBurney region, with a spasmodic pain in rectum, penis and perineum Was sore for a week thereafter Similar attack, lasting six days, two months later with daily formation of gas in cecum since Under stomach specialist for weeks, without relief

Admitted to St Joseph's Infirmary Aug 14, 1902 Appendix could be felt (?) with thickening of cecum urine contained a few casts

Operation—Aug 21, 1902 Gas ether McBurney gridiron Omentum and large intestine only found at wound A median incision was made when stomach and transverse colon came into wound, the latter could not be traced to the left, but seemed to enter pelvis on the right side At first, no small intestine was found, was later located matted in pelvis and collapsed like an obstruction Tracing the bowel for a short distance a small Meckel's diverticulum was found, beyond this intestine was thickened, rough, granular looked tuberculous, and soon became firmly fixed in pelvis surrounded by adhesions, so could not be brought up

Through the McBurney wound, appendix was found in pelvis surrounded by adhesions Doyen amputation done Everything bled freely Abdomen flushed with saline and each wound was closed in layers, a cigarette drain being placed in the lower angles

Patient very much depressed for twenty four hours Rallied and made uneventful recovery In two months weighed more than ever before

CASE 4—Mrs H V J, 41 years old Family history good Oldest child 23 years Was in labor twenty four hours, placenta adherent to right side and had to be removed, was very sick for several days following Never strong thereafter, having a dragging sensation in lower abdomen and pain when wishing to defecate instead of normal reflex Second child 21 years old Had hemorrhage after labor and was in bed five weeks Two years later menses became irregular and she aborted at three weeks, was weak and had a leucorrhea thereafter, and when she walked, hemorrhage returned Two years after abortion was in bed three weeks, at beginning of pregnancy, from weakness Three months prior to labor, was swollen all over" and could not lie down on account of difficult breathing Four years after this labor was in weakened condition, when lacerated cervix and perineum were repaired, she becoming very much better, but could not walk long at a time Was told she had prolapsus uteri For past seventeen years menses have been regular, but she always had a dragging in pelvis and acute, general abdominal pain, which came on irrespective of quietude and lasted one to three hours, being relieved by a hot douche, enema or hot applications to abdomen One year ago was in bed a day with acute pain over appendix and thereafter had a tearing pain in appendiceal region, when she rested on left side, much walking would also cause it

Present Illness—On April 21 was taken with acute pain in the McBurney region, which increased until relieved by morphia six hours later In another six hours pain had returned and increased until bowels acted

Admitted to St. Joseph's Infirmary April 23, 1903 Temperature 100, pulse 85, nauseated, weak, tender over right side of abdomen Rectal feeding until operation, May 10

Operation—Gas ether Considerable débris from curettement Laparotomy Appendix found adherent to right ovary and tube, was much enlarged, brawny, tearing from slightest pressure Appendix was too rotten to make cuff, so a chromicized catgut ligature was tied about same, end cauterized and stitched over Right tube enlarged and thickened, ovary was a cyst, size of an orange, both were removed, the raw surface being closed over and stump stitched to abdominal wall to support the retroverted uterus Layer closure Uneventful recovery

"Now in better health than in twenty years"

CASE 5—Mrs D R W, 33 years old Bilious fever and later dysentery, seventeen years ago Eighteen years ago she fell six feet and was unconscious for several hours and menstruation was delayed for six months For twelve years after marriage she had a continuous leucorrhea, which was profuse at times During summer of 1899 she had abscess of both vulvo-vaginal glands, followed by severe pain over left ovary which continued, at intervals, until the fall, when an application of tincture of iodin and carbolic acid was made to interior of uterus Peritonitis resulted, confining her to bed for two months, opiates being used to relieve pain In January, 1900 left pyosalpinx was removed, after freeing adherent intestines, which formed a roof to that part of the pelvis Was in good health then for a year, when she had la grippe, and tuberculosis was suspected

Present Illness—For two or three years has had attacks of pain in right kidney, lasting from two to three days For a year these have been frequent, with almost constant aching, pain being relieved when she replaced the floating kidney Has eaten little for the past two years The smallest amount of food causes pain in right hypochondriacal region

Operation—March 29, 1904 Curettement, and sphincter divulsed Ferguson incision and delivery of right kidney, which was large, hard, and capsule firmly adherent Posterior flap of capsule stitched to muscles and anterior flap sutured between edges of wound, which was closed with silkworm gut suture a cigarette drain being used

A McBurney gridiron incision was then made, when the cecum and a long appendix, surrounded by adhesions, were found under the border of the liver, the colon passing to left hypochondrium, thence to right iliac region and into pelvis Layer closure and uneventful recovery

CASE 6—Mrs J C H, 35 years old

History—Since she can remember, has had a chronic laryngitis Always a dysmenorrhea, which was not so bad after first child, which is 11 years old Has had hemorrhoids, almost a continuous leucorrhea and backache since birth of this child During second pregnancy, eight years ago, she had a violent pain, like colic, in right side of abdomen, a mass soon developed in the right iliac region which was pronounced a "tubal abscess,' which later "discharged through uterus" while she was pregnant! She was in bed nearly a year At times since, has felt this mass in side of abdomen, had frequent attacks of colic, thought to be ovarian, but was conscious of two distinct kinds Nausea, but no vomiting Has not been able to walk much for several years on account of pain, and riding was torture Amputation of cervix and ligation of piles one year ago

Admitted to St Joseph's Infirmary Jan. 13, 1904 Had right floating kidney and tenderness over appendix

Operation—January 14 Gas ether Ferguson incision and delivery of right kidney, posterior flap of capsule sutured to muscles, anterior flap brought between edges of wound Silkworm gut closure, with drainage McBurney gridiron incision Appendix found in pelvis, surrounded by adhesions and strictured near base Doyen invagination amputation, raw surface closed over and wound closed in layers

These appendices ought to have been removed when the first operations were done, and might have been without difficulty, and far less danger than submitting to second operations necessitated The patients would have been cured, and the operator would have saved himself the discredit of "successful operations that failed to cure the patient"

While laying more stress on removal of the appendices before closing the incisions after pelvic operations, I also want to put on record as holding the same view with reference to other abdominal operations How often is the focus of infection that lights up gall-bladder disease an inflamed appendix! The frequent association of chronic appendicitis and movable kidney is now so well recognized as to hardly require mentioning

Where the two pathologic conditions obtain, the correction of one seldom cures the other If I am not mistaken, I did the first combined operation for removal of the appendix and the anchoring of a movable kidney through the same incision I reported two cases before the meeting of the Southern Surgical and Gynecological Association in Atlanta Both the cases then reported have been kept under observation, and both seem to have been perfect cures

I have latterly, however, preferred to make separate incisions for each operation, as it requires little more time, and the work can be much better done

---

FACTORS IN THE MORTALITY OF APPENDICITIS *

JOHN B DEAVER, M D
Surgeon in Chief German Hospital
PHILADELPHIA

Infectious inflammation of the vermiform appendix has occupied the attention of the medical profession for many years, has been discussed and debated at hundreds of society meetings, and has furnished a fertile theme for thousands of good, bad and indifferent medical authors Books have been written on the subject in France, in Germany, in England, and in the United States describing the historic episodes, the pathology, the diagnosis and the treatment of the disease

The vermiform has been cut off, tucked in and turned inside out, the patients have been purged, narcotized, packed in ice or baked in poultices, they have been starved or instructed to walk on all fours like quadrupeds, leucocytes have been gazed on through the barrel of the microscope and tested for glycogen, and the urine assiduously examined for indican, acetone or albumin, and yet, with all this study, all of the examinations, a fatal appendicitis caused by a little 8x1 cm organ has doomed thousands of suffering humanity to an early and untimely end The lack of common sense and ordinary intelligence in eliciting the history of the attack or the neglect of the use of the only instrument of any service in the diagnosis of this disease, the palpating hand of the practitioner, is responsible for much of the mortality

ERRORS IN DIAGNOSIS

Errors in diagnosis are to be considered under two headings

1 The time that elapses between the onset of the disease and the production of sufficient symptomatic reaction to attract the attention of the patient

2 The delay of the physician himself in reaching a diagnosis

In regard to a period of latency, it is undeniable that in a few cases the most prompt diagnosis and early operation discloses advanced pathologic changes, with a thin, seropurulent fluid throughout the peritoneal cavity The appendix may show little macroscopic evidence of disease, or may be perforated and gangrenous Many of these patients recover, some of them die, and in the latter event neither the practitioner nor the surgeon can be reproached for an error in judgment They were operated on at the time of election, and were the few exceptions to the rule Some patients suffer habitually from colicky pain in the abdomen, due to intestinal fermentation and the accumulation of flatus some women suffer abdominal pain at the menstrual epoch, many patients have acquired the too ready habit of using laudanum or paregoric for every abdominal ache or pain, and especially when the sufferer is a child

In such the onset of serious symptoms may not have given warning that something unusual and more severe has occurred until the disease has advanced into the later stages It is the duty of the practitioner to continually and persistently impress on his patients the danger that lies in the uncontrolled use of opiates, particularly in children, in whom the percentage of the more severe grades of appendicitis is greater than in adults

The failure to make an early diagnosis of acute appendicitis is responsible for most of the factors entering into the mortality of the disease With a nearly unanimous agreement among experienced surgeons that operation is indicated in the early hours of the attack, the great importance of prompt diagnosis can be clearly perceived

In every sudden abdominal pain the probability of an appendicitis should be borne in mind, and no other diagnosis considered until that disease can definitely be excluded

An abnormal position of the appendix may make the diagnosis difficult at times, and in certain of the fulminating types when there is a very obscure history, it is often difficult to locate the source of the peritoneal infection Salpingitis, cholecystitis, perforated gastric ulcer, acute pancreatitis, intestinal obstruction, mesenteric thrombosis, enteric fever, basal pneumonia diaphragmatic pleurisy and a few other conditions are often confused with appendicitis, but the history, the onset and the sensation experienced by the palpating hand will usually differentiate the true condition

The subject of the differential diagnosis is outside the province of this paper

In children abdominal pain is of such common occurrence that an appendiceal colic is very apt to be unrecognized This is especially true in the first year of infancy, and cases with comparatively mild local symptoms are certainly rarely diagnosed If the process goes on to abscess formation, the condition is more readily discovered if the possibility of an appendicitis is not forgotten

One of the greatest fallacies which has ever been propagated to account for appendiceal symptoms is rheumatism In an extensive experience with appendicitis I have always found true appendiceal symptoms to be due to a diseased appendix in every case, even where rheumatism has been held responsible for the symptom-complex prior to operation Without dilating further on the diseases that may be diagnosed when appendicitis is the true lesion, it may be well to consider why such confusion continually arises

Acute appendicitis in the great majority of cases is easy of perception, even in the earliest stages The disease is so prevalent, the cases observed by every practitioner of medicine so numerous, that one can but wonder at the continuous stream of pus-bearing abdomens that flow into a large hospital yearly Every physician

---

* Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Surgery and Anatomy and approved for publication by the Executive Committee Drs DeForest Willard, Charles A Powers and J E Moore

has had one case of severe acute appendicitis, which may have caused difficulty in diagnosis, has referred the patient to a surgeon, stood beside the operating table and observed a highly inflamed appendix, perhaps gangrenous, removed And yet this same physician a few months or years later is called to see another patient in the throes of appendiceal colic, knows well what the disease may lead to, and yet gazes, fascinated, as if by a rattlesnake, temporizes and dallies until the right iliac fossa becomes "ripe" and filled with pus

The history of the onset and early hours of appendicitis and the results of palpation of the abdomen are signboards pointing the way, and if misinterpreted the occurrence of peritonitis, even though local in extent, may confuse the most able clinician To paraphrase Dr Mumford "Do not coquet with an infected appendix, cut it out and you will never regret it"

But if the hemocytometer and microscope are used to diagnose appendicitis to the practical exclusion of clinical experience, then, indeed, will the mortality of appendicitis be in the ascendency, and, furthermore, if the laboratory is wholly relied on to determine the time of operation, then will there be a still greater increase in the mortality I do not wish to be considered as opposing scientific aids to practical medicine, but rather as objecting to the exaggeration of their importance in the diagnosis of acute surgical diseases at a time when operation promises a nearly absolute cure

Twenty thousand leucocytes is considered by most hematologists to be the minimum count to diagnose pus with certainty, but by the time these figures have been reached, the abscess is crying out to be released Only recently, in a French surgical journal, it was stated that "those who doubt the clinical value of the leucocyte count are those who have been content with an occasional count The figure must remain at 25,000 or above for several days at least to affirm the positive presence of pus The leucocytosis increases if the abscess has a tendency to spread and when the abscess perforates into the abdominal cavity the leucocytosis subsides at first, but rises again as peritonitis develops" I can not imagine a surgeon in this country waiting in cold blood for peritonitis to develop It is just this class of statement to which I refer in my remarks

The concluding lines of an editorial in a recent number of THE JOURNAL of the American Medical Association exactly states my views "Some of the old-trained delicacy of observation could accomplish as much, with less waste of time, as is now accomplished by means of intricate mechanical appliances"

METHOD OF TREATMENT

The next question that arises after the diagnosis of appendicitis has been established, is that concerning the method of treatment to be pursued We must face a condition not a theory, because the issue of an attack of appendicitis can not be foretold with even the slightest amount of assurance, nor can the nature of the pathologic lesions of the appendix be deducted from the clinical manifestations We are not governed by the same reasons that influence us to perform the radical operation for the cure of a hernia, or for the removal of the uterus for a fibromyoma In appendicitis we face the probable consequences of those dreadful factors in the mortality of the disease—suppuration, gangrene and perforation of the appendix, with varying lesions of the peritoneum Early operation is, therefore, a conservative, not a radical, procedure

To delay operation until there is evidence of the presence of pus, to defer it also if there be any doubt as to the pus formation, or to wait until the leucocyte count rises or falls, is unjustifiable and nearly criminal

Such statements, however, have become hackneyed, as I believe that every surgeon of any experience, in this country at least, advocates the immediate operation if the case is seen early

The principle may be stated That in every case of appendicitis, seen early, operation is indicated regardless of the mildness of the attack and regardless of the severity of the attack in the absence of a spreading peritonitis

In stating as the principle of the treatment of appendicitis that the diseased organ should be removed immediately if the diagnosis has been made early, I am not unmindful of the fact that, speaking broadly, the attending circumstances are of great significance in many cases in determining the treatment to be adopted It is sometimes impossible to institute early operative procedures for one of several reasons The patient may not live within reach of a competent surgeon, he or his family may not be willing to have surgical treatment pursued until it has become evident that the patient's only chance of recovery is by operation, or there may be some serious underlying disease, such as advanced nephritis, diabetes, tuberculosis, etc, that forbids active measures Under such circumstances expectant or so-called medical treatment is the only alternative

Operation is contraindicated in those cases of diffuse peritonitis in which the abdomen is distended, the temperature high, the pulse rapid and of high tension, the patient's expression most anxious and indicative of very serious intra-abdominal infection, the bowels constipated and unable to cause the expulsion of flatus and in which vomiting is continuous, and tenderness is diffuse over the entire abdominal wall The tongue is dry and brown, the skin dry, and frequently delirium is shortly followed by coma and death

In another class of cases the features are pinched the skin cold and clammy, the temperature is normal or subnormal, the pulse rapid and thready, the leucocytes are below normal in number and the abdomen hard and rigid throughout, without much distension In this type of diffuse peritonitis the patient is in a state of collapse, and operative interference is almost always followed by a fatal termination

In every case of acute appendicitis the peritoneum reacts to the irritant and secretes a serous effusion, the quantity of which depends on the amount and virulence of the bacteria or their toxins, or both Nature then offers two measures by which the toxins may be rendered harmless and the patient recover The first and most common is by the formation of protecting and encircling adhesions which, for a time a least, confine the infection to a localized area and thereby limit the amount of absorption But sooner or later the purulent products extend in the direction of least resistance, thus offering a much wider field of absorption Nature does her best in the beginning, but the aseptic scalpel of the surgeon must complete the cure by providing an external opening for the pus

The other method I referred to consists in the peritoneum reacting to the irritation by its entire effusing surface causing the accumulation of an amount of fluid proportionate to the irritation, diluting the toxins and furnishing an antitoxin which endeavors to check bacterial invasion after perforation of the appendix (Moszkowicz) If the operation has been done in time, this effusion explains the rapid recovery of the peritoneum from infection after removal of the appendix.

If operation is delayed, the swollen belly, filled with thin serous fluid, so often encountered at the operating table, shows that there is no tendency to form adhesions, and that large amounts of virulent bacteria or their toxins are invading the abdominal cavity. Failure to remove a collection of pus in the right iliac fossa, no matter where the locality nor what the quantity of pus, is always a source of the greatest danger and exerts a powerful influence on the death rate of acute appendicitis.

Nearly two years ago I placed a number of cases of appendicitis with abscess on the rest or starvation treatment, without obtaining any results beyond an aggravation of the symptoms and an increase in the mortality. It was observed that even the etherization of these cases was more difficult than usual, and I have frequently remarked to my students that the way a patient takes ether is often an index as to the gravity of the intraperitoneal lesion. After opening the abdomen, it was a serious problem how to dispose gauze pads before opening the abscess, there were so many adhesions, not so complete as to effectually wall off the pus, but enough to interfere with the placing of the gauze. It was also found that the infected coils of intestine were so friable that the breaking of any adhesions would cause the serous coat to peel off. The latter remark might suggest that in the presence of a walled-off abscess the peritoneal cavity should not be opened, but it is often impossible to gain access to these abscesses in any other way, situated as they are behind the cecum and colon and well to the median line side of the flank.

I do not imply that every case of peritonitis must be operated on, but, on the contrary, as I have previously referred to in this paper, that operation in the presence of an acute general peritonitis of seventy-two or more hours' duration, is attended by great risks to life, and, therefore, it is often wise to defer operation in the hope that the inflammatory process will become localized. Adhesions may form about the source of infection, and the peritoneal effusion take care of the general cavity.

Such a result is best promoted by rest and the restraint of peristalsis. When these cases are operated on at the end of three or four weeks, or at a time dependent on the degree of recovery from the acute attack, the condition of the belly cavity in my experience does not agree with that found by some writers. Instead of reducing the operation to one like the ordinary interval operation for appendicitis, I have found it one of the most difficult. Inflammation of the peritoneal cavity of such severity as to warrant delay in operation must be accompanied by effusion and exudate and the organization of such pathologic tissue is certainly one of connective tissue proliferation with the production of numerous adhesions.

When a nearly normal peritoneum is discovered at the interval operation, with perhaps a small localized abscess, it is quite apparent that the primary lesion could not have been a severe one. Bowel necrosis from pressure of pus, metastatic abscess of the liver, suppurative pylephlebitis, purulent lymphangitis and lymphadenitis, septic pneumonia, parotitis and pyemia are well-known to all of you as occasional results of late operation.

I have referred to the fact that difficulty in etherization is in direct relation to the gravity of the abdominal lesion. The board-like rigidity of the abdominal muscles never relaxes, the patient becomes cyanosed, the bronchi filled with mucus, and at times even respiration ceases. These cases influence the mortality by insufficient relaxation of the abdominal muscles impeding the manipulations of the surgeon, making gauze packing difficult and favoring the spread of infection.

Following operation the irritation and congestion of the bronchi favor their infection and the production of an inspiratory pneumonia. For this reason it may be argued that ether is not the best anesthesia for such cases, but after a thorough trial of nitrous oxid gas, I find the combination of ether and oxygen, always followed by oxygen, to be the most satisfactory.

The presence of pus is by no means necessarily fatal if the operator is experienced in dealing with this class of cases. The salvation of the pus case lies in proper drainage with protection of the healthy peritoneum during and after the operation. Successful drainage depends on a sufficient amount of gauze properly placed with a glass tube in the pelvis if necessary. Gauze that does not drain is more harmful than beneficial, too much gauze, and especially if improperly placed, only adding to the number of adhesions and to the chances of an intestinal obstruction shortly after operation. The management of the gauze is also an important factor in the mortality of appendicitis. The time and method of its removal are important points to be considered in every case in which gauze has been employed. The tendency is to remove the gauze entirely too soon, and as this always requires force, adhesions are broken up, and infection is liable to be spread from the secreting pus cavity. To remove a gauze drain at the end of twenty-four or forty-eight hours is, in the majority of cases, removing the main hope of the patient.

Where a large localized collection of pus is accompanied with what appears to be a beginning general peritonitis with injection of the serous coat of the bowel and a considerable quantity of cloudy exudate, the question of general irrigation is to be considered. In the majority of cases the entire peritoneum is not infected and this membrane can better take care of diseased products unaided. I rarely irrigate such an abdomen.

Failure to explore the pelvis is another factor of no little importance. In very many instances a collection of cloudy serum or pus may occupy the pelvis, and unless discovered and proper drainage provided proves a menace to the patient. Secondary collections in other localities must be evacuated and drained.

Acute intestinal obstruction following operative interference in acute appendicitis is one of the most serious of the sequelæ of this disease. The gravity of the condition depends on the fact that a second operation is always urgently demanded. In the presence of an infected area of the peritoneal cavity, and with the already weakened resistive power of the patient to shock, it would naturally follow that the mortality of acute obstruction is high. Following the evacuation of a circumscribed abscess, the exudate which has served the useful purpose of restricting the spread of infection becomes a menace by its liability to organize into connective tissue. Such adhesions may give rise to disastrous intestinal complications. By their mere adhesion to portions of the bowel they inhibit peristalsis, and by their contraction cause intestinal obstruction. Injury to the free edges of the omentum or mesentery may result in their adhesion to the small bowel with a consequent obstruction.

The greatest number of acute obstructions of the intestine follows those cases in which an abscess existed at the time of first operation and in which drainage was used This furnishes a most potent argument in favor of the early operation with removal of the appendix before the extension of the inflammation gives rise to a serofibrinous exudate As I have remarked in a previous paper, "walled-off" is an expression often used by physicians as a term of congratulation, but it also denotes a most fertile condition for a future intestinal obstruction

I find obstruction to follow acute appendicitis in about 1 5 per cent of cases, and to be due, of course, primarily, to bands of adhesions, but also predisposed to by too early and injudicious feeding of the patient The resulting increased peristalsis and general intestinal disturbance cause congestion and swelling of the intestinal wall further narrowing the lumen of the bowel

Fecal fistula may follow cases in which an abscess collection causes pressure necrosis on the bowel, when the cecum is directly involved in a gangrenous process, or where the entire appendix has not been removed While such fistulæ do not directly have great influence in increasing the mortality, yet the operation which must later be undertaken for their repair is by no means devoid of risk

Finally, the great percentage of extensive drainage cases are followed by hernia for which mechanical appliances are of no avail Hernia requires a secondary operation which is more formidable than the primary one

In conclusion, I would again urge on you to advocate the early operation for appendicitis The tendency of many surgeons at the present time to occupy a sort of middle ground should not be imitated by the rising generation I know of successful surgeons who operate immediately when a case reaches the hospital, and yet who formulate and teach their students so many rules for the treatment of appendicitis that a text-book of surgery must be carried around in the medicine case Furthermore, an expression of opinion from members of a surgical association is always of interest to the general practitioner Too often the discussion of a paper is limited to congratulatory remarks, surgeons whose teaching is of infinite value preferring to praise or conciliate a friend rather than to boldly announce their own ideas and practice

DISCUSSION

ON PAPERS BY DRS M'COSH, M'RAE AND DEAVER

Dr. Ernest Laplace, Philadelphia—I believe that in every fatal case there was a time when, if the operation had been performed, the patient's life might have been saved, but somebody has been guilty of allowing that moment to pass by I deny that any one can establish the fact that there is pus in the abdominal cavity, that there is a developing case of peritonitis, or can deny the occurrence of fulminating appendicitis If we accept this it follows that by delay we are in a great state of uncertainty as to the future of that patient Taking this for granted, it is useless to deny the necessity of operating during the course of the disease You should do the operation and use common sense, according to the rules on which our knowledge of surgery is founded In every case, when possible, I believe in the dry method of operating I drain and pack, and remove the gauze on the eighth day When peritonitis occurs, one is face to face with another problem Another disease has stepped in, and that is general septicemia The patient may die from general septicemia although the local peritoneum has undergone improvement A patient may die with tetanus even though his thumb has been amputated These cases should no longer exist when a primary operation has been performed I treat general peritonitis on the same common sense principles that I would erysipelas I watch it continuously and treat it locally I flush with sterile water I wish to say that the day has come when we must abandon the saline solution, because it may irritate the inflamed peritoneum I have satisfied myself as to this absolutely by experiments on a man with one good eye and one bad eye The solution irritates the inflamed eye but not the healthy one I practice repeated irrigations after the operation through tubes above and below and in each lumbar region Leucocytosis is of no help to decide when to operate Immediate operation is generally indicated If a man drops into the water, struggles and finally disappears, will you try to save him or will you say he will be up again and we will save him then? Palpating with the hand is the only true test of an underlying irritation and inflammation This reveals the rigidity of the muscles of the abdomen over the seat of irritation and points to immediate operation

Dr J E Summers, Jr, Omaha—Diaphragmatic pleurisy is sometimes in the way of diagnosing appendicitis, particularly in children, but I believe it can be very readily recognized In a number of cases, in endeavoring to elicit the physical signs, I have found almost complete absence of the respiratory murmur over the lower part of the right lung In such a case one can say that he has a pleurisy to deal with It is usually in pleuropneumonia that the pleuritic elements largely predominate Dr McCosh did not refer to typhoid fever as a complicating factor in making the diagnosis, the general symptoms are usually more severe than the local ones, but you do get localized symptoms on pressure as in appendicitis, but not so characteristic As to Dr McRae's remarks, I would say that if the difficulty for which the abdomen is opened is complicated by appendicitis the appendix should be removed, otherwise not As to Dr Deaver's paper, I am almost too modest to discuss it on the adverse side I did my first operation for appendicitis nineteen years ago and since that time I have been on all sides of the fence regarding the time for operation In later years I have taught that Deaver is too radical, and statistics will prove that our mortality is unnecessarily high if we follow his advice When the disease is progressing, and I am convinced of the symptoms of perforation, I operate with good results If we operate on the third, fourth or fifth day we lose too many patients, whereas if we do not operate, but go according to the teaching of Dr Ochsner, many more cases recover Statistics in my community show that this is so Since we have stopped following Dr Deaver we have obtained better results I am glad to see that Dr McCosh has become more conservative Perhaps others will follow him in the adoption of the Ochsner treatment It seems foolish for us to discuss Dr Deaver's paper, but maybe he has not yet told us the way to do the operation

Dr F L Hupp, Wheeling, W Va —It is an unfortunate fact, but one which we are obliged to accept, that all cases of appendicitis do not get well One of the factors determining a fatal issue, where there has been a beginning diffuse, septic peritonitis antedating the surgical interference, is a continuance of this process Of the seven cases of this kind that have come under my care in recent years and been operated on, two have died in this way Practically all other deaths in these cases were a result of well known and recognized causes but within the past four weeks there has come to my notice a case of appendicitis which presents a unique feature in these mortality factors, so far as my experience goes A boy of 14 years of age was admitted to my service in the City Hospital of Wheeling, W Va , who had been treated by his family physician for typhoid fever for a period of eleven days prior to admission His symptoms seemed to have been typical up until the tenth day, when there was discovered an induration and localized tenderness in the right iliac region On the day of admission, May 6, under chloroform narcosis the usual incision was made and about an ounce of very offensive pus was removed from the retrocecal region In the washing there escaped a tubular segment of the appendix vermiformis, much resembling a macerated piece of macaroni A suspiciously dark area was detected over the cecum, but because of the profoundly collapsed condition of the patient no further interference was deemed advisable Well directed drainage was established and the patient removed from the table Forty eight hours after the operation the dressing was repeatedly saturated with a dark, offensive, coffee ground fluid, and at times there seemed to be some fresh looking blood with the exudate The drainage strips were removed and there welled from the depths of the wound a quantity of decomposed dark blood clot Collapse and death followed three days after the operation The real interest in this case centers in the autopsy The cecum, buried in a mass of rather firm adhesions was the seat of a gangrenous perforation sufficiently large to admit two fingers No remnant of the appendix was discernible A very extensive extravasation of old decomposed blood was found distending the cecum, ascending colon and part of the ileum Peyer's patches exhibited the typical typhoid lesion and an eroded vessel in the base of one of these ulcers demonstrated the seat of the hemorrhage and the cause of death

Dr. A Jacobi, New York City—I have not operated for anything that looked like appendicitis or perityphlitis for twenty years, so that I certainly have no right to speak of the operation as such Still I have seen a great many cases of appendicitis and have been present at a number of operations What I have seen is a great many cases of sudden onsets with rapid pulse and high temperatures, which when left alone were better prepared for operation at the end of a week, and there are many surgeons of the same opinion I recall a case that I saw recently with several other physicians in which some of us desired an immediate operation A surgeon was called in, who stated that if he operated on the case in its present condition with the high temperature and the state of collapse, the operation might be successful but the patient would die He operated a week afterward and the patient recovered I have seen a number of such cases operated on at the end of a week and they recovered On the other hand we see many cases of appendicitis get well under what is called medical treatment That is not infrequent with children who, though they may have other attacks, still recover and after growing up never have another attack I do not believe that there should be for all cases one and the same rule What I am more interested in is the diagnosis, and that we are told by Dr McCosh, is sometimes very difficult Eight weeks ago I was called to see a child 4 years old who had been ill two days. There was a physician in attendance and two consultants beside myself There were very few symptoms, but appendicitis had been mentioned at first by the family physician None of us was ready to make a diagnosis of appendicitis The child had vomited three or four times a day for two days and there was some diarrhea The tendency among the doctors was to call it gastroenteritis There was very little pain and all that I could elicit was on the left side of the transverse colon. It appeared to me to be a pressure pain, as it was not present fifteen minutes afterward There was no muscular rigidity over the appendix nor any pain when pressure was suddenly discontinued Meltzer's symptom was absent, there was but little tympanites I saw no reason to diagnose appendicitis and one of the famous surgeons of New York was called in and also said that it was not appendicitis and that there was no reason to operate Two days afterward the child died, and the postmortem showed an abscess and many adhesions There are cases in which no diagnosis can be made as Dr McCosh has told us, either by the medical or the surgical man. I have no particular reason for recalling this case except that I have been conscience-stricken all the time and still I do not know how to avoid a mistake when there are no symptoms pointing unmistakably to appendicitis Unfortunately, such doubtful cases do occur

Dr. Henry O Marcy, Boston—It is quite eighteen years since my first operations for appendicitis During this period, both in public and private service, my operations have been too numerous to demand statistical tables, and yet not one of the entire series but has made an easy recovery where the appendix had not ruptured prior to operation Experience is now ample on which to formulate rules for surgical guidance I am not quite ready to say, 'When in doubt, operate" The wise surgeon makes an early diagnosis It often demands heroism to be guided by the fact that the sins of omission are to be judged on the same plane as the sins of commission

Dr William H Wathen, Louisville, Ky—Dr Deaver praises the general surgeon in his work in appendicitis at the expense of the gynecologist, but he fails to tell us that the basic principles of all successful abdominal surgery were evolved from and made eternal in the work of the gynecologist The gynecologist taught the general surgeon the underlying principles that to-day are held sacred in all intraperitoneal surgery, and this encouraged us to efforts in the application of surgical treatment to the diseases of the appendix, gall bladder, bile ducts, stomach, duodenum, pancreas and other abdominal structures It is true that the general surgeon has done much in perfecting a technic in surgery of the appendix and upper abdomen, for which we give him much praise, but this improved mechanism in operating was made possible by the conditions that preceded his advent into the peritoneal cavity, We include in our American Gynecological Society every disease in the abdominal cavity which is treated by the general surgeon Then let the gynecologist and the general surgeon unite in efforts to evolve the best methods in the diagnosis and therapy of diseases in the abdominal cavity, for there is no consensus of opinion on many vital questions, and we have much to learn and much to forget While it is generally agreed that the appendix should be removed if the patient can be operated on before the inflammation has extended to the adjacent peritoneum, and that the operation is also indicated between the attacks, there is no agreement as to what should be done in all acute cases where there is a periappendiceal septic involvement Dr Ochsner treats these cases by stomach lavage, and claims results far better than he had obtained by operation while Dr Deaver claims the reverse in his work, and as these gentlemen have had much experience, this difference of opinion and practice must be carefully considered and logical conclusions accepted I am sure I have had deaths in operations for appendicitis in acute cases where adhesions had formed, and where I opened the abdomen immediately over the infected area, because I could not intelligently separate adhesions and successfully protect the surrounding peritoneum from infection By making the incision to the left and beyond the infected area, splitting the rectus muscle, or opening through the linea alba, we may isolate infection and intelligently treat pathologic conditions In diffuse suppurative peritonitis, in appendicitis, stomach or intestinal perforation, gall bladder rupture and visceral wounds, my experience and observation have taught me that we may expect better results where we avoid the additional peritoneal irritation necessarily resulting from saline irrigation or extensive sponging After thorough irrigation and sponging, much septic matter will remain in the cavity, and the added traumatism to the peritoneum will so impair its resisting powers as to encourage the more rapid multiplication of pathogenic bacteria The mortality will be less if we operate on such cases quickly Do not irrigate, do but little sponging, and drain from the lowest part of the cavity by a large gum tube, thus removing intraperitoneal tension and thereby increasing resistance to further bacterial multiplication and invasion I believe that much of the mortality in these cases is the result of too much irrigation and sponging and insufficient drainage If the infection is virulently streptococcic, the cases will die under any treatment, but otherwise most of them will recover if treated as I have suggested if the operation is not too long delayed

Dr. Ernest Laplace (replying to Dr Wathen)—I stated that where pus extends all over the peritoneum and the inflammation is general, we can not thoroughly cleanse the peritoneum at the time of the operation In these cases only do I advise repeated irrigations by the method I have introduced.

Dr. A J Ochsner, Chicago—I would say that there are two classes of cases of acute appendicitis in which it is sometimes difficult to limit the infection to the vicinity of the appendix because of the absence of a sufficiently large omentum testine follows those cases in which an abscess existed at the time of first operation and in which drainage was used This furnishes a most potent argument in favor of the early operation with removal of the appendix before the extension of the inflammation gives rise to a serofibrinous exudate As I have remarked in a previous paper, "walled-off" is an expression often used by physicians as a term of congratulation, but it also denotes a most fertile condition for a future intestinal obstruction

I find obstruction to follow acute appendicitis in about 1 5 per cent of cases, and to be due, of course, primarily, to bands of adhesions, but also predisposed to by too early and injudicious feeding of the patient The resulting increased peristalsis and general intestinal disturbance cause congestion and swelling of the intestinal wall further narrowing the lumen of the bowel

Fecal fistula may follow cases in which an abscess collection causes pressure necrosis on the bowel, when the cecum is directly involved in a gangrenous process, or where the entire appendix has not been removed While such fistulæ do not directly have great influence in increasing the mortality, yet the operation which must later be undertaken for their repair is by no means devoid of risk

Finally, the great percentage of extensive drainage cases are followed by hernia for which mechanical appliances are of no avail Hernia requires a secondary operation which is more formidable than the primary one

In conclusion, I would again urge on you to advocate the early operation for appendicitis The tendency of many surgeons at the present time to occupy a sort of middle ground should not be imitated by the rising generation I know of successful surgeons who operate immediately when a case reaches the hospital, and yet who formulate and teach their students so many rules for the treatment of appendicitis that a text-book of surgery must be carried around in the medicine case Furthermore, an expression of opinion from members of a surgical association is always of interest to the general practitioner Too often the discussion of a paper is limited to congratulatory remarks, surgeons whose teaching is of infinite value preferring to praise or conciliate a friend rather than to boldly announce their own ideas and practice

DISCUSSION

ON PAPERS BY DRS M'COSH, M'RAE AND DEAVER

Dr Ernest Laplace, Philadelphia—I believe that in every fatal case there was a time when, if the operation had been performed, the patient's life might have been saved, but somebody has been guilty of allowing that moment to pass by I deny that any one can establish the fact that there is pus in the abdominal cavity, that there is a developing case of peritonitis, or can deny the occurrence of fulminating appendicitis If we accept this it follows that by delay we are in a great state of uncertainty as to the future of that patient Taking this for granted, it is useless to deny the necessity of operating during the course of the disease You should do the operation and use common sense, according to the rules on which our knowledge of surgery is founded In every case, when possible, I believe in the dry method of operating I drain and pack, and remove the gauze on the eighth day When peritonitis occurs, one is face to face with another problem Another disease has stepped in, and that is general septicemia The patient may die from general septicemia although the local peritoneum has undergone improvement A patient may die with tetanus even though his thumb has been amputated These cases should no longer exist when a primary operation has been performed I treat general peritonitis on the same common sense principles that I would erysipelas I watch it continuously and treat it locally I flush with sterile water I wish to say that the day has come when we must abandon the saline solution, because it may irritate the inflamed peritoneum I have satisfied myself as to this absolutely by experiments on a man with one good eye and one bad eye The solution irritates the inflamed eye but not the healthy one. I practice repeated irrigations after the operation through tubes above and below and in each lumbar region Leucocytosis is of no help to decide when to operate Immediate operation is generally indicated If a man drops into the water, struggles and finally disappears, will you try to save him or will you say he will be up again and we will save him then? Palpating with the hand is the only true test of an underlying irritation and inflammation This reveals the rigidity of the muscles of the abdomen over the seat of irritation and points to immediate operation

Dr J E Summers, Jr, Omaha—Diaphragmatic pleurisy is sometimes in the way of diagnosing appendicitis, particularly in children, but I believe it can be very readily recognized In a number of cases, in endeavoring to elicit the physical signs I have found almost complete absence of the respiratory murmur over the lower part of the right lung In such a case one can say that he has a pleurisy to deal with It is usually in pleuropneumonia that the pleuritic elements largely predominate Dr McCosh did not refer to typhoid fever as a complicating factor in making the diagnosis, the general symptoms are usually more severe than the local ones, but you do get localized symptoms on pressure as in appendicitis, but not so characteristic As to Dr McRae's remarks, I would say that if the difficulty for which the abdomen is opened is complicated by appendicitis the appendix should be removed, otherwise not As to Dr Deaver's paper, I am almost too modest to discuss it on the adverse side I did my first operation for appendicitis nineteen years ago and since that time I have been on all sides of the fence regarding the time for operation In later years I have taught that Deaver is too radical, and statistics will prove that our mortality is unnecessarily high if we follow his advice When the disease is progressing, and I am convinced of the symptoms of perforation, I operate with good results If we operate on the third, fourth or fifth day we lose too many patients, whereas if we do not operate, but go according to the teaching of Dr Ochsner, many more cases recover Statistics in my community show that this is so Since we have stopped following Dr Deaver we have obtained better results I am glad to see that Dr McCosh has become more conservative Perhaps others will follow him in the adoption of the Ochsner treatment It seems foolish for us to discuss Dr Deaver's paper, but maybe he has not yet told us the way to do the operation

Dr F L Hupp, Wheeling, W Va —It is an unfortunate fact, but one which we are obliged to accept, that all cases of appendicitis do not get well One of the factors determining a fatal issue, where there has been a beginning diffuse, septic peritonitis antedating the surgical interference, is a continuance of this process Of the seven cases of this kind that have come under my care in recent years and been operated on, two have died in this way Practically all other deaths in these cases were a result of well known and recognized causes, but within the past four weeks there has come to my notice a case of appendicitis which presents a unique feature in these mortality factors, so far as my experience goes A boy of 14 years of age was admitted to my service in the City Hospital of Wheeling, W Va, who had been treated by his family physician for typhoid fever for a period of eleven days prior to admission His symptoms seemed to have been typical up until the tenth day, when there was discovered an induration and localized tenderness in the right iliac region On the day of admission, May 6, under chloroform narcosis, the usual incision was made and about an ounce of very offensive pus was removed from the retrocecal region In the washing there escaped a tubular segment of the appendix vermiformis, much resembling a macerated piece of macaroni A suspiciously dark and severe depression Pus retained under pressure is rapidly absorbed, whether it be in the peritoneal cavity or elsewhere, and to stop absorption all that is necessary is to relieve the tension If we have an acute phlegmon of the leg we do not wash it out, sponge it, scrape it, or get our hands or feet into it, we simply relieve the tension by opening it, and we have just that to do in peritoneal infection and in addition close the opening from which the infective material is leaking There should be no washing, no sponging, no handling of the viscera I advise putting a rubber drain down into the vesico-rectal fold and placing the patient in the semi sitting position I am sorry to differ from Dr Laplace, who gets results from washing, while I get them without washing I do not question his results, but I should have to see every detail of his technic and of his treatment before I would consider changing I do not care what the technic is if the results are secured I have operated on every case of general suppurative peritonitis that has come under my charge in the period mentioned with the above results

Dr. Joseph Price, Philadelphia—Dr Murphy tells you “to get in promptly and play the game,’ which is just what you should have done in surgery many years ago and the mortality would have been greatly lessened or *nil* Dr Ochsner's paper in Saratoga has had a very bad influence In Dr Murphy's series of sixteen incised perforations he lost one He would have saved this case if Dr Ochsner had not read or published his paper, and probably favored the delay I read a paper some years ago on general suppurative or septic peritonitis, and the Chairman left the chair in this Section and said he could not let it go unchallenged Dr Deaver does not lose cases that walk the streets without appendicitis Such cases as Dr Ochsner reports in his first series of 500 (borborygmus) none should have died Dr Deaver never loses such cases nor does he operate for borborygmus My mortality in 600 cases was four cases The four deaths and the quite universal custom of drainage was largely due to the very strong influence of Dr Ochsner's paper at Saratoga on the general practitioner The gynecologists have taught you all you know If you want to know anything about drainage come to Philadelphia Many of us have lived through our period of usefulness, beyond the age of [illegible]0 Do not let the youth of the country die in such large numbers A few years ago 400 deaths from appendicitis were recorded in Chicago in one year Since then Chicago has probably lost 1,600 a year from appendicitis If we put the mortality at 100 to the state (very light) we have a death rate in the very future of our population of 5,200 a year No one should ever be permitted to die of appendicitis There is no therapeutics in its management, no starvation, no sweet oil, no icebag—only clean early surgery following the diagnosis which is easily made This sharp discussion reminds me strongly of the old discussions on this subject many years ago Many of us fought the battle all over the land and thought the last word had been said, and rejoiced that the natural history and treatment had been established for all time

Dr. Robert T Morris New York City—Should we remove the appendix when the abdomen is open for some other cause? Our best statistics occur among people who have no occasion for any sort of surgical operation The next best statistics occur among people who require the least amount of surgical work The logical deduction is that the easier we allow a surgical patient to escape the better will be the record Leave the appendix alone until it is infected, and then lose no time in having it inspected That couplet expresses my views There are three chief objections to the plan of removing the appendix when the abdomen is open for some other cause First, it prolongs the other operation Next the patient's resistance factors may not have been called out to meet the little special infection that may occur from opening the lumen of the bowel Third, if the procedure is taught by competent men it will be carried out by some who will manage to get a death rate out of it Dr Deaver speaks about “kindergarten drainage in New York ” It is better than committing taxidermy on your patients but there are many operators in New York who agree with Dr Deaver Some of those who have arrived at the point of making ‘kindergarten drainage have such good statistics that they are accused of removing normal appendices in order to get such results Gauze packing in the peritoneal cavity is a foreign body, and harmful and unnecessary Take ten healthy policemen from the street to day and put half a yard of gauze in the abdomen of each one, and we shall probably lose one or two of them If strong, healthy men can not bear the presence of gauze in the peritoneal cavity how can weak appendicitis patients bear it? Do not commit taxidermy on appendicitis patients Some of us do not use any gauze packing at all in the peritoneal cavity

Dr Mordecai Price, Philadelphia—Within the walls of this room are men who have seen me open 100 cases of general peritonitis and gangrene from appendicitis, and with thorough washing only two or three have died in the state of New Jersey Probably in Dr Ochsner's cases his treatment is all right In the hands of the gentlemen throughout this country it has been anything but satisfactory Appendicitis has no place in our work except for immediate removal I remember the case of a young lady who was almost dead I could find no tumor but a pronounced resisting point, and I diagnosed appendicitis I said I should remove the appendix within the next twenty minutes and did so, when I found it gangrenous beyond repair I remember another case which had been ill for five days There was a pronounced resistance over the appendix and I advised immediate operation The woman had not had a pulse over 80 nor any temperature I operated and found a gangrenous appendix although she had not seemed to be very sick Dr Jacobi asked about diagnosis When you get hold of a patient where you can not tell just exactly what's the matter, and there is a slight resistance over the appendix, take it out

Dr. Deaver—Dr Summers evidently misunderstood me I made the statement that operation should be done in all cases when the patient was seen early I have advised delay in certain cases in the presence of a general septic peritonitis I do not take out the appendix in all cases Dr McCosh advises that we wait until recovery from the attack, but I consider this dangerous practice in certain cases Dr Jacobi, like many medical men, has not the courage to decide that the case belongs to the surgeon Many young doctors never realize the value of palpation There is no doubt but that had the Jacobi case been seen by Dr Ochsner, Dr Price or others, the diagnosis would have been made Better take out a healthy appendix and have the case get well than leave a diseased appendix and let the patient die I could never understand this question of diagnosis How do these distinguished people make such errors? The diagnosis is usually made by my internes and it is rarely necessary for me to walk into the surgical ward to do this If internes can do it surgeons should do better Dr Wathen has referred to the gynecologists They should confine their work to the pelvic cavity If seen early appendicitis should readily be diagnosed As to treatment, there is a great difference of opinion I can not interpret my friend Ochsner's statistics My cerebration may be a little defective. I do not operate on cases with advanced peritonitis of several days' duration that are practically moribund as I stated in my paper Before I came here I looked up my mortality since January 1 I do not like to speak about it here because I do not expect anybody to believe it any more than I should expect to believe others I have operated on 159 acute cases since January 1, on patients who had been ill for from three days to four or five weeks I have evacuated appendiceal pus by the gallon The statistics of these acute cases is 5 per cent plus I am convinced that there is no treatment under the heavens other than the judicious surgical technic that would give you as low a mortality as this in acute cases I do not expect to lose any in the interval operation but when we do it is usually from pneumonia and such exceptions will occur I go Dr Murphy one better He had sixteen cases with one death while I had sixteen with no deaths The class of cases of general peritonitis that I have had recover had only been ill a few hours. I operated on a case of that kind last Saturday The temperature was 104 the abdomen was distended there was muscular rigidity, and when I opened the abdomen I rolled out an inflamed appendix,

from his list as many of the fatal cases as can be possibly eliminated in order that his percentage of cures may be raised[1]

Not only is the mortality of pneumonia appalling, but it is steadily increasing This fact is conclusively proven by the following curves constructed from the statistics of the Massachusetts General Hospital, the Boston City Hospital, the Cincinnati Hospital, the Glasgow Royal Infirmary and the Wiener Allgemeines Krankenhaus The statistics of the United States Army are given as an example of the very uniform death rate which may be shown during a long term of years by some series of cases It is fair to state, however, that the mortality rate of 15 7 per cent shown by this series, 1868-1902, is nearly one-half greater than the 10 8 per cent shown by the cases occurring in this army in the years 1840-1859

The causes of death are the direct effects of pneumococcal activity This fact I desire to emphasize In the vast majority of cases death is due to a profound toxemia, in which case the gross anatomic lesions may be quite insignificant, or they may be of the most extensive and destructive character, or they may be of any intermediate grade, but whatever the extent and character of the demonstrable lesions, the fatal result must be laid to the door of the, as yet, intangible systemic pneumococcus intoxication

Certain noticeable effects follow and are directly due to the introduction into the system of the pneumotoxin it may be in infinitesimal quantity and diluted beyond computation, as, e g the profound chill, the raging fever, the lowered arterial tension, the disturbed balance between constructive and destructive metamorphosis, the interference with the excretion of waste, etc Other pathologic changes may be due to the effects of the pneumotoxin, plus the combined toxic leucomains of tissue waste, etc The measure of these, especially of the first class, will depend on the virulency and special characteristics of the infecting germ, and the intangible and immeasurable general and special resistance offered by the patient This will necessarily vary infinitely in different persons and in the same person at different times, and this brings to the fore those large questions of inherent and acquired relative immunity and susceptibility which can only be mentioned at this time Neither can any attempt be made to analyze the influence of the immediate and more or less remote effects of pneumococcal activity, namely, extent of the hepatization, pleurisy, pericarditis, cardiac thrombosis, meningitis, etc, and of such accidental complications as nephritis, cardiac valvular disease, arterial degenerations, anemias, diabetes, obesity, etc, direct and marked as they must be

---

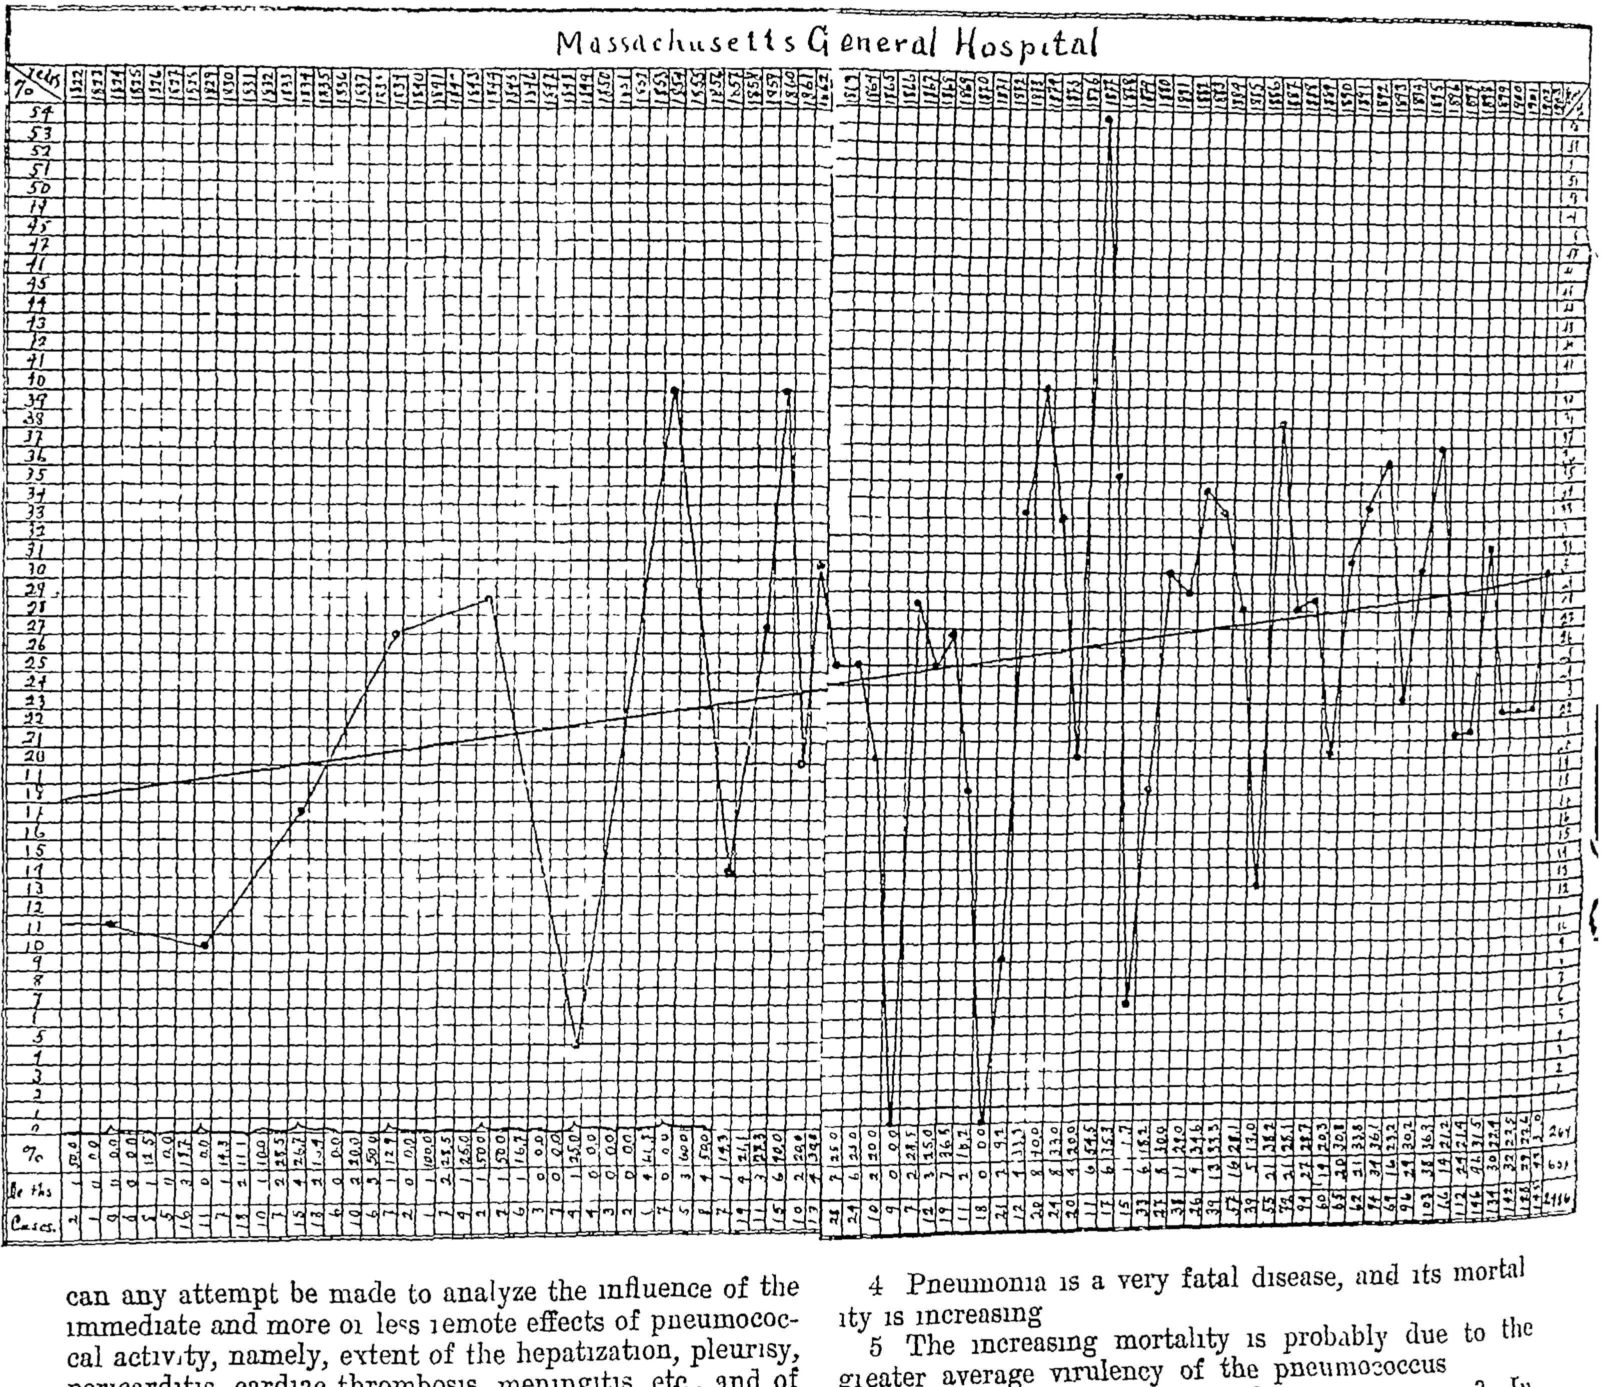
[1] Formerly many writers considered pneumonia a disease of comparatively slight danger Thus Bennett says that the mortality of uncomplicated cases, properly treated should be practically *nil* and this opinion was shared by Barthez Joly D Espine, Waters Wood Hartshorn and others. Trousseau says that generally speaking there is a tendency to spontaneous recovery Flint says that in uncomplicated cases 'the intrinsic tendency is to recovery indeed recovery is not only the rule but the exceptions are exceedingly infrequent. Gerhard affirms that the death rate in private practice should not exceed 2 or 3 per cent. To be sure these opinions were not shared by all the writers of the day as for example Loomis says that a disease in which death occurs in one out of five cases should be classed among the very fatal diseases, and similar views are held by Copland Watson Drake Sturges and others. As a rule the latest editions of the textbooks on practice which are in the hands of the great majority of American medical students estimate very fairly the dangerous character of the disease. Thus Osler says that pneumonia is the most fatal of all acute diseases. Tyson says that it is the most fatal of all infections of adults in temperate climates. Anders says that the death rate in hospitals is about 25 per cent. in private practice about 15 per cent. Thompson places the mortality at 30 per cent for hospital and 8 to 15 per cent. for private practice. Philip Mackenzie West Pye-Smith Fitz Aufrecht and Eichhorst all are aware of the real hazard of the pneumonic attack Strümpell stands alone in his opinion that pneumonia belongs to the benignant infectious diseases '

Time will not permit a consideration of the bearing exercised on the prevalence and mortality of pneumonia by the changing environments of the population as a whole or in its parts—the varying age relations, the prevalence of drunkenness, the therapeutic modifications which have ensued, as well as other important factors, although there can be no question as to their weight as modifying influences I will, therefore, content myself by reiterating the following conclusions

1 Pneumonia is a very prevalent disease, and its prevalence is increasing

2 This increasing prevalence is probably due to the wider diffusion of the more vigorous strains of the pneumococcus, made possible by the increasing commingling of people

3 The pneumococcus is to be found in the upper respiratory passages of a very large proportion of healthy persons, and it is the migration of these ever-present germs into the pulmonary alveoli which causes pneumonia



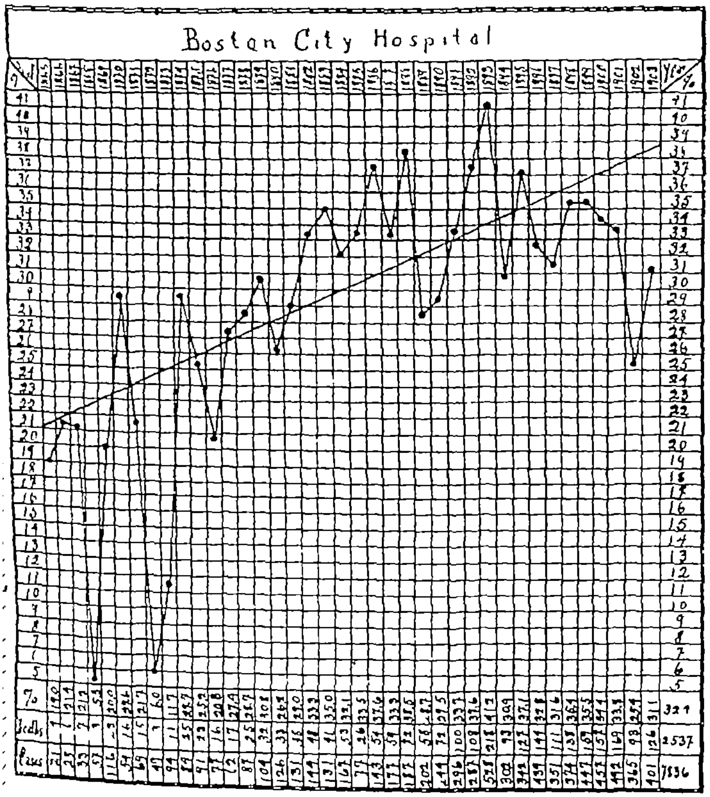
4 Pneumonia is a very fatal disease, and its mortality is increasing

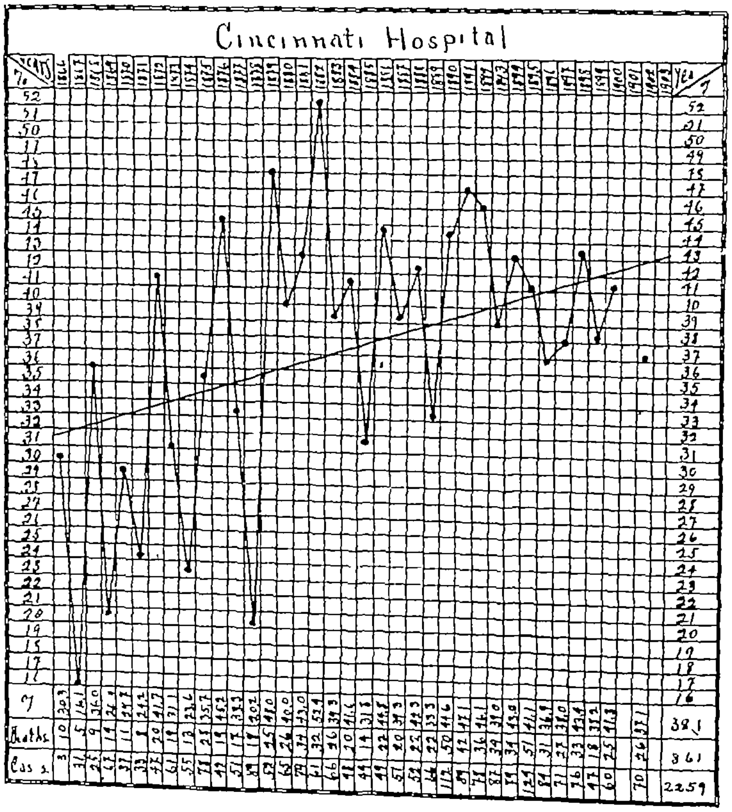
5 The increasing mortality is probably due to the greater average virulency of the pneumococcus

What can we do to prevent and cure pneumonia? In my opinion, we now have the foundation laid, as outlined above, for a reasonable and practicable prophylaxis We are prepared to formulate broad rules, with insistence on some of the details, but the latter will require careful and prolonged study before they can be reduced to that clearness and simplicity which will appeal to every mind and compel acquiescence and compliance I believe, however, that the time is now ripe for a great forward movement along these lines I have certainly failed to feel aright the professional and public pulse if we have not at our hand a populace ready and willing to be instructed in this matter, and to heartily co-operate with us in every reasonable prophylactic measure which we may recommend This is indeed fortunate, for without such assistance all our efforts will go for naught

The following prophylactic measures, the reasons for each of which are obvious, are offered for consideration

1 Pneumonic sputum should be destroyed before it has become dry The sputum which clings to the teeth and lips, and that which may adhere to the fingers and bedding, should be wiped up with moistened cotton, gauze or other cloth and these burned All sputum, although not pneumonic, might well be destroyed In coughing, in the case of the healthy as well as the pneumonic, a cloth, preferably moist, should be held before the mouth in such manner as to prevent the projection into the surrounding air of the fine, insensible, but probably pneumococci bearing spray which follows ordinary coughing The same applies to sneezing and blowing the nose





2 The nostrils, mouth and throat should be kept as clean as possible Cleansing sprays and washes for the nostrils, washes for the mouth and brushing the teeth, gargles and drinks for the throat Permanent occlusions of the nostrils should be removed, while transient ones may well be cared for by the more or less frequent use of a spray of adrenalin solution Honeycombed tonsils and adenoid growths should be removed Taking a drink of water after eating is a habit which should be formed and cultivated Every means should be taken to prevent sleeping with the mouth open

3 The room occupied by a pneumonic patient should be afterward disinfected, as is done after diphtheria and some other infectious diseases Remaining long or unnecessarily in a room occupied by a pneumonic patient should be avoided

4 Respiratory catarrhs, from whatever infection, should be avoided, and if contracted should be relieved as quickly as possible

5 Physical and mental exhaustion, privation, undue exposure to cold and inclement weather, all should be avoided as far as practicable

In the treatment of pneumonia we are, as yet, lacking in a direct antipneumonic remedy—a specific—yet in the management of the pneumonic attack, which must be conservative and symptomatic, certain definite objects should be kept in view

Preliminarily, it may be mentioned that the patient's environment should be the best which is available The nursing should be assiduous and of the highest grade The medical attention should be intelligent, careful, observant and unremitting

At the very beginning of the pneumonic attack the patient should be placed in bed, surrounded by bottles of hot water and given a hypodermic injection of a single small dose of morphia, e g, 1/16 to 1/8 grain He should be allowed to lie quietly until the subsidence of the chill, when the bottles of hot water should be removed If perspiration should be profuse the surface of the body should be dried The bowels should now be opened by an enema of 2 oz Epsom salts, 2 oz glycerin and 12 oz water Later an efficient cathartic should be given

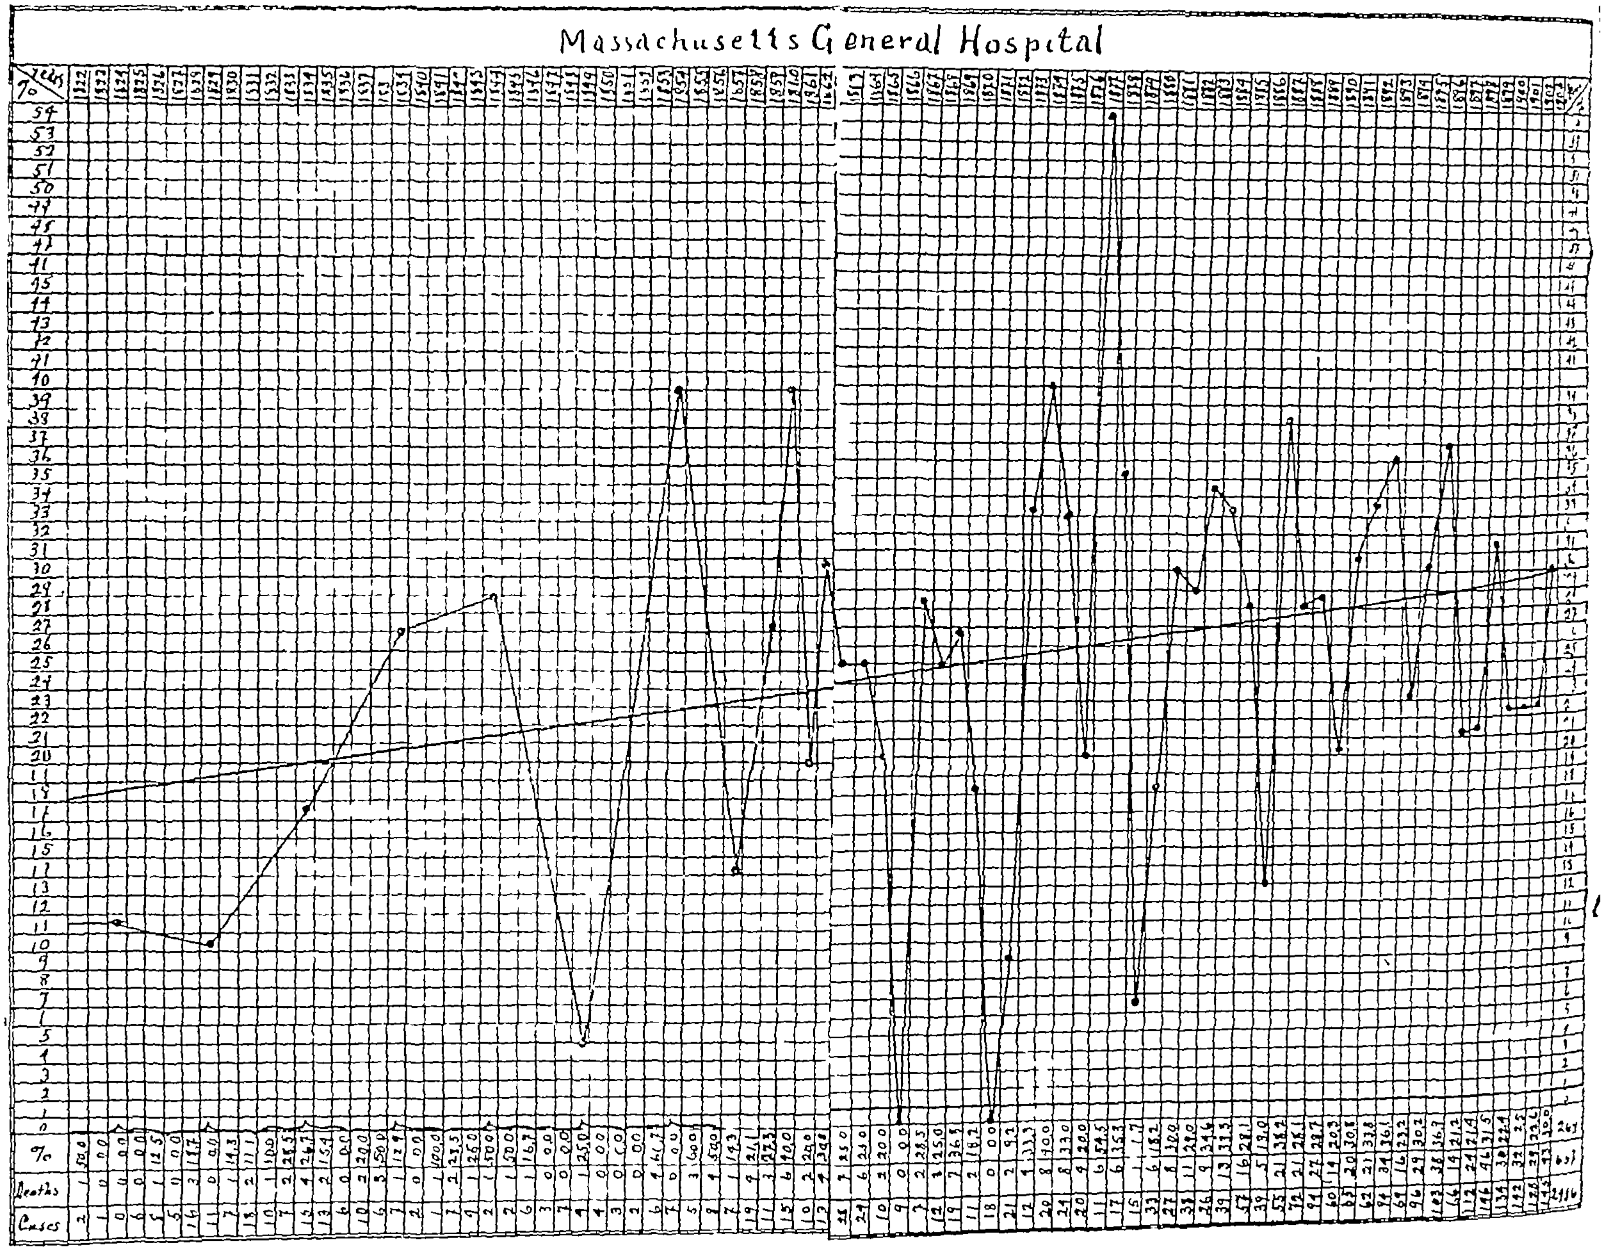
Moot questions arise with surprising promptness The first of these will be that of the management of the reduced arterial tension, which is one of the earliest and most persistent of the symptoms of pneumonia This is probably an efficient provision of nature for setting free and mobilizing an army of defending leucocytes, and protecting the tissues of the body from the irritating and paralyzing effects of the pneumococcal toxins Nevertheless, certain other and most undesirable effects follow, as, e g, the arterial system is underfilled, while the venous system is overfilled with blood, osmosis through the capillary walls is largely suspended the tissues are not nourished and waste material is not removed, the heart, contracting against a greatly reduced resistance, becomes tired or exhausted What shall we do under between constructive and destructive metamorphosis, the interference with the excretion of waste, etc. Other pathologic changes may be due to the effects of the pneumotoxin, plus the *combined toxic leucomains* of tissue waste, etc. The measure of these, especially of the first class, will depend on the virulency and special characteristics of the infecting germ, and the intangible and immeasurable general and special resistance offered by the patient. This will necessarily vary infinitely in different persons and in the same person at different times, and this brings to the fore those large questions of inherent and acquired relative immunity and susceptibility which can only be mentioned at this time. Neither can any attempt be made to analyze the influence of the immediate and more or less remote effects of pneumococcal activity, namely, extent of the hepatization, pleurisy, pericarditis, cardiac thrombosis, meningitis, etc., and of such accidental complications as nephritis, cardiac valvular disease, arterial degenerations, anemias, diabetes, obesity, etc., direct and marked as they must be.

Time will not permit a consideration of the bearing exercised on the prevalence and mortality of pneumonia by the changing environments of the population as a whole or in its parts—the varying age relations, the prevalence of drunkenness, the therapeutic modifications which have ensued, as well as other important factors, although there can be no question as to their weight as modifying influences. I will, therefore, content myself by reiterating the following conclusions:

1. Pneumonia is a very prevalent disease, and its prevalence is increasing.

2. This increasing prevalence is probably due to the wider diffusion of the more vigorous strains of the pneumococcus, made possible by the increasing commingling of people.

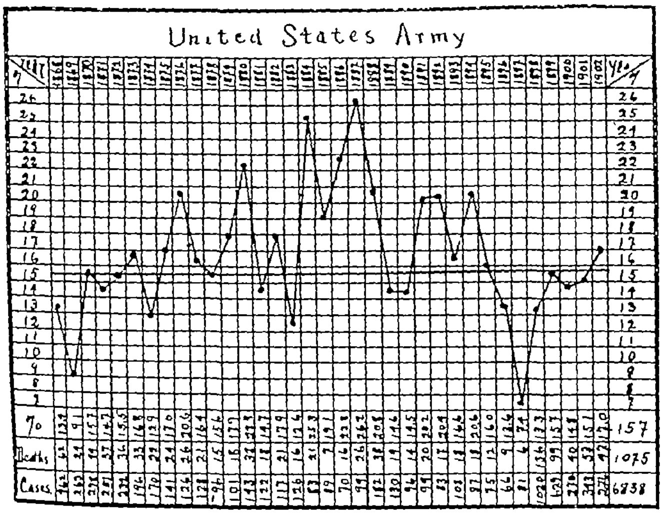
3. The pneumococcus is to be found in the upper respiratory passages of a very large proportion of healthy persons, and it is the migration of these ever-present *germs into the pulmonary alveoli* which causes pneumonia.



4. *Pneumonia is a very fatal disease, and its mortality is increasing.*

5. The *increasing mortality* is *probably due to the greater average virulency of the pneumococcus.*

What can we do to prevent and cure pneumonia? In my opinion, we now have the foundation laid, as outlined above, for a reasonable and *practicable prophylaxis*. We are prepared to formulate broad rules, with insistence on some of the details, but the latter will require careful and prolonged study before they can be *reduced* to that clearness and simplicity which will appeal to every mind and compel acquiescence and compliance. I believe, however, that the time is now ripe for a great forward movement along these lines. I have certainly pear, or, having appeared, subsequently declines The one agent, however, to which we can appeal with a certainty that the heavy burden of profound toxemia will be lightened, is venesection If, under these circumstances, from 8 to 24 ounces of blood is withdrawn, the amount of pneumotoxin in the blood vessels is, initially, reduced from 1/30 to 1/10 If at the same time there is introduced into the system, rapidly, a quantity of water equivalent to the amount of blood withdrawn, the remaining toxins are very appreciably diluted This may be done by the employment of large enemas or by hypodermoclysis of normal salt solution Profound toxemia often manifests itself by high temperature, gradually increasing frequency of the pulse, with lowering tension, restlessness and delirium, or a peculiar clearness of intellect, sallowness or duskiness of the surface, etc, and in these cases I can strongly recommend the free abstraction of blood, with normal salt solution hypodermoclysis Do not, however, await the fullest development of such symptoms, but institute these measures on the very first indications of their appearance In this connection I wish to call particular attention to the advisability of giving fluids very freely throughout the pneumonic attack, for the purpose of continuously washing the blood and thereby ridding the system of as much toxin as possible



The rôle of the chlorids in pneumonia is not well understood However, one of the most remarkable of the pneumonic phenomena is the great diminution or disappearance of the chlorids from the urine in some cases This occurs less frequently and less profoundly than is popularly supposed, yet it is a condition to be considered It is reasonable to infer that the chlorids are required in the blood, in the extra-vascular fluids of the body and in the alveolar exudate for purposes of defense against the pneumococcus or its toxins This is a sufficient reason, in my own opinion and in my practice, for the systematic use of sodium chlorid as a therapeutic agent, and I direct that all foods be well salted, and that saline enemata be given as freely and as frequently as they can be retained

The antipneumococcic sera thus far placed on the market have failed to meet that favor at the hands of clinicians which is quickly and enthusiastically awarded every therapeutic novelty of real value Personally, I have witnessed phenomena following the hypodermic injection of such sera which leads me to believe that they may be made agents of real and beneficent power Analogy leads us to believe that a useful antipneumococcic serum may be produced, and I am hopeful that this will be early accomplished

Fermentative and putrefactive changes in the intestines are not rare and should be accorded special consideration This will usually be prevented by the early catharsis which was recommended, however, throughout the entire attack the functional activity of the gastrointestinal tract should be often and carefully investigated An excess of sulphates or of indican in the urine, the presence of a paretic state of the intestines, with tympanitic distension and an inability to pass flatus, the sudden onset of fetid diarrhea, all should be recognized at once and proper relieving measures applied, as, for example, regulation of the diet, the judicious use of cathartics, the employment of stimulating enemata and the administration of some efficient intestinal antiseptic

Pulmonary edema is an occasional event which, despite its serious nature, may occur early enough to permit of relief Energetic stimulation of the nervous system by strychnia, of the capillaries by adrenalin, and of the heart by a small dose of morphia, are the proper remedies The appearance of profuse, possibly cool, perspiration is an ominous, but not hopeless, symptom Here a prompt appeal to rational therapeutics may be of incalculable value to the patient The condition is probably akin to that of pulmonary edema and requires similar management

Oxygen inhalations meet my approval I begin their use comparatively early and employ them somewhat more freely than is usual Oxygen, used in this manner, I believe to be useful and not at all harmful

It is not my intention to consider the numerous minor, although often eminently useful, measures which are required to meet the various indications for treatment which may arise during the pneumonic attack These defy enumeration and must be applied to meet special case requirements

Whether impending death, in pneumonia, can ever be averted is an interesting and important question. That conditions of great peril may be relieved in some cases I am firmly convinced Among these may be mentioned profound toxemia, circulatory failure, pulmonary edema, intestinal paresis, failure of the nervous reflexes, etc When, however, death has actually begun (the earliest indication of which is an increasing dyspnea, with a rising and falling of the trachea and an unobtrusive clicking noise with each respiration, which persists after coughing), my experience gives no instance of recovery

Finally, the remarkable suddenness with which the changes occur in pneumonia is one of the features which is peculiarly characteristic The patient is stricken suddenly, he improves suddenly, he gets worse suddenly For this reason pneumonic patients should be given the most careful, observant, intelligent and unremitting attention Not only should the physician's visits be frequent, but in not a few cases he should be in constant attendance It is certain that the presence of the physician, ready to act at the moment when unfavorable and portentous conditions arise, increases the patient's chances of recovery, and I am convinced that, in many cases, if such medical attention is not supplied, he is being deprived of some of the resources of our art, and that his chances of recovery are thereby directly lessened I am quite sure that in few positions of peril can the resources of medicine be more humanely employed than in a well-generaled combat with pneumonia

4744 Woodlawn Avenue.

chlorids were absent, the leucocytes 32,800, 20 c c of serum were injected every six hours without any perceptible result, and the patient died

The third, a man of 40, had a mild attack, the serum produced no perceptible effect, and he made an uneventful recovery

The fourth, a man of 37, was admitted with signs of consolidation at the right base On the fourth day 100 c c of serum were injected in the course of sixteen hours The temperature, which had ranged between 103 and 104, steadily fell to 100 The supply of serum was exhausted, and eight hours later the temperature rose again to 103, where it remained for twenty-four hours A new supply was then obtained and 120 c c injected in twelve hours The temperature promptly fell to 99 and remained between 99 and 100 for three days, during which time 300 c c of serum were injected The pulse and respirations also improved Six days later there was a profuse urticarial eruption, with fever and pain in the joints the attack lasting eight days

DISCUSSION

ON PAPERS BY DRS WELLS AND SAILER

DR R C CABOT, Boston—Dr Wells' tables of the cases of pneumonia at the Massachusetts General and Boston City hospitals do not, in my opinion, show any increase in the mortality from this disease during the past twenty years Before that the cases are too few to warrant any conclusions whatever

DR G F JENKINS, Keokuk, Iowa—There are one or two etiologic factors regarding which some information might be given Since 1890 we have had an epidemic of influenza which of itself has not been particularly serious, but as an etiologic factor in croupus pneumonia it is of great importance Influenza affects the mucous membrane making it susceptible to secondary infection by the pneumococcus, and that is why it is more prevalent now than it was fifteen or more years ago Another etiologic factor is the crowding together of people in great cities This crowding lessens the resisting power and at the same time multiplies greatly the centers of pneumococcus infection I think these two factors will explain to some extent the great increase in croupous pneumonia With regard to venesection I think we should go back and study the question a little bit I think the proper use of cold water the proper hygienic surroundings fresh air, diet and venesection when indicated is very important

DR DELANCEY ROCHESTER Buffalo—There are one or two points in which I take issue, particularly the treatment of symptoms as symptoms when the possible treatment of the disease as a whole would overcome the symptoms It would be best to recognize the causes producing the symptoms, and treat them In cases of toxemia, if you get rid of it you will certainly get rid of the symptoms I think it is a great mistake to add, in these cases other poisons in the way of drugs when the patients are already poisoned by the toxins of the disease I approve of bleeding early in sthenic cases, but I disapprove of the administration of opium in the beginning I believe in getting rid of the poisons by the proper use of laxatives, particularly calomel and salts, and by one agent which acts on the skin to produce sweating, namely, hot air by means of a scientifically administered hot mustard foot bath by sweating we can get rid of the poison of pneumonia a great deal better than by the administration of diaphoretic medicines Last year at the New York State Medical Association I reported 210 cases of pneumonia, with 23 deaths, this included all sorts of cases and gave about 11 per cent mortality This is comparatively a very low death rate To relieve the pulmonary edema occurring late in the disease as a result of failure of the right heart, I believe that bleeding is of the utmost value, when in pneumonia the right heart becomes greatly dilated as in the case of a boy of 16 years, whose heart apex was in the axillary line with consolidation of the right lung, with a liver extending one inch below the border of the ribs and with pulsation in the veins of the neck, by withdrawing about 800 c c of blood the pulse can be made to fall from 140 to 120, and the temperature several degrees, and the respirations from 56 to 30, and impending death be thus averted, it is a procedure not to be neglected I think it is a mistake to treat the temperature If you treat the conditions present, the toxemia and then the special conditions as they arise, you can get good results The boy referred to recovered after nineteen days' sickness

DR ROBERT H BABCOCK, Chicago—I have been particularly struck by a statement made in the second paper that a patient died from pulmonary edema seven days after the crisis Pulmonary edema is usually supposed to be due to right heart failure, and the occurrence of the edema seven days after the crisis suggests the possibility of the explanation offered by an Italian experimenter that pulmonary edema is due, not to heart failure, but is a manifestation of pneumococcus infection acting on the pulmonary alveoli He found in cases examined after death evidences of this, since the pneumococci were demonstrable in the alveolar walls It certainly seems in this case that the late pulmonary edema might have been a manifestation of a fresh infection by the pneumococcus If I understood what Dr Wells stated concerning blood pressure, he insisted that it is low from the start I believe that if blood pressure is low at the start it is a contraindication to the administration of veratrum viride, in fact, I protest against the use of cardiac depressants when the blood pressure is already low He stated that the low blood pressure might be an effort on the part of nature to resist infection by setting free leucocytes, that is purely theoretical, but granting the assumption correct, I believe the harm likely to be done by veratrum offsets any benefit due to increased leucocytosis If the blood pressure is low, and grows lower and lower, then as the danger progresses digitalis is the agent par excellence We are all influenced by personal experience, but I think it well to cite what Fraenkel from his great experience finds useful He asserts that the tendency to low blood pressure must be combated, and is offset by the early use of digitalis The form he employs is a fresh infusion injected hypodermatically It is his rule to give four grams of the leaves in 100 c c of water and this amount is injected during every twenty four hours for three days until twelve grams of the leaves have been injected He begins the treatment in all cases seen before the third day, excepting those in which there is so much arteriosclerosis as to contraindicate the use of a drug Fraenkel believes death is the result of toxemia acting on the myocardium, and that, as this danger is enhanced by the low arterial tension, it is absolutely necessary to counteract the tendency to increasing lowness of blood pressure, and personally I believe this is sound reason

DR S SOLIS COHEN, Philadelphia—There are two periods in the clinical history of pneumonia in one or both of which venesection may in many cases be usually employed First in the beginning of the attack to reduce the toxemia Secondly, toward the end of the attack to reduce the overload on the right heart The results obtained in any particular case by venesection, or, indeed, by any other measure, can not, however, be applied to all cases without qualification, the keynote in the treatment of pneumonia, as much as in any disease, is individualization There are so many factors to be considered —the constitution and habits of the patient, the environment the preceding or concomitant complications, etc —that it sometimes becomes a delicate problem to decide what to do in any special case Whenever the indication for interference is not clear there should be no interference However, we may justly draw conclusions from similar features and relations pathologic and therapeutic, repeated in a great number of cases I am satisfied that a goodly quantity of blood may be removed from a patient otherwise in good condition (that is to say, not senile nor terminal infection cases, etc, but cases of frank pneumoccocus infection) at the inception of the attack, diminishing the amount of toxemia and stimulating the reproduction of healthy blood cells This is of benefit independently of the mechanical relief to the obstruction of the circulation in the lung Late in the disease the indication is purely mechanical When blood is removed under the first condition it is well to follow with saline infusion into the vein or under the skin—not too much, not too fast, but in the second condition saline infusion is not well given, because it does not seem reasonable to take blood to relieve the heart and then to add the same quantity of another fluid to embarrass the heart as much as before There is a qualification to this, however, and that is in cases in which the blood is very thick and runs sluggishly from the open vein Saline infusion will dilute it, and the respective quantities may be adjusted with skill Temperature in itself, unless excessive or very low, offers no indication for treatment I have learned to look on cases having temperatures of 103 104 or even 105 degrees F as being—other things equal—more favorable than those cases having a temperature of 100 to 101 degrees The vital reaction is better and the temperature seems to be an indication of this vital reaction Fenwick's statistics point in this direction too, and I was recently reminded on looking over my student notes of DaCosta's lectures that he had taught the same thing The matter is important because many patients are killed by the by effects of antipyretic drugs needless under any circumstances As to veratrum viride, it should be remembered that many drugs are used concerning which it may be said that their physiologic action as laid down in the text books seems to have little bearing on their effect as observed at the bedside I have seen some cases benefited by veratrum viride given early and stopped soon and I know not why Certainly the benefit has not been due to depression of the heart Dr Babcock has well said that this would be a counter indication Perhaps there may be something in the complex chemistry of infections and drugs and body cells and fluids, of toxins and antitoxins, amboceptors and complements which may hereafter explain its action For the present it has distinct empirical value used judiciously—that is before consolidation and for prompt effect using the pulse as an index diminishing the dose as the pulse falls and withdrawing the drug as soon as the pulse reaches 60 or 70 beats in the minute, or otherwise shows that the physiologic effect of veratrum has been attained This I repeat is an index only

Dr. Edward F Wells—In a twenty minutes' paper on pneumonia one can barely indicate a few of the general principles and can not go into a discussion of any of these features systematically In answer to Dr Cabot I stated explicitly that the very first effect of pneumonia on the system was a reduction of the arterial tension there is no doubt about this Within a few minutes of the onset of the pneumonic chill this reduction appears If this is an effort of nature to protect the system from the initial shock of a pneumococcus poison the question arises whether we should or should not assist nature, and I believe that, early, we should do so In view of this I have taught that veratrum viride, given early in these cases seems to offer a further protection from the violence of the initial shock Empirically we know that veratrum viride will reduce the frequency of the pulse and this without raising the arterial tension On the contrary the capillaries are still further dilated I most emphatically disagree with Dr Cohen as to the advantage of high temperature in this disease One hundred and sixty years ago it was stated by Cleghorn who practiced scientific medicine in the island of Minorica, that in pneumonia, in ordinary cases, the temperature in the afternoon reached 102 degrees F with a favorable prognosis, but in severe cases and with a bad prognosis it reached 104 degrees This statement applies to pneumonia to day as it did in the days of this great clinician I wish to set myself right regarding the use of opium I do not think any one appreciates more than I the disadvantages and dangers of the improper use of opium in pneumonia but because it may be improperly used is no reason why it should not be used intelligently, properly and beneficently I stated that in the beginning of the attack, during the course of the chill that 1/16 or ¼ of a grain of morphin given hyperdermatically, will quiet and soothe the patient and be very beneficial Also late in the disease, similar small doses of morphin, especially in those dangerous conditions accompanied by profuse perspiration and pulmonary edema small doses of morphin will stimulate the heart as nothing else can, and sometimes snatch victory from apparently certain disaster With regard to blood letting, from first to last, my only reason is to remove more or less of the toxins and I am quite satisfied that this is the keynote to the situation Occasionally one may bleed for the relief of an over distended right heart, but I always desire to anticipate that event if by the exercise of foresight and discretion it is possible to do so

Dr Joseph Sailer—In pneumonia I have invariably found the blood pressure to be low If very low I regard the prognosis as unfavorable In another series of cases I hope to employ the anti pneumococcic serum intravenously, chiefly because certain other serums, particularly the anti plague serum, seem to be more effective when introduced into the circulation than when introduced beneath the skin

OLD UNREDUCED DISLOCATIONS *

DE FOREST WILLARD

Professor Orthopedic Surgery, University of Pennsylvania Surgeon Presbyterian Hospital

PHILADELPHIA

The term, old unreduced dislocations, is here used to cover cases where the joint surfaces remain luxated for a month or more after the accident The delay in effecting reduction may have been due either to non-recognition of the condition or to the failure of the original manipulative replacement efforts The designation "irreducible" is a misnomer since a joint incapable of reduction by one method may be reducible by another procedure

DIAGNOSIS

The chief element in the prevention of this condition lies in immediate diagnosis at a time when reduction is easy, old dislocations exist because of faulty diagnosis With ordinary anatomic and surgical knowledge, with anesthesia and the Rontgen ray, primary diagnosis is usually a simple matter Whenever uncertainty exists in regard to an injury near a joint, anesthesia should be the rule, since without its employment the pain and swelling often render accurate diagnosis impossible Diagnosis once established, the treatment follows as a natural sequence If manipulative efforts fail, operative measures should be at once instituted The greatest difficulty will, of course, be, encountered in dislocations associated with neighboring fractures, especially in the shoulder region, while the cases most likely to be overlooked are those complicated by severe injuries of other portions of the body

In old dislocations of the shoulder, the body should be stripped to the waist and examined sitting and standing In fracture of the head of the humerus, or of the neck of the scapula, or a separation of an epiphysis, the elbow can be brought easily to the side of the body, and mobility is the rule instead of fixation In all old hip luxations the patient should be naked and examined in both the recumbent and standing posture By this method many errors will be avoided By comparison with its fellow, the loss of normal movements, difference in contour, altered relation of bones and restricted motion will be noted

Pathologic dislocations from hip disease, congenital dislocations, coxa vara, and sliding up of the trochanter after fracture of the neck, should be carefully differentiated Not infrequently I have been obliged in consultation to restrain attempts at reduction in cases both of hip disease and of neck fracture, which had been incorrectly diagnosed as luxations.

COMPLICATIONS

Complications and obstacles preventing reduction are: Inflammatory adhesions and deposits causing partial narrowing of the hole in the capsule, lacerations of muscles and tendons, filling up of the socket by torn muscle or fibrous deposit, fracture of the rim, with bony projections, fragments of fractured bone, a portion of capsule pushed back into the socket, and lastly, the anatomic and surgical ignorance of the surgeon. In dislocations of either shoulder or hip, fractures of the rim are not at all uncommon; the fragments may be found in the socket, or more frequently in the neighborhood, giving rise to osteophytes, which interfere most seriously with reduction, even after open incision. Such an osteophyte was the cause of a fatal result in the hands of Dr. Allis and myself, in which instance the external iliac vein was torn over a sharp cockspur bony point during manipulation of an old hip dislocation.

ACCIDENTS DURING MANIPULATIONS

I shall never forget the suddenness with which a patient suddenly collapsed while I was assisting the late Professor Agnew, more than thirty years ago. In the midst of manipulations for reduction of a shoulder dislocation of six weeks' standing, a sudden ballooning of all the tissues about the axilla occurred, the patient became pulseless and apparently died, respiration ceased and the radial pulse disappeared. Instantaneous thumb pressure on the right subclavian artery arrested the current through an apparently ruptured axillary artery, and by the prompt application of restoratives the patient survived. The enormous hematoma that formed was afterward believed to have been produced by the tearing of the axillary vein. When the pulse returned at the wrist the tumor did not pulsate.

In Agnew's case only manipulations were employed, but in former days, when pulley traction was much more commonly used than at the present time, it was not remarkable that these accidents were common. Guerin tore off an entire arm. Bell tore the axillary structures to such an extent that immediate amputation was necessary. In other cases, gangrene has occurred, followed by either death or amputation. Gibson in 1823, in accordance with the practice of that day, after a week's depletion of blood letting, tartar emetic, etc., subjected the man to pulley extension and counter extension for half an hour, then manipulations were practiced for one and three-quarters of an hour more, one of the procedures being to hang the patient by the axilla over a door. As this was in preanesthetic days, and as the surgeon was obliged on the following morning to tie the subclavian for a pulsating tumor in the axilla, it is rather strange that the patient lived until the eighth day, with the arm in a state of incipient gangrene. The artery was found to have been firmly attached to the head of the bone and capsule.

Lister in 1873, in an old forward dislocation, ruptured the axillary artery with pulley traction by tearing a fibrous band attached to the coracoid and humerus. He tied the artery through an axillary incision and resected the head, but the patient died on the following day.

In twenty-four cases of injury to the axillary vessels during reduction manipulations collected by me[1] fifteen terminated fatally, the result in two cases was uncertain, the axillary nerves were lacerated in one case, in another the brachial plexus was torn from the spinal column. Michans tore off both the median nerve and the brachial artery in reducing a luxation of the elbow, but saved the case by amputation. In the reduction of a posterior dislocation of the head of the femur, the sciatic nerve has been hooked up and carried forward in front of the neck of the femur, with great resultant tension and pain, flexion of the hip and disability.

OPERATIVE METHODS

1. Manipulation and traction. 2. Continuous extension and counter-extension. 3. Arthrotomy, with section of all tissues interfering with reduction. 4. Resection, with replacement, when possible. 5. Subcutaneous incision of capsule or of surrounding tissues, a procedure usually uncertain and dangerous.

Manipulation and Traction.—In former times the resistance of the muscles was considered to be the chief element in the prevention of reduction, consequently extreme force by pulleys was employed, even to the tearing away of the limb. At the present time, recognizing that the muscles are only one of many obstacles involved, intelligent manipulation is considered of the first importance. An extreme degree of force should be avoided lest serious injury result. Full anesthesia should be secured and moderate manipulative and traction efforts instituted. These will vary with each joint involved, in accordance with the usual methods pursued in primary cases, being varied to suit the position of the bone, the present condition as shown by palpation, the skiagraph, etc. Hand movements are, as a rule, much safer than instrumental.

Shoulder.—The manipulative efforts at the shoulder for the reduction of an old dislocation will vary but little from the ordinary ones employed in recent reduction, save that great caution must be observed in the preliminary breaking up of adhesions. Serious accidents, as already enumerated, or fractures may readily be produced by undue force. The indications are: to fix the scapula, apply traction, adduction, external rotation, pressure on head, adduction, flexion, internal rotation.

The old method of upward traction was a most dangerous one, as it put great tension on the axillary tissues; outward traction is less risky, but should be employed *with caution.*

Reduction efforts rarely succeed four months after the luxation.

Hip.—An old hip-joint dislocation is a most formidable condition to encounter, and, next to the shoulder, this joint is the one most liable to be involved; it is also an injury most frequently undiagnosed, as the condition of fracture or of dislocation is often masked or overlooked when anesthesia has been carelessly omitted at the time of the original injury.

I recall a case that occurred twenty-five years ago, in which the man, three months after a heavy fall of earth compressing his body, was discovered to have a dorsal dislocation of the left hip. Under ether I readily reduced this and placed it in the acetabulum with a distinct thud, and with the immediate resumption of the normal position of the leg. When comparison, however, was made with the right leg, it was discovered that the leg which had just been reduced was shorter than the one of the opposite side. This condition was very puzzling, until it was seen that the right leg was not only longer, but was also slightly everted, and that there was a fullness in the region of the thyroid foramen, thus showing that there had been a forward simultaneous dislocation of the opposite hip, both legs having evidently been forced in the same direction All efforts to reduce this failed, although, with the assistance of Dr Allis, I applied all the then known methods of manipulation, leverage, traction, etc The head could be carried to the position of dorsal dislocation, but could never be placed in the acetabulum The fact that the left acetabulum had not been filled up through the three months, and that the rent in the capsule had not united, proved that other complications existed which prevented reduction of the right hip What these complications were, of course, we could not determine, as at that time neither Allis nor myself was bold enough to cut down on the joint Ten years later the man was doing hard laboring work

---

[1] 1. Phila. Med. Times, Aug. 16, 1873.

Allis,[2] who has given most thorough experimental and practical work to hip dislocations, says that the greatest injury to the capsule is confined to the lower two-thirds, and that the upper thickened portion of the capsule, known as the Y ligament, is rarely lacerated, which accounts for its great service in restoration The strong upper rim of the acetabulum, the surrounding muscles and the dense capsule, are all important elements in the prevention of a luxation

A careful consideration, therefore, is necessary as to the probable character and direction of the force, whether a sudden blow or a slowly crushing power has been exerted The *x*-ray is here most useful in determining the extent of the fractures and bony complications

Allis' fundamental law is that a dislocated joint should be restored through steps in the reverse order of the displacement, consequently his manipulative reduction is based on the knowledge that the lower portion of the capsule is the one torn and that the head of the bone in dorsal dislocation, therefore, needs to be elevated into place He first fastens the pelvis firmly to the floor by inserting into the wooden flooring three hooks—strong opened screw eyes—one near the perineum, and one on either side opposite the crest of the ilium To these hooks the pelvis is firmly bandaged over towel pads To avoid interference in the groins from the bandage, a flat metal cross, with its four ends curved on themselves sufficiently to hold the strips of the bandage, is placed above the pubis To-and-fro turns of the bandage are then made from these hooks to the screw hooks in the floor The femoral head is drawn downward by traction, then the flexed knee is lifted over the flexed arm of the surgeon until the head of the femur is brought opposite the acetabulum, if it catches on the rim, the surgeon steps across the opposite limb, carrying the knee with him into extreme adduction, while traction is still made toward the ceiling, and an assistant's hand is employed to lift the head into the socket Reduction is usually accomplished with an audible snap If it does not occur the knee is then carried across the body to a state of abduction while steady, simultaneous upward traction is employed To increase the surgeon's tractile power perforated iron bars are securely fixed with wet bandages to the sides of the lower half of the thigh A rod connecting these bars makes an excellent handle for the surgeon in his traction and manipulation efforts Fix pelvis flex thigh, turn leg and heel out lift press on head turn leg in, extend

Second or indirect method, employing the Y ligament of Bigelow as a fulcrum When the head has been lifted as already described to a position just below the acetabulum, carry the knee with the leg flexed directly downward in extension, the Y ligament will thus be made tense and the head will be lifted into the socket Bigelow's manipulations are flexion, abduction, eversion

For a thyroid dislocation the reverse manipulations may be practiced, still following the law of reversed order, or the head may be thrown into the dorsal position and then reduced In the forward dislocation first flex, abduct and make traction outward, then an assistant presses on the head during adduction and traction Forward dislocation, second method, utilizing the Y ligament, flex, abduct, carrying the knee obliquely inward and downward, then rotate outward, not circumduction, lest the sciatic nerve be hooked up

Bigelow's manipulations for thyroid dislocation are flexion, adduction, inversion, lifting, circumduction

Continuous Extension and Counter-extension —After failure of reduction by manipulation, a very useful adjuvant, especially for the lower extremities, is the application of continued weight and pulley extension in bed for a week or more, so as to relax and quiet muscular action At the end of this time, under thorough relaxation by ether, manipulative efforts may be successful, although failure has occurred at the first attempt

In the upper extremity it is much more difficult to apply continuous extension satisfactorily, even with air pads in the axilla and Stimson's couch with its perforation for the arm

Arthrotomy and Excision —When manipulations fail, the question of open operation becomes a serious matter, especially at the hips The tissues surrounding the joint have not only been originally injured, but have also been subjected to repeated traumatisms during the several efforts at reduction Their resistive power to infection has consequently been greatly lowered, and septic influences easily prevail, as is well instanced in the following case

A man, 28 years of age, with an eight month old dorsal dislocation of the hip that had resisted eight attempts at reduction by as many different surgeons, applied to me for relief The hip was immovable and useless A carefully planned and systematic effort at reduction was made by myself, assisted by Dr Allis, but without avail At the earnest solicitation of the man I consented to operate An incision was made over the trochanter, head and neck in the line of the gluteal muscles, separating the fibers, the tissues were cut away and the capsule opened, but the acetabulum could not be reached An anterior incision was then made in the triangle formed by the tensor vaginæ femoris and the sartorius The head of the sartorius and the long head of the rectus were cut away, the psoas was also cut from the lesser trochanter, the capsule opened strong traction applied, the acetabulum was found filled to the level with fibrous tissue almost as tough as tendon This was cut away with gouge and spud, and a large quantity of thickened tissue was cleaned from the head, which was even then reduced with great difficulty The cushion in the acetabulum still prevented the head from sinking more than one half into the cavity, the bone was, therefore, redislocated and the acetabulum absolutely cleared, at last the head remained easily in its socket, thorough drainage with rubber and gauze was introduced and the limb fixed with plaster of paris, slightly abducted and everted, and nearly in line with the body The hemorrhage was considerable, but no ligatures were required after clamp hemostasis The man vomited persistently from the time of operation, and died a week later from septic endocarditis The operation was long and severe, the chances for infection were numerous

Dr Thomson fractured the femur in an attempt to reduce an old dislocation of the hip He very wisely opened the joint, reduced the dislocation and the fracture, and retained the latter in position with a silver nail, thereby securing a good result

---

[2] Dislocations of the Hip Cross Prize Essay Phil 1896 Octavo p 167

Shoulder The necessity for operative relief will depend largely on the amount of disability and the extent of the pain, the latter being caused by pressure on the nerves and vessels

In a two-month-old subcoracoid dislocation of the shoulder, after failure of manipulative methods, and finding the head thoroughly fixed, I made an incision in the pectorodeltoid groove and resected a portion of the capsule and of the spinati muscles As the luxation still refused to yield a second incision was made about the middle of the deltoid, separating the fibers, and after thoroughly dividing the tissues the head was at last successfully placed in the glenoid cavity The capsule was so greatly injured that its remnants were stitched with catgut to the acromion, the arm was fastened across the chest with a plaster-of-paris bandage, and, after two weeks, gentle passive movements were instituted, with good recovery of motion but with slight loss of abduction and elevation

In a shoulder joint that was dislocated fifteen years previously through a football injury, and where the head of the bone slid back and forth on the anterior ledge of the glenoid, with some eighteen subsequent luxations inflammatory swellings and great disability, I made one incision in front of the deltoid and another through the center of the muscle, separating its fibers The outer portion of the capsule had evidently been torn away at the time of the original injury, and the inner portion had been subsequently elongated and stretched After replacing the bone the external portion of the capsule was stitched to the acromion and the anterior capsule folded and fastened with a chromicized catgut The arm was held for several weeks in front of the thorax until good union had been secured, after which forward movements were especially encouraged, and a firm joint secured [3]

The best access may be obtained to this region and the least injury done by cutting just posterior to the cephalic vein, in the groove between the deltoid and the pectoral, this gives excellent access to the head The axillary incision, while more dangerous, is sometimes necessary when the adhesions between the head of the bone, arteries, veins and nerves are dense, and is also an excellent incision for resection, although through it the glenoid is less easily reached If incision is made over the middle of the deltoid the fibers should be separated as much as possible, not divided, so as to avoid loss of abduction and elevation The posterior incision, which starts beneath the acromion, is most liable to injure the circumflex nerve (which runs just below the acromial ridge), thus cutting off a large portion of the innervation of the deltoid It affords easy access to the glenoid, but not to the head Even with the anterior incision there will be some atrophy of the internal fibers of the deltoid, but this loss is partially compensated by the pectoral The old operation of cutting off the attachment of the deltoid is a bad one If the biceps tendon is torn or cut, it should be restitched In excisions it is better to take away too much rather than too little Hemorrhage is greatly lessened by closely hugging the bone with bone gouge or chisel It is sometimes necessary to divide the tendons of the infraspinatus and supraspinatus, the long head of the biceps, subscapularis and teres minor After freeing the tissues about the head and neck of femur or humerus, I have sometimes had the greatest difficulty in replacement and have been obliged to divide all the tissues most freely In some cases traction on the head may be made through the incision by placing a curved bone elevator or strong wire about the head, by using a lever, or by drilling the bone and inserting strong steel hooks When the glenoid cavity is filled with a tough cicatricial fibrous mass, the socket must be cleared with gouge and knife In the young, great care should be taken not to injure the epiphysis, and resection should not be employed except under special circumstances The natural accommodative mobility of the scapula must be taken into account, and the amount of adhesions The subsequent fixation and pain depend largely on the original injury and the position of the head In resections the keyhole saw or the heavy chain saw is advisable Owing to the liability of breakage, I have had a chain saw made from an old écraseur When old dislocation and fracture coexist, the question of manipulation or arthrotomy or excision is a serious one The broken fragment may have united to the bone in bad position, or it may have become thoroughly adherent to surrounding tissues, or it may be entirely disconnected Fragments may be nailed or wired in position Resection of the head of humerus or femur, though often necessary in these cases, should not be undertaken as a positive rule, since a completely reduced upper joint fragment can sometimes be treated the same as an ordinary fracture and a fairly useful joint secured In cases of doubt, an excision may be deferred in old persons until the amount of pain and disability is definitely ascertained, yet a resected shoulder joint, provided the muscles are not too seriously injured, often gives a more useful arm than the stiff ankylosed one so often secured by the forcible reduction of an old injury Pressure of broken fragments on the axillary vessels and nerves usually gives great pain and demands resection In one of my cases, however, where both dislocation and fracture existed, the aged man was so far advanced with locomotor ataxia that he was practically helpless, and lived several years without any serious inconvenience from the presence of the head in the axilla In other cases, however, the pain is extreme, in others the inflammatory adhesions fasten the tissues in a mass which will not only resist attempts at manipulative reduction, but even persist in spite of open incision Fractures of the shaft of the humerus and of the femur are not uncommon during efforts at reduction

It is extremely important that every aseptic precaution be taken, as disturbance of tissues already below the normal resistive point is prone to give septic results Drainage either by rubber tube or gauze is necessary on account of the severity and length of the operation

Arthroplasty —I have tried a number of methods to prevent the union of joint surfaces, but nature, while sometimes tolerating a foreign substance usually rebels against its continued presence Gold or silver foil is less irritating than rubber tissue The best method is, when possible, to turn in a flap of fascia or connective tissue

Results —Souchon[4] gives, in his admirable compilation, the histories of 133 operative cases of old shoulder dislocation, with their results, accompanied by a complete bibliography He gives the deaths immediately following the operation as 13 per cent, with an additional 10 per cent subsequently, the chief causes being gangrene, hemorrhage, sepsis and pneumonia Of the collected cases about 27 per cent suppurated Naturally, sepsis was much more frequent previous to 1885 A good result, however, has, according to statistics, been secured in over 50 per cent of cases

[3] Burrell s operation for this condition of habitual dislocation is an excellent one Trans Amer Surg Asso, vol xv, p 293

[4] Operation of Irreducible Dislocation of the Shoulder Joint, Trans Amer Surg Asso 1897 octavo, p 138

Reerink gives the fatality of shoulder excision in 47 operative cases, 14 became infected and 8 died of sepsis and other causes

Elbow A dislocation of the elbow sometimes remains undiagnosed and becomes fixed in its malposition In a case of four months' standing (Fig 1) after the first failure at reduction I applied extension for a week The woman was pregnant at the time, and the method gave so much pain and annoyance that after the second unsuccessful attempt at reduction I resected the condyles of the humerus through two lateral incisions (in preference to the posterior triceps cut), brought the ulna into position and secured a useful movable joint A letter received last week states that the fetus was carried to full term, and that the elbow movements are nearly perfect, although strength is impaired

Head of the Radius An old dislocation of this joint is often difficult to replace, but extension, strong pressure and rotation will sometimes accomplish it If unsuccessful, the joint should be opened, replaced and stitched or resected

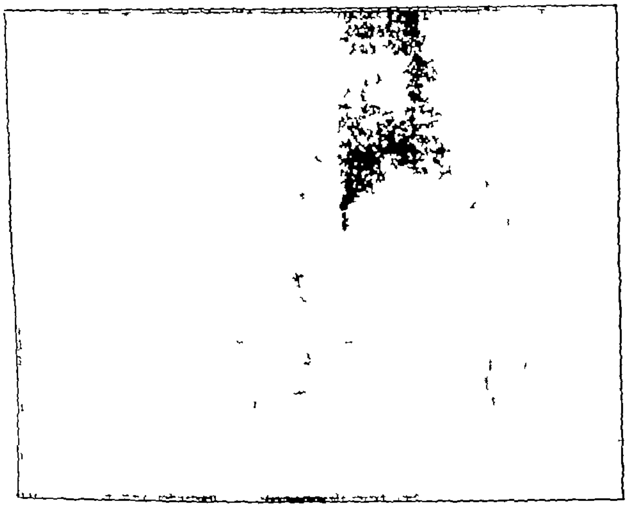

Fig 1—Lateral dislocation of elbow four months duration

Clavicle In an old dislocation of the outer end of the clavicle, Hopkins was able to hold it firmly in place by carrying an X-shaped suture of silkworm through two drill holes in each bone, silver wire would answer the same purpose, or a firm nail could be used

Jaw In a three-month-old dislocation of the jaw Mixter applied lever extension with the fulcrum opposite the molars, and after forty-five minutes was able to reduce the dislocation

Thumb In old dislocations of the phalanges, where the head of the bone has passed between the tendons, these dense structures often resist all efforts at replacement and open incision is imperative

AFTER-TREATMENT

Passive movement should be instituted very early after reduction, and after operation in all old luxations Electricity, massage, voluntary and involuntary muscular movements, gymnastics and other measures for the restoration of function must be continued for a long time

CONCLUSIONS

1 Early immediate diagnosis is the most important element in preventing the existence of old unreduced dislocation With ether, the *x*-ray and anatomic and surgical knowledge, a recent displacement ought always to be discovered by the surgeon Immediate reduction by manipulation or open operation should follow

2 An old, unrecognized dislocation should be carefully examined under the *x*-ray and ether to discover the extent of adhesions and the possibility of effecting reduction without extreme measures The manipulations to be practiced are practically the same as those employed in recent luxations but greater caution is necessary Failing in these, continuous extension in bed should be practiced for a week, the second attempt, without the application of extreme force, should then be made, the permission of the patient having been previously obtained to permit of open operation, if deemed necessary

3 Open section should include the division of all muscular tendinous, capsular and bony obstacles to reduction When the socket is filled up with dense fibrous tissue such tissue should be excavated, and the head of the bone placed *in situ*

4 Partial or complete excision of the head and of fragments in case of fracture will frequently be necessitated

5 In cases that have existed more than a year, or where the original injury has been extreme, operation should be avoided unless pressure on nerves or blood vessels is seriously impairing the usefulness of the limb or giving pain, but resection should be practiced in bad late cases, with pain and serious nerve symptoms

6 Sepsis is frequent on account of the severity and length of the operation, and especially by reason of the non-resistive ability of the tissues due to the original injury and to repeated traumatisms from manipulative efforts

7 Pain, disability, age and occupation are the most important conditions in arriving at a decision concerning operation When a limb is useful in its new position, gives no pain or difficulty it should be let alone

8 In the after-treatment, muscular gymnastics, electricity, voluntary and involuntary muscular movements and massage are very important measures and should be persistently employed These manipulations require both patience and pluck on the part of the patient

DISCUSSION

Dr A F Jonas, *Omaha*—My personal experience with old dislocation of the joint is limited almost entirely to the shoulder joint, of which two years ago I reported seven cases Of these, six were operated on and one was not One feature of the operative cases was common to all, and that was the contraction of the capsule The first of the series had remained unreduced for three or four months I began to use Kocher's manipulations, and it became reduced by this method The remaining seven cases were reduced by manipulation The structures which opposed reduction varied with each case In one the coracoid process was broken off and had become adherent *in its* new locality Before it could be replaced it was necessary to remove this broken off portion of the coracoid In another case the long tendon of the biceps stood in the way of reduction, but the contracted capsules of the joints gave most trouble Extirpation was necessary in one of the cases Usually the head of the bone was replaced, but in most of the cases we injured the circumflex nerve, owing to the amount of manipulation We could not always locate it, and in most of the cases we had atrophy of the deltoid muscle Strangely, the mobility of the scapula is such that all of these cases were able to perform the duties to which they had been accustomed There were no deaths, and the recoveries were all by primary union So far as adhesions to other joints are concerned I only recall one of dislocation at the head of the radius which had existed for four or five months I had to cut down on the head of the radius to replace it in its normal position

Dr C E Thomson, Scranton, Pa —I will report one case of dislocation of the hip My patient, a miner, was injured last June by being run over by a mine car The leg was lacerated and was amputated five weeks later four inches below the knee At that time the dislocation of the hip remained undiscovered He came to me last February, when I attempted to reduce his old dislocation I used the Allis method of fixation of the hip While Dr Allis recommended it so enthusiastically for experimental work on the cadaver, he was a little chary about recommending it on the living patient We used it most energetically, without any injury to the patient further than slight excoriations After the most energetic manipulations we failed to reduce the dislocation Having failed by the Allis method, we tried the Kocher method, with disastrous results Notwithstanding that we had but a stump to manipulate, we broke the bone between the trochanters—an oblique fracture—by the Kocher method Ten days later we renewed the attack and succeeded in reducing the dislocation with long, blunt hooks similar to those used for handling meat We used anterior and posterior incisions similar to Hoffa, and the patient made a good recovery The fracture was held in place by a specially devised nail Union has taken place in the fracture and we hope he will have a useful stump

Dr. A D Bevan, Chicago—Five years ago I reported a series of cases of old dislocations reduced by operative methods, and in practically all of them we had a complicating fracture The dislocations of the shoulder had no complicating fracture If reasonable efforts at reduction by mechanical means fail, then an *x* ray should be taken to see if there is a complicating fracture It is impossible to make an incision in such a direction as to expose the acetabulum before you expose the end of the femur The capsule should be exposed and freed before the head is exposed. As to the importance in the work of operation on old dislocations of the elbow of sacrificing the triceps tendon, if you expose the joint you will almost invariably find a piece of bone preventing reduction I have obtained better results since I have paid attention to this I do not think I have injured the circumflex nerve and produced resulting paralysis but I rather think we have had an ankylosis, with an atrophy of the deltoid from lack of use I believe that where great force is necessary to reduce an old dislocation of the shoulder we are more apt to obtain a satisfactory result by resection of the head of the bone

Dr J A Blake New York City—I have had very little experience with old dislocations of the hip, but have treated several of the shoulder, and I am inclined to operate rather than make prolonged or forcible attempts to reduce by mechanical means I split the fibers of the deltoid as near its anterior border as possible in order to avoid injuring its nerve supply If this does not afford sufficient access, a supplementary transverse incision is made just below its attachment to the acromion, which also preserves the integrity of its nerve supply Excision of the head of the bone may be done in some cases After removal of the head the functional result is often excellent I have recently seen a resection of four inches of the humerus for new growth, and the result has been almost perfect as regards function As to the elbow, lateral incisions give the best access

Dr G T Vaughan Marine Hospital Service, Washington, D C —We are all agreed that there should be no old dislocations of the shoulder, if one can not reduce them one should operate at once Sometimes this is not done, and they come for treatment I had one case of this kind in which the detached greater tuberosity of the humerus was located directly over the glenoid cavity Several attempts had been made to reduce it, and it was thought with success, but the patient continued to suffer great pain for two months I tried all the various methods of manipulation before cutting I do not approve of the method of placing the foot or the hand in the axilla, having on two occasions fractured a rib by using the foot in the axilla as a fulcrum I made an incision and found the glenoid cavity filled with bone On locating the head of the humerus, I found this bone was the detached greater tuberosity, which had to be dissected out from its attachments over the glenoid cavity Extension and counter extension is the best method by which to treat these cases, as it is least likely to do harm, and if it fail can be followed by Kocher's or some other method

Dr J P Lord, Omaha, Neb —We should take our cue from the recent experience of the orthopedists and adopt the suggestions voiced in last year's orthopedic association rather than resort to excessive force in order to reduce these dislocations It has been my recent experience that this facilitates the reduction of the head of the femur, and it is my belief that injury of the nerves and blood vessels, nerves especially, is produced more by the effect of the lever action which we produce in our manipulation than by the traction If we overcome this resistance by tenotomy and not exert this pressure on the nerves as we do with our forced manipulation evils, we will not produce these dire consequences We should not operate immediately after severe traumatism has been produced by this bloodless reduction Dr Willard did not emphasize that sufficiently Consent to open operation should be obtained if manipulative methods fail I do not think we should undertake the operation until after severe manipulative measures have been resorted to

Dr Charles A Powers, Denver—A number of years ago I saw many unreduced dislocations of the shoulder at the Chambers Street Hospital in New York, and so far as I can remember none which had been out more than ten or twelve weeks was replaced without operation At that time I carefully studied the paper of Kocher, which many of you remember reading fifteen or twenty years ago and in which he stated that old dislocations could be reduced by his well known manipulative methods I was never quite able to understand Kocher's reasoning or his results in old dislocations The adhesions must be thoroughly broken up before reduction by any method of manipulation The breaking up of adhesions must be done, however, with utmost caution I am heartily in accord with Dr Willard in thinking that open operation should be resorted to more frequently I would like to put on record a case of intracoracoid dislocation of the shoulder of four months' standing which, to my surprise, was easily replaced after from eight or ten minutes of manipulation This was in a woman of over 60 years, a patient of Dr P V Carlin of Denver Where an old luxation can be replaced by manipulation it is, of course, best to do so, but we are always to bear in mind the dangers attending too forcible manipulative effort

Dr Willard—Anklyosis of the shoulder joint is an unfortunate condition, especially for a woman, and resection of the head of the humerus is often preferable The breaking up of adhesions in an old dislocation is the most dangerous part of a reduction Open arthrotomy with resection of the fragments is often the better operation

---

Foam-Producing Power of Urine, Aphrometric Test.—A Bignon of *Lima*, Peru, calls attention to a means of testing the urine by its power to produce a durable foam when shaken up with water and acetic acid The *Boletin de la Academia Nacional de Medicina* 1904, ii, No 1, contains his communication on the subject with detailed accounts of his tests He establishes as the standard the number of cubic centimeters of the urine for one hour, diluted with water to 200 c c, which will produce a foam lasting for half an hour when shaken up for one minute with 100 c c of a solution of acetic acid (15 c c of acetic acid to the liter of water) In normal conditions about 1 5 c c to 3 5 c c of urine are required to produce this result, but in abnormal urine a much smaller amount is sufficient When the foam can be induced with less than 1 c c of urine it should be regarded as suspicious He is now studying the application of the test to milk wines, etc He calls it the aphrometric test, from the Greek word *aphros*, foam The term aphrodisiac is derived from the same root, from the legend that Venus (Aphrodite) was born from the foam of the sea

AUTOCHTHONOUS SINUS THROMBOSIS OF THE CEREBRAL DURA

WITH A REPORT OF THREE CASES *

WILLIAM G SPILLER, M D
Professor of Neuropathology and Associate Professor of Neurology in the University of Pennsylvania,
AND
CARL D CAMP, M D
Assistant in Neuropathology in the University of Pennsylvania
From the Wm Pepper Laboratory of Clinical Medicine University of Pennsylvania (Phœbe A Hearst Foundation)
From the Pennsylvania Training School for Feeble minded Children
PHILADELPHIA.

While secondary thrombosis, such as follows middle-ear disease, has elicited great interest and been carefully studied in recent years, especially on account of its surgical treatment, the primary form, the autochthonous sinus thrombosis, because of its indefinite symptomatology, its uncertain treatment and its comparative rarity, has received much less attention

Since the year 1899 there have come under our observation three cases of autochthonous sinus thrombosis

The first case, reported by Drs Wadsworth and Spiller,[1] is as follows

CASE 1—The patient, a boy, aged 7 years, according to his mother's account, had always been in good health and had been bright at school On March 3, 1900, at 1 30 p m, he complained of headache and vomited, at 3 p m he became unconscious, and at 9 20 p m he was taken to the hospital At that time he was still unconscious, the veins of his face were engorged, the pupils dilated and immobile, the pulse weak and rapid, and the respirations slow and irregular (Cheyne-Stokes type) The temperature varied from 99 4 to 100 degrees Fahrenheit Cyanosis was not present He reacted to irritation with a pin Death occurred at 12 30 p m the following day, March 4

Autopsy—At an autopsy held on the same day nearly a pint of clot and fluid was found in the ventricles of the brain, and a clot was found partially occluding the jugular foramen on the left side Further examination showed that a clot had formed in the united veins of Galen at their union with the straight sinus The thrombus was oval in shape, about three quarters of an inch long by one-half inch wide, and consisted, as shown by the microscope, of recently clotted blood

The superior longitudinal sinus was entirely occluded and calcified in its middle portion This occlusion was probably the result of a previous thrombosis The blood from the anterior portion of the superior longitudinal sinus had formed a new passageway between the layers of the falx cerebri. This passageway was not lined by endothelial cells, and conveyed some of the blood from the superior longitudinal sinus to the straight sinus at its junction with the inferior longitudinal sinus, and some of the torcular Herophili The thrombus formed in the united veins of Galen had evidently caused the hemorrhage into the lateral ventricles and death

The second case was reported by Dr S McC Hamill[2] and is included here because Dr Hamill gave the brain to us for microscopic study His clinical notes abbreviated are as follows

CASE 2—No history of syphilis in the mother was obtained The patient was born normally and was not asphyxiated The temperature was slightly elevated from the second day after birth On the seventh day after birth a papular eruption developed on the face and the temperature rose to 104 degrees There was no gastrointestinal disturbance On the fourteenth day marked twitching of the muscles of the right eye and constant lateral rotation of the head were observed General convulsions did not occur The child was somewhat cyanosed and nursed poorly, but did not cry The next day the child was somewhat better, but on the sixteenth day the temperature rose to 100 8 degrees and he vomited a large quantity of altered blood and passed several tarry stools The face became much cyanosed. Death occurred on the same day

Autopsy—At the autopsy, twenty hours later, several thrombi were found in the umbilical arteries The liver was abnormally large The brain showed a large mass of clotted blood overlying the left hemisphere, more marked anteriorly This extended into the substance of the brain, causing some destruction of tissue Overlying the left hemisphere was a less marked hemorrhage

The superior longitudinal, the left lateral, the straight sinus and the veins of Galen contained firmly organized thrombi The veins of the brain were distended with blood and some of the superior cerebral veins, on the left side, contained thrombi Both lateral ventricles were dilated and contained considerable blood, especially the left

Microscopic Examination—There was no round celled infiltration of the pia mater, of the medulla oblongata or cortex and the walls of the blood vessels were not thickened The pia about the medulla oblongata was infiltrated by a great number of red blood corpuscles, as was also the optic chiasm The optic chiasm did not stain well by the Weigert hematoxylin method, probably because it had been kept in formalin There was no cellular infiltration about the blood vessels of the cortex Sections taken from portions of the cortex showed numerous minute hemorrhages and intense congestion of the capillaries of the tissue The extensive hemorrhage had destroyed the upper part of the cerebral hemispheres, including the paracentral lobules, so that the Betz cells could not be studied

A third case is a recent observation The clinical notes obtained from the case-book of the Pennsylvania Training School for Feeble-Minded Children, of which institution the child was an inmate, are as follows

CASE 3—S M, female, 15 years of age at the time of her death. Seven years previously it was noted that her gait was peculiar and was described "as if she were walking on eggs This probably means that the child was spastic There was unilateral exaggeration of the knee jerk Mentality was low and vision was imperfect Epileptic attacks occurred and usually began in the arms and face, finally involving the entire body

Aside from her mental condition, which steadily deteriorated, there was no change noted until four months before her death, when it was observed that while not unable to walk, she disliked to do so and kept her chair as much as possible Her sight had become still more defective and co ordinate movements were impaired, although the grade of imbecility prevented accurate tests No areas of anesthesia were found The child was peevish and prone to cry without cause

Her condition gradually became worse until locomotion was impossible In bed, her thighs were flexed on her abdomen and her legs on her thighs During the last three weeks of life great swelling of the feet with a tendency to the formation of blebs was observed Speech was impossible for three weeks prior to her death, and for the last five days lifting her chin and so permitting fluids to gravitate to the stomach was the method of feeding her Rise in temperature did not occur until the day before her death Her heart action, pulse and respirations were regular and normal

A record of the number of epileptic attacks shows that in 1901 she averaged eight per month, the highest number in any month was eighteen and the lowest was three, in 1902 she averaged the same, but the highest in one month was sixty five and the lowest was two, in 1903 she had forty three attacks in January, eight in February, three in March and nineteen in April She died May 18, 1903

Autopsy—At the necropsy made May 19, the brain was found to be very edematous The superior longitudinal sinus one lateral sinus and the veins of Galen were thrombotic

* Read at the Fifty fifth Annual Session of the American Medical Association, in the Section on Pathology and Physiology and approved for publication by the Executive Committee Drs V C Vaughan Frank B Wynn and Joseph McFarland

[1] Proceed of the Path Soc of Philadelphia Oct 1900 p 207

[2] Archives of Pediatrics 1903 p 264

Many of the blood vessels on the superior surface of the brain were occluded and a small collection of purulent matter was found about one of the blood vessels of the parietal lobe The brain weighed 1,000 grams

There were no signs of the thymus gland

The right lung was not especially congested It was crepitant No distinct tubercles were found It weighed 170 grams The left lung was much more congested and appeared to be in a state of red hepatization The upper lobe was congested, but not so much as the lower A piece of the lower lobe sank when placed in water The left lung weighed 280 grams

The heart was not especially fatty A chicken fat clot was found in the right ventricle and one also in the left auricle The valves were normal The weight of the heart was 145 grams

The liver was not enlarged, but moderately congested

The kidneys and spleen were normal

The lower limbs were somewhat atrophied The spinal cord examined macroscopically, appeared normal

The brain and cord with their membranes were removed and preserved for microscopic study

Sections from the paracentral lobule from each side showed considerable round-celled infiltration of the pia, with the blood vessels greatly congested and their walls thickened The capillaries of the cortex, especially on the left side were unusually prominent and a moderate round celled infiltration was found about them The Betz cells were apparently normal

Within a blood vessel taken from the cortex was found a large mass consisting chiefly of multinuclear cells, about this blood vessel there was a slight round celled infiltration Another blood vessel showed a marked cellular infiltration about it The cells here were multinuclear and had probably migrated from the blood vessel A blood vessel from the choroid plexus was surrounded by a very intense cellular infiltration, the cells being chiefly multinuclear The blood vessel in this section was occluded by a dense mass consisting apparently of fibrin A section from the left lateral sinus showed the sinus filled with a partially organized thrombus, no endothelial lining was found The optic chiasm was not degenerated, but a moderate round cell infiltration was found in the pia about the chiasm

The right and left third cranial nerves were normal

A moderate amount of round cell infiltration was found in the pia mater of the medulla oblongata and the walls of the blood vessels here were much thickened The anterior pyramids were fairly well stained by the Weigert hematoxylin method

Sections through the cervical enlargement showed no distinct round cell infiltration of the pia, and the nerve cells of the anterior horns appeared normal The crossed pyramidal tracts were very distinctly, but not intensely, degenerated The direct pyramidal tracts, by the Weigert hematoxylin method were not affected

The mid thoracic region showed the same degree of degeneration of the crossed pyramidal tracts as was seen in the cervical region Cellular infiltration was slight throughout the spinal cord

The degeneration of the crossed pyramidal tracts extended down into the lumbar region, and disappeared upward in the medulla oblongata The microscopic examination showed the presence of lesions like those of cerebrospinal syphilis The disease was probably hereditary in this case, and in all probability had caused the thrombosis of the dural sinuses

These three cases belong distinctly to that class in which the thrombosis is due to a general bodily condition Primary sinus thrombosis, or that form which is not due to direct extension of disease processes of the face or head, has excited a certain amount of interest during many years

Th v Dusch[3] collected 58 cases of sinus thrombosis, of which 32 were due to gangrenous, erysipelatous or suppurative inflammation of parts of the body whose vessels are in close connection with the sinuses In 4 the thrombosis appeared to result from tumors, etc, causing pressure on the sinuses or internal jugular veins Fifteen cases were supposedly caused by lessened circulation from debilitating diseases, especially in those already in feeble health, as in children or the aged In 6 cases no cause could be ascertained One case he added as a supplement to his paper

Comprehensive papers on the subject of sinus thrombosis have also been written by Lancial[4] and by J A Lidell,[5] the latter author having collected a number of cases Lancial collected 7 cases from the literature which he considered as cachectic in origin, i e, as produced by a debilitated condition of the organism The cases that he collected were those reported by Tuckwell,[6] Corazza,[7] Wiglesworth,[8] Rotch[9] and Grancher[10] Rilliet and Barthez[11] reported 18 cases, and Bouchut[12] 35 cases of cachectic thrombosis

In addition to the cases referred to above, we have studied cases reported by Fisher,[13] Trevithick,[14] Holscher,[15] Nonne,[16] Meigs,[17] Good,[18] Voss,[19] Ehrendorfer[20] Richardson,[21] Hoffman,[22] Reinhold[23] and Phear[24]

Primary sinus thrombosis is regarded by some as especially a disease of childhood and old age, the two extremes of life when the animal organism is least prepared to stand the strain of debilitating influences The predisposing causes are variously given Von Monakow[25] gives as the causes long-continued diarrhea, especially in children, great loss of blood long-continued suppuration, carcinoma tuberculosis chlorosis and anemia

According to Oppenheim,[26] primary sinus thrombosis is, as a rule, a result of cardiac weakness, it is, therefore, called marasmic He also states that in children it is generally due to exhausting diarrhea, and in adults may develop in the terminal stage of exhausting diseases—tuberculosis or carcinoma, more rarely in the course of the acute infectious diseases He mentions Bollinger as having established the fact that chlorosis often produces a sinus thrombosis

Bouchut,[12] in his statistics of cases occurring in children, gives the following table of causes

Chronic enteritis	5 cases
Measles and catarrhal pneumonia	2 cases.
Chronic pneumonia	5 cases
Phthisis	8 cases
Anasarca without albuminuria	1 case.
Chronic albuminuria	3 cases
Pertussis and pneumonia	7 cases.
Gangrene of the mouth	1 case
Diphtheria	2 cases
Scrofulous cachexia, tuberculosis of bones lungs and intestines	1 case

Bouchut calls attention to the fact that 23 out of the

35 cases he studied developed after pulmonary affections

Fourteen of the cases that we have collected from the literature, including our own, were in children The predisposing causes in these cases were pulmonary affections in 3 cases, long-continued suppuration in 2, and diarrhea, tubercular peritonitis and marasmus in one each In the other 6 cases there was no history of any predisposing cause, the cerebral symptoms being the first sign of ill health It is possible that in two of these six cases, namely, the case reported by Holcher[6] and in our first case, where the blood from the superior longitudinal sinus had formed a new passageway between the layers of the falx cerebri, which was not lined by endothelium, that the abnormal circulation predisposed to thrombosis

Murchison[27] is said to have been the first to call attention to the fact that sinus thrombosis is found at autopsy when death is due to syphilitic cachexia He reported 2 cases, both of acquired syphilis, one in a woman, 27 years old, who had extensive syphilitic deposits on the dura and whose sinuses were full of "dark red coagulum" In the other, a gummatous deposit was found on the inner surface of the dura, extending about the left lateral sinus, the lumen of which was obliterated Murchison himself does not attribute the thrombosis to syphilis *per se*, but mentions its presence only incidentally, as in both his cases there was extensive necrosis of the cranial bones and disease of the dura, it might be questioned whether these two cases could be considered as instances of primary sinus thrombosis

In our third case there were signs of cerebral syphilis, and this disease was probably the cause of the sinus thrombosis It seems as though *a priori*, syphilis, whether hereditary or acquired, would be a likely cause of sinus thrombosis, though neither v Monakow nor Oppenheim speaks of it

The degeneration of the pyramidal tracts in our third case is very uncommon in sinus thrombosis

Childbirth sometimes causes thrombosis of the sinuses, probably more often when there is copious hemorrhage, as in a case quoted by v Dusch In this case peritonitis also was present

Chlorosis or anemia has been the cause in several cases, the anemia lasting from one to six months and followed by the sudden onset of cerebral symptoms and death

In a case reported by Ogle, long-continued disease of the rectum was the only discoverable cause A short time before the patient's death the power of speech was lost, but no other symptoms were observed She died of asthenia, and at the autopsy thrombosis of the superior longitudinal and left lateral sinuses was found The inferior longitudinal sinus and the venæ Galeni were found partially obstructed

Ogle[28] also reports a case of sinus thrombosis following pneumonia in a young man aged 26 He suddenly became unconscious and hemiplegic At autopsy the superior longitudinal, left lateral and left petrosal sinuses were filled with a firm, reddish-brown and tightly adherent clot The cerebral veins were all engorged The brain substance was softened in places, and in the posterior and inferior part of the left middle lobe of the cerebral hemisphere was an abscess the size of a hazelnut

A case mentioned by v Dusch,[1] in a girl aged 12, who developed thrombosis of the superior longitudinal sinus during an attack of typhoid fever, probably belongs also to that class of cases where thrombosis of the cerebral sinuses occurs during the course, and usually near the termination of an acute infection In the second case described in our paper, a baby two days old, the clinical history pointed to a general infection, which was followed by the sinus thrombosis

In connection with those cases caused by anemia, a case reported by Nonne[10] is of interest A woman had a large uterine myoma Probably from the metrorrhagia caused by this, she became anemic A little later she suddenly developed cerebral symptoms, and died in four days The autopsy showed thrombosis of the superior longitudinal and lateral sinuses The cortex was hyperemic, but there was no degeneration of the brain substance

In a case reported by Wiglesworth,[8] dementia was present, and this condition, he thinks, may have caused the thrombosis, but the development of severe pulmonary symptoms before the appearance of the cerebral, and the presence of pulmonary lesions at the autopsy, make his conclusion doubtful In another case, reported by the same author, the patient became insane for six days, and then died suddenly At the autopsy a sinus thrombosis was found which, from its appearance, might have been several days old A recent hemorrhage into the ventricle was also found He thinks that in this case the acute insanity was a symptom of the thrombosis, and that death was due to the hemorrhage The patient had previously been in good health, and there was no known cause for the thrombosis

When it comes to a consideration of the immediate cause of the thrombus formation in the sinuses, we are on a very uncertain footing Various theories have been advanced, all of which lack definite proof Von Monakow[25] thinks that sinus thrombosis gives a well-defined symptom-complex, and yet he speaks of its resemblance to meningitis He makes two groups of sinus thrombosis—the marantic and that depending on inflammation of the cerebral veins or the pyemic form He says that the slowing of the circulation in the brain, such as may occur in those afflicted with carcinoma, in emaciated children, in the aged, etc, has been supposed to cause thrombosis, especially if the cardiac action is weak This view is at present far from proof

Baumgarten has shown that blood in a vein tied at each end so that all circulation is prevented, may not coagulate even after weeks, provided the occlusion has been made aseptically and the sinus wall is healthy The same blood, even after weeks, will coagulate if removed from the sinus, so that, as shown by Brucke blood remains fluid if it is in contact with a living healthy vessel wall, even if the vessel is tied

Von Monakow[25] says that there is no doubt that thrombosis of the cerebral sinuses and veins occurs after long-continued diarrhea in small children, after great loss of blood, in long-continued suppuration, in persons with carcinoma, tuberculosis, typhoid fever etc The coagulation, however, does not depend on the feebleness of the circulation, nor the supposed thickening of the blood but on changes in the walls of the vessels (loss of endothelial lining) Zahn has shown that the endothelium may be lost from chemical and thermic causes, that are active in marasmus He thinks, also, that the death of certain elements of the blood, white blood corpuscles, or the blood plaques may cause sinus thrombosis, as in chlorosis Virchow years ago, showed that in a large number of cases the coagulation of the blood precedes phlebitis, and that phlebitis followed by coagulation rarely occurs

---

[27] Trans. Path Soc of Lond vol xiii p 250

[28] Trans Path Soc of Lond vol vi p 30 also vol x p. 31

Recent investigations in the coagulability of the blood by Leo Leob[29] gave some important results that bear on this subject This author found that the presence of certain bacteria or their toxins in blood plasma increased its coagulability in test-tubes, and also in the peritoneal cavity There was a difference in this activity according to the bacteria used, for instance, the staphylococcus pyogenes aureus was more active than the bacillus coli The absorption into the blood of tissue fluids increases the coagulability of the blood plasma A piece of muscle put into fresh-blood plasma increases its coagulability The same is true when a piece of blood vessel is placed in the plasma This action is, to a certain extent, specific, tissues from the same kind of animal as the one from which the plasma was obtained being more effective

It has not been proved that the endothelium exerts an inhibitory effect on the coagulation of the blood, but probably acts merely by preventing absorption of certain constituents from the tissues, and it also produces a smooth surface much in the same way as paraffin would only much better It seems most likely that in all these cases the coagulability of the blood is increased either by the presence of bacterial toxins or bacteria, or by tissue products

Virchow pointed out that the most commonly observed seats of sinus thrombosis are the cranial sinuses and the veins of the lower extremities and of the true pelvis, and that the reasons therefor are anatomic The fact that there are numerous fibrous bands crossing the cranial sinuses, that the sinuses are triangular in shape instead of circular, as are other blood vessels, thereby causing increased surface and so increasing resistance, that the tributary veins enter the superior longitudinal sinus at a right angle or sometimes even an obtuse angle to the course of the blood current, that in the cranium there is no muscular action to accelerate the current, and that the sinuses *in situ* are held open by their adhesions in spite of a diminished quantity of blood, are all factors that tend to produce a stasis in the blood current

In connection with the etiology, it is well to say that there are many cases reported which might have been regarded as primary, except for the complete history or postmortem examination, such as those caused by a furuncle on the face, the removal of a nasal polyp, an abscess of the antrum of Highmore, etc

In the primary form the superior longitudinal sinus is the most frequently affected This is in great contrast to those cases that are secondary to otitis media, in which the lateral sinus is chiefly affected Thrombosis, which is secondary to nasal or facial conditions, frequently occurs in the superior longitudinal sinus

In the primary form, the superior longitudinal sinus is not the only one affected The thrombosis may be very extensive, and involve all or nearly all the dural sinuses The superficial veins are generally congested and may be thrombosed, and the same is true of the veins of the choroid plexus In some of the cases extensive hemorrhage had occurred into the ventricles, and was the immediate cause of death, in other cases the ventricles were free, but cortical hemorrhages were found, in still other cases no hemorrhage was seen anywhere

Abscess or areas of softening, are rarely reported in primary thrombosis

In the third case of our paper the endothelium of the superior longitudinal sinus was destroyed

The appearance of the thrombus is very variable, according to its age It may be a dark red coagulum, or it may be completely organized so that the sinus resembles a fibrous cord

A CASE OF EARLY ACUTE PANCREATITIS WITHOUT HEMORRHAGE *

H H GERMAIN, M D

AND

H A CHRISTIAN, M D

BOSTON

Of the many cases of acute pancreatitis reported in the literature, most present quite advanced lesions The largest number are examples of hemorrhagic or of necrotizing pancreatitis with extensive destruction of the organ A few are cases of focal suppurative lesions The study of these cases has not thrown great light on the etiology and histogenesis of the lesions, but our present knowledge of the condition has been gained mainly from animal experimentation

In animals the pancreas has been treated in a great variety of ways Some of these, as injections of chromic acid, present conditions which manifestly play no part in the causation of the natural disease in man Others such as injections of digestive ferments (papain), bacteria, gastric juice or bile, imitate conditions that, to say the least, might occur in man Of these the entrance of bile seems to offer the most satisfactory explanation of many of the cases of acute pancreatitis, and it has been given first place in the etiology of the disease

Cases in man showing very early lesions are rare and yet from these alone can the correctness of the deductions made from animal experiments to the natural disease in man be proven This case is reported because it shows an early lesion and presents certain peculiarities not generally found in other cases Furthermore, there is no evidence of bile having entered the organ, and the inflammatory lesions are unassociated with hemorrhage

The clinical narration of the case is as follows

History—Katherine L, age 29, married, was admitted to the surgical side of the Boston City Hospital on the service of Dr Gavin,[1] with a provisional diagnosis of appendicitis Family history negative Past history shows no severe illness or accident Last catamenia four months ago Constipated for past few weeks

Present Illness—Three days before entrance gradual onset of moderately severe pain in left lower abdomen, becoming general in a few hours Pain extreme and most severe in epigastrium Patient vomited several times daily Vomitus consisted of food ingested and was at times bile stained Chill two days previous lasting about half an hour Last movement of bowels four days previous No change in urine noted

Examination—Well developed, obese Temperature 101 2 degrees, pulse 110 of poor volume and tension Tongue dry with thick brownish coat Skin pale, with a slight yellowish hue Decided pallor of mucous membranes Heart sounds faint, no murmurs audible Lungs negative Abdomen not distended Slight general tenderness, which is marked in epigastric and right hypochondriac regions No mass to be felt General normal tympany No dullness in flanks or evidence of free fluid No edema Moderate muscular spasm above umbilicus Liver dullness from fifth rib to two inches below costal margin Edge of liver is smooth and not tender Spleen not palpable. Vaginal examination shows normal vagina with a lacerated cervix and a somewhat enlarged uterus Urine A slight trace of albumin, no sugar, sediment not examined Blood not examined

---

[29] Personal communication

* Read at the Fifty-fifth Annual Session of the American Medical Association in the Section on Pathology and Physiology and approved for publication by the Executive Committee Drs V C Vaughan, Frank B Wynn and Joseph McFarland

[1] We are indebted to Dr Gavin for the privilege of using the clinical history of this case

Treatment and Course—Patient was given a high enema with fair result and strychnia, gr 1/[illegible], every few hours She seemed considerably relieved by the enema and was comfortable until 9 30 p m, when she became thirsty, restless and with a rapid and irregular pulse At this time she vomited and symptoms of collapse became more extreme Active stimulation failed to give any reaction and death occurred about 3 30 a m

Diagnosis—As the patient was under observation only ten hours there was little time for careful study and no definite clinical diagnosis was made Gallstones, gastric ulcer, pancreatitis and appendicitis, with abscess of the liver were considered in the differential diagnosis Absence of liver tenderness, together with regular contour though not excluding liver abscess, made the possibility less likely It was impossible to exclude the other three conditions, but the rapid onset of collapse without any evidence of hemorrhage made the diagnosis of acute pancreatitis more probable than anything else

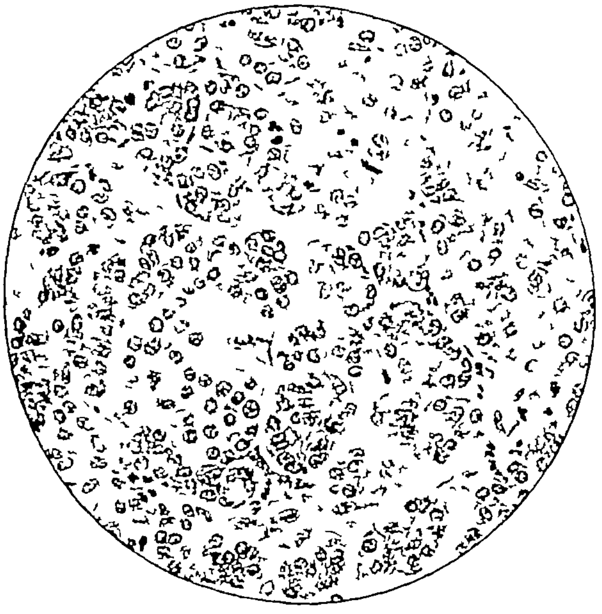

Figure 1

Autopsy—The examination was made twenty three hours after death The body was of a well developed, well nourished woman, 153 cm long, abdominal panniculus 5 cm thick

Peritoneal Cavity Omentum was long, completely veiling viscera and contained much fat, as did the mesentery No fat necroses were found No fluid was present in cavity Mesenteric lymph nodes not enlarged Appendix normal 11 cm long, below cecum directed toward mid line, slightly curved It had a mesentery for entire length which except at distal end was very short Lesser peritoneal cavity normal Pelvis normal

Pleural Cavities Right lung slightly bound to parietes laterally and posteriorly by fibrous adhesions Left normal Pericardial cavity was normal

Heart Weight, 285 gms Just beneath the epicardium over base of heart are numerous ecchymoses 1 to 3 mm in diameter, and of slightly irregular contour Heart otherwise normal Frozen section showed no fat droplets in fibers when treated with glacial acetic acid

Lungs Right shows few fibrous tags At base of both few small ecchymoses beneath pleura Lungs otherwise normal Bronchi and peribronchial lymph nodes normal

Spleen Weight 75 gms Surface slightly wrinkled and showed numerous small irregular slightly elevated whitish patches Except for this normal

Gastrointestinal Tract In tissues about lower end of esophagus there had been a slight hemorrhage The gastric mucosa was in many places hyperemic and there were many minute submucous ecchymoses Duodenum more hyperemic and along tops of mucous folds dark red Other parts of tract pale and contracted

Pancreas appeared normal, though numerous parallel cuts were made through it

Liver Weight, 1,690 gms Smooth On section, grayish red, with scattered small paler areas Markings indistinct Consistence normal Gall bladder distended with dark bile, no stones Ducts normal

Kidneys Weight, 310 gms Capsule strips readily without tearing kidney substance On section, cortex pale, grayish, with glomeruli visible as red points Pyramids dark red with indistinct markings Cortex, 9 mm thick Frozen section shows very great numbers of small fat droplets in tubular epithelium when treated with glacial acetic acid or stained with Sudan III or Scharlach R Adrenals normal Bladder normal

Uterus was enlarged, fundus reaching about to level of pelvic brim Softer than normal Uterine veins distended with blood Tubes and ovaries normal Uterus contained a fetus

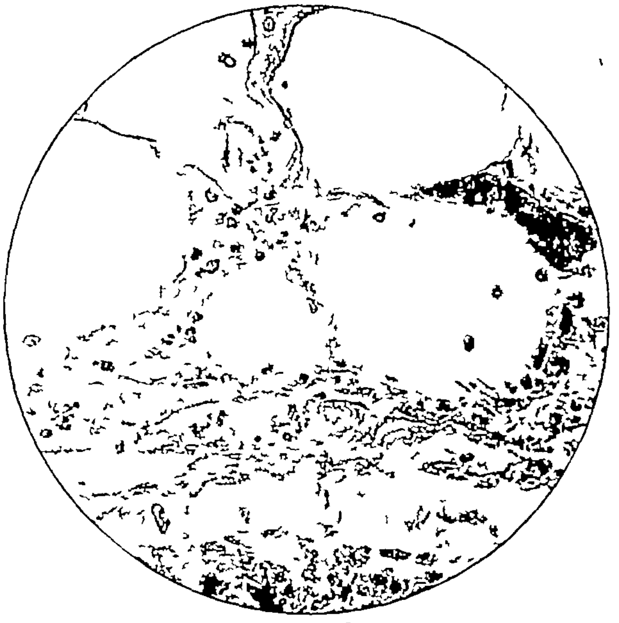

Figure 2

lying in a sac 4 cm in diameter Surface of sac covered with innumerable short villi, giving it a velvety appearance

The fetus was about 1 cm long Uterine mucosa thickened, red and softer than normal Over an area about 3 cm in diameter the mucosa is thicker than elsewhere, placental site Vagina normal Cervix slightly patulous Aorta of small caliber, normal The organs of neck, tongue, uvula, tonsils and brain were normal

Cultures—Heart's blood and lung, sterile

Liver, spleen and kidney, bacillus of colon group

Microscopic Examination.—Liver The liver cells in the central half or two thirds of each lobule contained many large vacuoles Their cytoplasm took a deeper eosin stain than that of the cells of the periphery of the lobule It was granular and many cells showed varying degrees of disintegration Most nuclei of liver cells stained very faintly In the capillaries between these cells, in the cells themselves and their remnants were many polymorphonuclear leucocytes with deeply staining nuclei Spleen negative

Kidney There was an occasional atrophied glomerulus and a few hyaline casts In tubular epithelium there were numerous vacuoles grouped generally in the basal portion of cell

Sections of liver spleen and kidney stained by the Gram Weigert method and with eosin and methylene blue showed no bacteria

Uterus showed normal decidua, no other change Fallopian tube normal

Pancreas shows two forms of lesion, one diffuse, the other focal The diffuse lesion consisted of the presence of polymorphonuclear leucocytes scattered between the acini of the pancreas These lay in the small mount of interacinar connective tissue and only very rarely penetrated between the epithelial cells of an acinus (Fig 1) The leucocytes varied in number in different sections, but only rarely were they found in large numbers in any given field On the other hand, in only one section of a considerable number examined were they absent In places they were scattered similarly in the interlobular connective tissue and between the fat cells (Fig 2).

The focal lesion consisted of not very numerous scattered areas of necrosis and of cellular infiltration The necrotic areas were generally quite small and as a rule involved the pancreatic parenchyma In addition a few definite fat necroses involving small groups of fat cells were found Into some of the larger areas of necrotic pancreas many polymorphonuclear leucocytes had wandered and their tissue disintegration was quite marked These leucocytes stained poorly In certain parts of the interlobular connective tissue polymorphonuclear leucocytes were present, in other parts, cells considerably larger than a polymorphonuclear leucocyte were found These cells had a round or oval vesicular nucleus and a considerable amount of vacuolated cytoplasm Both forms of cell infiltrated the interstitial tissue in scattered foci In some places in the interstitial tissue there was a moderate amount of fibrin Here and there a few red blood corpuscles appeared, but none of the lesions in the pancreas were hemorrhagic in character Some sections show the capsule of the pancreas In it are numerous polymorphonuclear leucocytes which frequently appear to be in lymph channels From the capsule the leucocytic infiltration extended in places along interlobular septa into the pancreas (Fig 3)

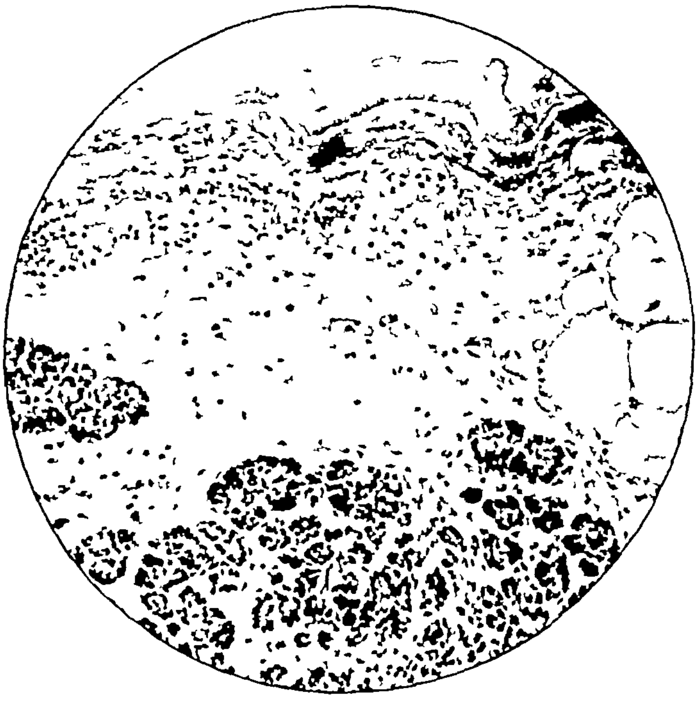

Figure 3

In general the pancreas stained less well than the other organs The acinar epithelium, except in the necrotic areas, however, showed no lesion The islands of Langerhans were normal in appearance The larger ducts frequently showed desquamation of their epithelium and in the lumen of the smaller ducts and acini a hyaline material was generally found The interstitial tissue is not increased in amount The blood vessels show as lesions

Sections stained for bacteria by the Gram Weigert method showed groups of organisms consisting of cocci, often in short chains and a less number of fairly large bacilli These were sometimes found where there was leucocytic infiltration of interlobular connective tissue Some were present in the capsule Bacteria also occurred where there was no discoverable lesion of the tissue and some veins contained considerable numbers Bacteria were not present in the larger lesions with definite necrosis or marked leucocytic infiltration, and they were not found scattered in the parenchyma of the pancreas Of the bacteria present the greater number tinctorially and morphologically resembled streptococci

Anatomic Diagnoses—Early acute pancreatitis and peripancreatitis Central necroses of the liver with leucocytic infiltration Marked fatty degeneration of kidneys Subpleural ecchymoses Subpericardial ecchymoses Submucous ecchymoses and congestion of stomach and duodenum Slight periesophageal hemorrhage Chronic fibrous pleuritis, right side Chronic perisplenitis Pregnant uterus

REMARKS

This case is one of acute pancreatitis of less than four days' duration from the onset of the first symptoms The clinical history is a fairly characteristic one Abdominal pain and tenderness most evident in the epigastric region occurs in a fat woman This is accompanied by constipation, vomiting, fever, and finally marked collapse Autopsy shows but slight macroscopic lesions There are scattered ecchymoses in the pleura and pericardium, and congestion of the stomach and duodenum There is a marked fatty change in the kidney and extensive central necrosis of the liver All of the findings point to an intense intoxication

The source of this intoxication seems to be in the pancreatic lesions already described Their etiology is not clear There is no indication of any entrance of bile into the organ There is a duodenitis Assuming this to be the primary lesion, extension may have taken place to the pancreas either by way of the pancreatic ducts or by direct extension possible in the close connection existing between the duodenum and head of the pancreas The pancreatic ducts show no lesion other than desquamation, and this may be simply a postmortem change There is evidence of an inflammatory process extending along the interlobular connective tissue and the capsule of the organ, eventually between the acini themselves Associated with these lesions are bacteria, especially streptococci The method of the extension of the process bears a resemblance to the conditions found in erysipelas and has suggested the name erysipelatoid for this type of pancreatic lesion However, the relation of the bacteria to the lesions is not always evident, and postmortem multiplication, possibly postmortem invasion may have taken place So this can not be said to be a clear case of pancreatitis of bacterial etiology

The interest of the case lies in its short duration, the extent and character of the inflammatory lesion the slight degree of necrosis of the pancreas and fat tissue and the absence of hemorrhagic lesion Such a case strengthens the belief in the inflammatory nature of acute hemorrhagic pancreatitis Seitz [2] discussing the point as to whether severe pancreatic hemorrhages are inflammatory in origin, asks the question "Warum sind keine Falle vorhanden, bei dened es nicht zur Blutung gekommen ist, wo also eine reine Entzundung so plotzlich todte?" Oser[3] was able to find only two cases those of Cavley and Kennan, with which to answer this question However, neither of these cases is convincing as microscopic examinations were not made Our case serves to answer the question asked by Seitz and shows the possibility of an inflammatory lesion of the pancreas without hemorrhage but clinically presenting the picture of acute hemorrhagic pancreatitis

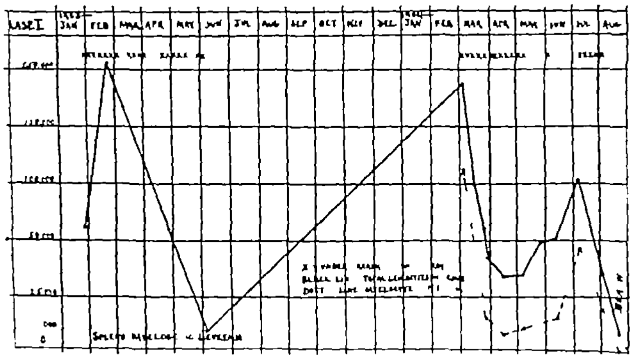
X-RAY THERAPY IN LEUKEMIA

A PRELIMINARY REPORT WITH SPECIAL REFERENCE TO LYMPHATIC LEUKEMIA

JOSEPH A CAPPS, M D
AND
JOSEPH F SMITH, M D
CHICAGO

The first recorded utilization of the x-ray for the treatment of leukemia was by Pusey,[1] who observed no effect whatever in a case of the splenomyelogenic type, but in one of the lymphatic type he noticed a marked diminution in the size of the glands More recently a fresh interest in the subject has been aroused by the favorable reports of Senn,[2] Brown[3] and others [4]

In all we have seen reports of 11 cases of well-verified leukemia treated in this way All but one of these belonged to the splenomyelogenic type In every instance the splenic tumor decreased in size in 3 cases becoming barely palpable The leucocytes in all cases excepting Pusey's diminished in number Four reporters record a white count under 10,000, with entire disappearance of the myelocytes An improvement in the hemoglobin and red corpuscles always took place, but was frequently followed by a decline Death occurred in 3 cases, one will soon result fatally The others were all much improved at the time of their publication It should be emphasized, however, that none had been observed under treatment for more than eight months



Through the courtesy of Dr Senn we are enabled to report the further course and termination of his published case of splenomyelogenic leukemia and one other hitherto unpublished We are also indebted to Drs Bevan and Herrick for the privilege of using patients in their service at the Presbyterian Hospital In the accompanying table are condensed the salient features of eight cases that have come under our observation The typical blood changes are graphically illustrated by two charts, one of splenomyelogenic, the other of lymphatic leukemia

Case 1 shows the inhibiting influence of the x-ray on the leucocytes and the constant tendency for the leucocytes to multiply when the treatment is discontinued The count toward the last fell to the normal but the myelocytes never entirely disappeared

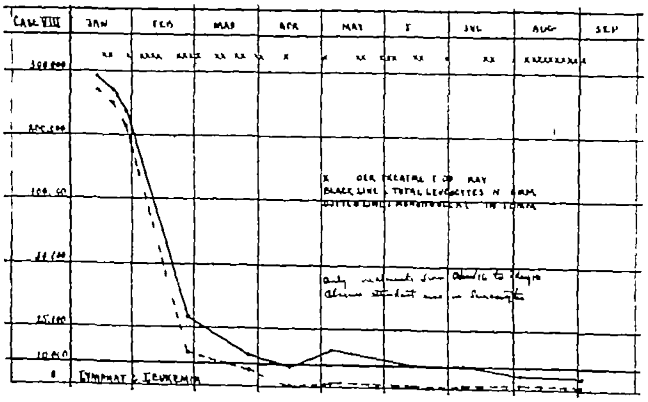
LYMPHATIC LEUKEMIA

The only well-reported case observed during treatment is the one by Pusey above referred to The glands and spleen in his patient twice went down to nearly normal size under the treatment, but recurrence and finally death took place He found no marked fall in the leucocytes

In our series of 6 lymphatic cases, death resulted in 4, and it will be noticed that 3 of these ran an acute or subacute course, the fourth showed a great shrinkage of the gland tumors and an improvement in the blood before death took place The remaining 2 cases exhibit a steady continuous improvement in the blood, glands and spleen The blood chart of Case 6 is typical of both, not only does the leucocyte count become normal, but the differential count gives no hint of the blood disease The spleen and glands in both patients remain somewhat enlarged

SOME GENERAL DEDUCTIONS

1 The action of the x-ray in leukemia seems to be of two kinds (a) A local influence on the spleen and glands, characterized by an inflammatory reaction and later by a breaking down and disintegration of the gland tissue (b) The formation of toxins which have an inhibitory action on the manufacture of leucocytes by the bone marrow It is well known that acute infections occurring in leukemia, such as pneumonia, septicemia or terminal infections, tend to inhibit the production of white corpuscles and often cause a reduction in the size of the spleen or gland tumors The x-ray toxins may be compared to those produced by such infections



2 In no recorded instance of either lymphatic or splenomyelogenic leukemia has the spleen tumor entirely disappeared

3 With the discontinuance of the x-ray, the disease, after varying periods tends to reassert itself

4 Death may take place when the glands and spleen are smallest, and when the white count is normal

5 Acute cases seem to receive no benefit from the x-ray

6 The chronic form of lymphatic leukemia responds to the x-ray even more promptly than the splenomyelogenic type In every instance the glands rapidly softened and dwindled to small proportions

7 The x-ray holds the disease process in abeyance but probably is not curative Yet it is too soon to say that persistent treatment of an early case may not give permanent relief

TRAVEL NOTES—X.*

A WINTER SEMESTER

LEWELLYS F. BARKER, M.D.

CHICAGO

(*Concluded from page 813.*)

MUNICH, July 21, 1904

The unusual attractiveness of Munich as a place of residence is, perhaps, not an unmixed advantage to the medical school, for though it insures a large attendance and affords unusual opportunities to the students for self development in general culture, for the enjoyment of art, music and the theater, it brings to the University of Munich more than its share of the lazy, loitering students who care more for the *Bummelleben*, for which the interesting old city gives such ample opportunity, than for the training of their hands or the perfecting of their minds In the spring and autumn the adjacent mountains seduce to frequent excursions In the winter the *Bal paré*, the *Redoute* and the delights of carnival lead to the squandering of all too many hours that should be devoted to study At all times the restaurant life and café life is there with its peculiar inducements to the sacrifice of time

Two especial attractions appealed not only to the students of Munich during the past winter, but to all residents and visitors Both were novel forms of the dance—one the artistic, music interpreting dance of the American, Miss Isadora Duncan, the other the so called sleep dance or dream dance of the hypnotized, hysterical Mme Madeleine[1] of Paris The latter was the more pathologic in its interest For a time it seemed as if all Munich from the uppermost to the lowest class had been hypnotized by her, everyone you met spoke of her, asked if you had seen her, and wanted to know if she were really hypnotized or if it were all a swindle She was "discovered" in Paris by a "magnetisator," a quack whom she had consulted regarding headaches The "magnetisator" hypnotized her, and by chance he says, while she was in the hypnotic state, played a selection from Chopin To his surprise, so the story goes the patient began to react in the most marvelously plastic way to the musical sounds The artistic attitudes assumed were so remarkable that she was presented in several art studios in Paris and London, the cataleptic attitudes called forth by various suggestions could be maintained long enough for photographic reproduction, and a large series of pictures of her, illustrating "all phases of human emotion unencumbered by any inhibitory influence" are on sale and used as models by artists The "magnetopath" being a practical business man, decided to exploit her He could have chosen no better place than Munich in which to begin operations That city, probably, has the most mobile nervous system in Europe the phenomenal success of "the Duncan" there as compared with her relatively cool reception in hard headed Berlin had sufficiently demonstrated that But how to effect an entrance was the difficulty Hypnotic exhibitions in public are prohibited by law in Germany The public had to be smuggled in in some way under the protection of science The gulf between the "magnetisator" and the medical profession was finally bridged through the intermediation of the Munich Psychological Society and of von Schrenck Notzing a nerve specialist whose offer to present "the Madeleine" as a clinical case to the *Aerztliche Verein* was accepted Some 400 physicians met in the amphitheater of the Medical Clinical Institute The clinical history was read by v Schrenck Notzing The woman, 30 years old, had been a nervous child though actual hysterical attacks had never been noted Examination revealed a moderate degree of anemia, left sided hyperalgesia, hysterical visual fields, and in general the psychic stigmata of the hysterical nature The Parisian impresario was then called in and he, with much Svengali like nonsense—one could feel the medical men in the audience shiver—put the patient to sleep Loewenfeld, von Schrenck Nötzing and other experienced hypnotists examined her and declared that there was no doubt as to the hypnotic condition Professor Thiele, at the piano, tested the reactions of the woman to intensity of tones, velocity of tone sequence, rhythm, height of tone scale, intervals, legato, staccato, consonance, dissonance and the like The reactions were lightning like and consistent the movements of the body produced were undoubtedly marvelous, the contrast between the reaction to waltz music and a funeral march were extreme Under the verbal suggestion of the magnetopath, further, she reacted immediately in correspondence to the most diverse human feelings and emotions

After "waking her" with voice and various absurd movements, the "magnetisator" and his charge withdrew and the discussion was opened Though the chairman of the meeting urged that the discussion should not be made public, this was in the state of tension which existed in Munich at the time too much to hope for The opinions expressed at the meeting soon became public property and a résumé of the proceedings was even written by a physician for the feuilleton of the *Frankfurter Zeitung* The most diverse opinions were expressed, and they were not limited to the character of the case presented, but involved, as might have been expected, the medical ethics of the whole situation Loewenfeld's opinion seemed to be listened to with the greatest respect Though some of the physicians had thought the hypnotism simulated and the whole performance a swindle, Loewenfeld felt sure that the hypnotism was genuine, but gave it as his opinion that the hysterical element rather than the hypnosis was responsible for the artistic attitudes, the hypnosis, perhaps being helpful, since in the hypnotic condition all inhibitory influences are removed, and capacities, which, possessed in the waking condition, but then improperly unfolded owing to shyness embarrassment and distraction, can first be fully exhibited The woman, it was asserted, had no especial training in art and music but that she, through inheritance, must be very susceptible to music is obvious, a fact which may be accounted for some thought, through the history that her mother had been a dancer in Tiflis That no physician has hypnotized Mme Madeleine is a feature of the situation to which attention was more than once called

From all I could see, and trying to weigh as critically as I could the conflicting comments made, I came away from the meeting feeling that Mme Madeleine's performance was qualitatively a mixture of hypnosis, hysteria and hocus pocus, but as to the quantitative relations of the three ingredients I shall venture no guess

The fact that public exhibitions of hypnotism are illegal, of course, made the great public most anxious to see Mme Madeleine The reports of the presentations at the Psychological Society and at the Medical Society whetted the appetite further The way in which the law was evaded was interesting People who desired to see the woman registered their names at one of the Munich bookstores Invitations to attend a "private performance" in the Schauspielhaus were then sent out by the Psychological Society, acceptances were to be accompanied by a subscription of 10 or 20 marks, according to the position of the seats These difficulties helped, as I have said to hypnotize the public The house was sold out, and audiences of musicians, artists actors and the wholesale public viewed the "dream dance" unmolested How great the harm done to the people at large has been it is difficult to calculate Rumor has it that the offices of the hypnotists are being more than ever visited by women and girls who demand that they be hypnotized in order that their slumbering or inhibited talents may be revealed

New Instrument.

SALINE INFUSION AND IRRIGATING FLASK

JOHN J. SHEA, M.D.

BEVERLY, MASS.

This apparatus relates to an improvement in saline infusion and irrigating flasks. As illustration shows, it consists of a chemical glass reservoir, suitably marked in cubic centimeters up to one liter. It is provided at its base with a nipple shaped outlet, to which rubber tube and needle are attached. This glass reservoir is held in place by upper and lower metal rings between which and flask is interposed rubber packing to prevent flask from cracking. These rings are detachably connected, by means of metal rods going through perforated ears in the rings. The upper end of each rod is provided with an eye, to which is connected a handle. The lower end of each rod is threaded and is secured by means of adjustable nuts. These rods pass loosely through perforated ears in upper and lower rings, so as to allow new flask to be substituted if one is broken. On lower rings are three legs serving as support. Thus it can be seen that flask can be either hung up or set down without interfering with the flow of the liquid.

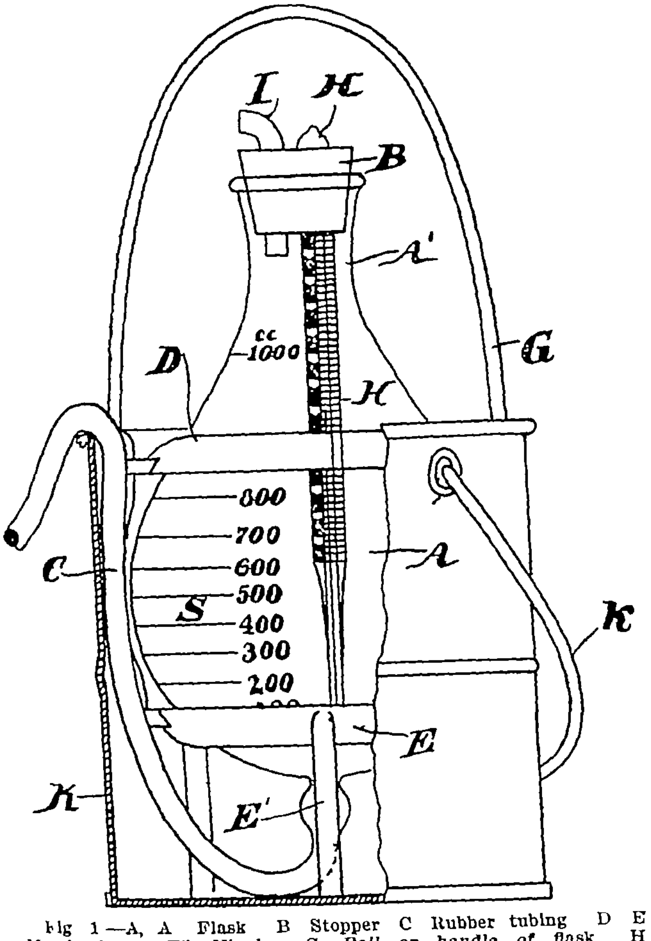

Fig. 1.—A, A. Flask. B. Stopper. C. Rubber tubing. D. E. Metal rings. E'. Nipple. G. Bail or handle of flask. H. Thermometer. I. Inlet for air. K. Coppered tin with handle.

The stopper is made of rubber, containing two perforations, one containing a thermometer for registering temperature of solution and the other a small glass tube, to allow air to enter to compensate the displaced liquid.

I have also provided a coppered tin receptacle, also having a handle, to serve as a vessel in which to boil the solution for purpose of sterilizing it, or for reheating the solution when in bottle. This flask fits with rubber tubing into the coppered tin receptacle and the whole is placed in a box with handle.

In upper part of this box is a compartment in which to carry sterile needle and a concentrated sterile salt solution, an ounce of which added to 1,000 c.c. of water makes a normal salt solution. This solution can be prepared and kept in the flask for emergencies, showing its helpfulness in ambulance calls, railway accidents, etc., beside its convenience to the physician and the hospital.

Clinical Report.

REPORT OF A SYMPTOMATIC CURE OF CONVULSIVE TIC DOULOUREUX BY INJECTION OF OSMIC ACID

JOSEPH RILUS EASTMAN, M.D.

INDIANAPOLIS

History.—Mrs. H., aged 71 years, came to me on July 5, 1904. The case was one of typical intense tic douloureux involving the right side of the face. The first paroxysm occurred about twenty years ago, subsequent attacks gradually becoming more frequent and more severe. Practically all of the many remedies recommended for the relief of this condition had been tried without benefit. All the teeth had been extracted in the belief that perhaps dental caries bore some causative relation to the pain. For almost three months prior to the operation the pain had been excruciating, the attacks occurring with exhausting frequency. The whole right side of the face was exquisitely tender, particularly in the neighborhood of the infraorbital and mental foramina. The tongue was sore and tender at all times, this greatly interfering with speech. During attacks the pain was most acute about the right angle of the mouth and the angle of the right jaw. Violent spasm of the buccinator was almost constantly present during the attacks.

Treatment.—A 2 per cent. solution of osmic acid was injected into the supraorbital, infraorbital and inferior dental nerves at the supraorbital notch and infraorbital and mental foramina. The manner of operating was precisely that practiced by Dr. John B. Murphy and described by him at the Atlantic City meeting of this year. Ten drops of a 2 per cent. solution of the osmic acid were injected into each branch, and two or three drops were forced into the perineural fat of each foramen around the nerve. At the time of the injection of the osmic acid the nerves were drawn with very slight force from the foramina and held during the injection, but the trunks were not stretched as in the operation of neurectasy.

Result.—Up to the present time there has been no return of the pain since its abatement one week after the operation. During the first week several rather severe paroxysms occurred, these gradually decreasing in severity. It is possible that the pain in this case may return, but even if it should, the respite for a few months justifies an operation so easy of performance and attended with so little danger.

An interesting feature of the case was the severe nephritis occasioned by the elimination of the acid. The urine passed during the first twelve hours succeeding the operation showed nothing unusual, however, on the second day nephritis resulted. There were no symptoms either subjective or objective pointing to its onset or presence excepting the appearance of and findings in the urine. The patient did not complain of pain in the loins. Urine passed thirty six hours after the operation showed the following:

Reaction, very slightly acid; sp. g., 1036; color, dark claret. The specimen was centrifuged, and the sediment composed a little over a quarter of the volume. The clear fluid above the sediment was light claret in color, the sediment being dark red. Examination of the fluid portion showed a small amount of albumin, with no sugar, bile or other abnormal substance present. Examination of the sediment showed it to be composed almost entirely of red blood cells. There were no casts, epithelial cells or pus cells. The red blood cells disappeared from the urine on the fourth day.

PROGERIA, A FORM OF SENILISM

Among the still obscure physiologic problems must be reckoned those relating to the mechanism regulating growth and decay. While we are in possession of isolated scraps of knowledge which shed an occasional glimmer of light on the subject, our knowledge can only be described as fragmentary. The studies of the last few years on acromegaly and giantism indicate that the pituitary body has some influence on development though just what this influence is remains obscure. In some cases of dwarfism, too, this gland has been found diseased. In some forms of dwarfism again the thyroid seems to play a part, as is the case in cretinism and allied conditions. Then, again, certain glands seem to bear a relation to certain systems rather than to the body as a whole, an example of this being the curious relation which exists between excessive or premature development of the genitalia and some of the diseases of the adrenal glands. The question as to the factors which delay or accelerate decay, though less frequently studied, is equally as important as that relating to growth. Why is it that in individuals of the same age some are so much older and some so much younger, so far as their tissues and intellect are concerned, than the average individual of that age? Why is it that in the same individual one organ, or group of organs, may be older or younger than the rest of the body structures? To use the term originated by Sir James Paget, what is it that regulates the "chronometry of life"?

In a recent article, Hastings Guilford[1] has reported, under the name of progeria, some extremely interesting cases in which there existed a combination of premature senility and infantilism, but in which the former condition greatly predominated. In all the cases the predominating syndrome of premature decay was far beyond the limits of possible normal variation, and was unassociated with any previous disease which might have acted as a causative factor. Without considering the cases in detail, it will be of interest to briefly sketch salient points in the natural history of the two most characteristic cases, these being so similar that one description will suffice. The disease begins in early infancy with loss of hair so marked that at six months more than half the hair may have disappeared. At the same time the child begins to emaciate. The shoulders are rounded and the chest narrow on account of the lack of development of the clavicles. The head is relatively large, and may resemble the head of hydrocephalus. As the child grows the hair becomes more scanty and turns gray so that as early as the age of seven only a very scanty gray crop may remain. The growth is stunted and the child takes on all the appearances of the decrepitude of age. The skin becomes loose and shriveled, the arteries show senile changes, and the whole appearance and even the mental attitude is that of the adult rather than that of the child. The children are easily fatigued, partly on account of muscular weakness, partly on account of shortness of breath, the latter symptom being of cardiac origin. Physical examination shows a curious mixture of the physical signs of senility and those of lack of development. The skin, the hair, the vascular system, and the ends of the long bones are those of an old individual, and, on the other hand, the shafts of the long bones, the bones of the skull, the teeth, and the mammary glands show marked lack of development. The liver, the blood-forming organs and the genitalia seem to develop in a normal manner. The functions of the body seem to be carried on in a fairly satisfactory manner. The bowels are regular, the appetite is good, and most foods are normally digested, though curiously enough in both well-marked cases the patient was unable to digest fats. Death took place in both cases at the age of seventeen, in one case in an attack of angina pectoris, in the other from cardiac failure.

In the one case in which Guilford was able to procure an autopsy, the same curious mingling of senile and infantile changes was found. There was marked sclerosis of the arterial system, the coronaries and aortic and mitral valves being especially affected. The kidneys and adrenals showed a fibrosis of a typical senile type. On the other hand he noted a persistent thymus, a great lack of development of the clavicles and an undeveloped state of the shafts of the long bones. The liver and thyroid gland were normal, and no definite changes could be made out in the brain or in the pineal or pituitary glands.

In his discussion of the pathogenesis of the disease, the author sums up the condition as being one of "retarded development, combined with premature old age and with indications of some attempt to attain a normal condition." He is unable to explain the causative factors in the disease. There was no evidence that it was due to previous disease of some particular organ, the thyroid, pituitary and brain being normal, and the author evidently does not think the adrenal changes of importance enough to lead to serious results. He compares the cases to the form of infantilism known as ateliosis, and thinks that possibly these may be cases of ateliosis combined with premature senile decay. He neglects to state the condition of the pancreas in the case examined postmortem, and apparently regards this of no moment. In the light of the cases of pancreatic infantilism, recently reported by Bramwell and others, it would have been of interest to have known the condition of this organ in his cases, particularly as in both of them there was a marked aversion to fatty food, and in one there were also periodic attacks of abdominal pain

AID WANTED FOR CONVALESCENT INSANE

It is well known that the average patient discharged from the hospital for the insane, as recovered or improved, is in a most helpless and pitiable situation if he has no friends to look after him, and there are many such In his efforts to obtain employment he is more heavily handicapped than is the discharged prisoner At the very moment, therefore, when he should be protected, well nourished and cheerfully employed, he is plunged into difficulties and discouragements, and frequently is reduced to abject want It is not strange that he too often again succumbs to his malady, neither is it to be wondered at that, in view of this well-recognized danger, convalescent patients are sometimes retained in the asylums by humane superintendents too long for the good of the asylums and too long for their own good, could they be sent out into the world under even a temporary guarantee of safe and wholesome living conditions In this country there are many societies for the aid and encouragement of discharged convicts but none, so far as we are aware, which provides assistance for the recovered patient discharged from a hospital for the insane The general charitable societies, of course, do much to relieve the families who are reduced to helplessness by the insanity of their breadwinners, and in some cases patients are assisted in obtaining work on their return All this, however, quite fails to meet the situation

Special organizations are necessary, which should, in fact, perform the function of lay auxiliaries to the asylums Such societies should have a temporary home, where a patient without family or friends could go immediately on leaving the asylum, so that he would find himself at once in an atmosphere of friendly encouragement He should be aided to find work, and to regain the habit of independence which is too often permanently lost in the asylum If the patient had been an alcoholic, great pains might be necessary to prevent a return to his former associations and a relapse into his former indulgence The functions of such a society, however, must go still further It should concern itself with such matters as the humane care of patients during the period when they are in custody awaiting inquiry as to their mental state, it should combat the popular ignorance and dread of the asylum, and above all, should aid in popularizing the knowledge that acute and transitory cases should have immediate care under surroundings so closely approximating those of the general hospital that the old asylum stigma would be lost Such societies should have the right of entry to public institutions, as have the valuable State Charities Aid Societies of New York and New Jersey They would undoubtedly succeed in greatly improving the condition of the insane under county care in the various states

The creation of societies for the aid of discharged patients would have many foreign precedents In Germany, for instance, there are fifteen volunteer societies organized for the aid of the insane, the first of which was begun in 1842 In general terms, their purpose is "To give moral and material assistance to indigent, discharged patients in order to facilitate their return into society and to prevent a recurrence of their malady" "To improve the public care of the insane, and to combat the popular prejudice against the insane and against asylums" In the organization of these German societies the initiative has been taken by medical men, and usually by the physicians in charge of the regional asylums Physicians are members, and aid in directing the work, though the majority of the members are, of course, non-professional Persons can become members on annual payment of a small fee, or by lending their personal aid in caring for individual cases The reports show that considerable sums of money are disbursed, and indicate that the societies have large memberships and perform a most useful work

There are similar societies in other continental countries In Paris there are at least two *Societes de Patronage des Alienes* There is no doubt that such organizations would prove even more useful in America than abroad, and, if once started under wise auspices, there can be no question of their successful appeal to public sympathy

NATURAL AND ARTIFICIAL ANTHRAX IMMUNITY

The study of immunity and susceptibility to disease by test-tube experiments, has brought to light a number of seemingly paradoxical results It has been shown for instance, that human blood serum is strongly bactericidal *in vitro* for typhoid and dysentery bacilli and that it may retain this property, although sometimes in a less degree, during the course of these diseases Chickens and swine are practically immune to anthrax infection, and yet it is found that the blood and the blood serum of these animals form good culture media for anthrax bacilli Dogs also are relatively immune, and their blood likewise is a good nutritive medium for this form of micro-organism Rabbits, on the other hand, are very susceptible to anthrax infection, while their extravascular blood serum almost instantly kills large numbers of the bacilli Cattle and sheep are susceptible to anthrax, and their blood serum also forms good culture medium, but it has been shown that this serum contains a large amount of amboceptor which, with a suitable complement, may take part in the destruction of the bacilli These experiments therefore do not give us the slightest hint as to why one animal is susceptible to a certain infection and another is immune to it They show that the results obtained by test-tube experimentation do not necessarily give us any information regarding that which takes place in the animal body

It has often been the aim of investigators to make the test-tube experiments as simple as possible This simplicity is doubtless a desirable thing, but necessarily produces a set of conditions entirely different from that encountered in the animal body, and the results thus obtained must accordingly be of little value in giving us an insight into the processes going on in the animal organism Recognizing this fact, Bail and Petterson[1] have made a series of experiments in which they attempted to approximate the conditions that are found in the body, and the results thus obtained are entirely different from those obtained by the simpler experiments They have shown that rabbit serum which is anthracidal *in vitro* is deprived of that property by the addition of only a small quantity of an emulsion of organ cells, such as liver, spleen, bone-marrow, etc This seems to be due to the fact that the organ cells have a greater affinity for the amboceptors of the serum than have the anthrax bacilli, thus taking them away from the latter In the small capillaries of the living organs the amboceptors may likewise be bound to the organ cells, and thus be prevented from taking part in the destruction of the bacilli that have reached the organs This seems to be a satisfactory explanation of the susceptibility of rabbits to anthrax infection, in spite of the fact that their extravascular blood serum is strongly anthracidal Chickens are practically immune, although their extravascular blood serum possesses no anthracidal powers It does, however, contain amboceptors as is shown by the fact that it can be made active by a very small quantity of rabbit serum If, now, normal chicken serum is mixed with bone-marrow or with leucocytes, it at once becomes anthracidal Beef, goat and swine serums also may be made active by the addition of chicken's bone-marrow Bail and Petterson conclude from this observation that the bone-marrow and leucocytes of the chicken contain a complement which, acting conjointly with the amboceptors in the serum, destroys anthrax bacilli, and thus protects chickens against infection Dog serum with leucocytes or bone-marrow also has anthracidal powers, thus explaining the relative immunity of dogs The leucocytes and bone-marrow seem to be capable of giving off small quantities of complement to the serum, as is shown by the fact that the serum is slightly anthracidal when obtained twenty-four hours after the intravenous injection of a large dose of anthrax bacilli, also by the fact that the cell-free exudate obtained from the pleura of a rabbit dead from an intrapleural injection of anthrax is capable of activating dog, sheep or hog serums None of these serums is anthracidal nor is the cell-free exudate when used alone

Bail and Petterson immunized young dogs and chickens by repeated injections of anthrax bacilli until these animals could stand about ten times the ordinary fatal dose (Young dogs are more susceptible to anthrax infection than older ones) They then studied the organs and body fluids of these animals to determine the change produced in them during the process of immunization The blood serum, in no instance, had acquired anthracidal powers, but it was found that the defibrinated blood was capable of destroying the bacilli This anthracidal power of the blood was shown to be proportional to the number of leucocytes contained in it, and these were greatly increased by the injections of anthrax bacilli The mixture of serum and bone-marrow had acquired a much higher anthracidal power than a similar mixture from a normal dog of the same age The investigators could not detect an increase of amboceptors in the serum but believe that there was an increase in complement, because there was a marked increase in the leucocytes, and these they believe contain the complement These experiments show very nicely the great complexity of the phenomena of infection and immunity and also emphasize again the important part played by the leucocytes in protecting the body against bacterial invasion

EUTHANASIA FOR THE DEFECTIVE AND INCURABLE

Every little while some enthusiastic or notoriety-seeking writer bobs up advocating the curtailing of human existence in hopeless and incurable cases The idea of the sacredness of human life is hardly sufficiently installed in such people's intellect, hence these lucubrations Moreover, it is apparently a belief of many of the laity that physicians do assist hopeless cases out of the world Not long since a writer in a daily paper speaking as an ex-mayor of a large city, told of a case of this kind, admitted by the physician and claimed to be justifiable, which he was forced to investigate He says he consulted the best physicians in the city, and that they justified the act We doubt this statement throughout We do not believe that any number of physicians in any city would express such an opinion It is directly contrary to the spirit of the profession and it is certainly unfortunate that one writing as a municipal reformer should be willing to publish such a statement

Now comes the announcement that a French professor is advocating premature euthanasia for incurables and the establishment of death rooms in hospitals where hopeless patients, at their own volition, may be painlessly sent out of the world Such publications are dangerous as tending to diminish the respect for human life which should prevail in any civilized community as directly encouraging homicide, and as unpardonable as any other form of murder

We may excuse the person who commits suicide to avoid inevitable torture or dishonor, but we can not justify in any way the physician who deliberately cuts short his patient's existence under any conditions whatever. It is his business to prolong, not to curtail human life, and under no circumstances whatever can he alter this rule. For professional reasons, altogether apart from those of public policy which would also prohibit such taking of human life under any circumstances, a physician should be the last of all men to advocate or excuse it. Death rooms in hospitals for the purpose proposed would be about as respectable as suicide clubs.

PATENT MEDICINES CONTAINING ALCOHOL BARRED IN SOUTH CAROLINA

According to the South Carolina newspapers, they are taking effective action regarding certain "patent medicines" that it might be well for other states to follow. Probably it is because South Carolina through its dispensary law controls the sale of alcoholic liquors that it is able to do what it seems to be doing. One paper speaks of drug stores being prohibited from selling peruna on account of the alcohol it contains, and that hereafter it can be had only on the prescription of a physician. Another shows that it is not only peruna that is barred, but Hostetter's bitters, De Witt's stomach bitters and some others less known because less advertised. According to the state chemist's analysis Hostetter's bitters contains 41.3 per cent., De Witt's stomach bitters 37.6 per cent., and peruna 26 per cent. of alcohol, and consequently are to be classified as intoxicants.

CARBOLIC ACID AND ITS DANGER.

Carbolic acid has long been regarded as a harmless chemical and as such forms part of the domestic equipment of many homes. Its dangers, however, are coming to be appreciated. We have learned that even in dilute solution it may cause serious lesions and its lethal possibilities are recognized by an increasing number of would-be suicides. It is on account of this last named fact that the health authorities of New York City have, it is reported, made a regulation requiring the registration of all sales of carbolic acid of strength above a 5 per cent. solution. This is a measure which can be commended and should have been adopted before. It is to be hoped that the example will be followed in other communities. It is rather a curious fact that suicides often choose most repulsive and uncomfortable methods, and this may account for the preference in so many cases for carbolic acid, which can hardly be considered an agreeable method. Be this, however, as it may, the chances of accidents from the common domestic use of this poison are of themselves sufficient to justify restrictions of its sale.

NERVOUSNESS IN SCHOOL CHILDREN

According to statistics, reported in the daily press one in three of the school children of the city of Chicago is affected with some form of nervous disorder showing itself usually in the form of sluggishness and mental depression with melancholic tendencies or by some degree of choreic manifestations. The causes alleged are the strenuous city life, the impure atmosphere of dwellings, the bringing up of children in flat buildings with deficient facilities for exercise, light and ventilation, the constant noise, day and night, and late hours and lack of sufficient sleep and nutrition. Beside the danger of overdevotion to study, city children are subject to excitements and social temptations to which those in smaller communities are far less liable. The introduction of manual exercises in schools will prove remedial to some extent, but it seems from the list of alleged causes that some of them are almost irremediable. The urban tendencies of population at the present time are not favorable to the production of a robust race, and any sanitary measure that will counteract this tendency should be encouraged. It may be that a special city type of mankind will be evolved; we fear a more or less defective or degenerate one. In the meantime we will have to go on enlarging and multiplying our asylums for the defective and the insane, and recruit as heretofore the best blood from the country.

COMMISSIONS ON PRESCRIPTIONS

A Philadelphia chemical company is trying to corrupt those of our profession who may be corruptible by the old scheme—for it has been tried several times before without success—of offering commissions on prescriptions in the shape of shares of stock in the company. "A credit will be allowed, equal to 25 per cent. of the wholesale price of the prescriptions prescribed, redeemable in stock of the company." The company in its booklet assures the reader that the concern "is strictly a co-operative pharmaceutical house, owned, controlled and operated in the interest of the profession. Ninety-five per cent. of the stockholders are medical men, and no stock will be sold or disposed of except to members of the medical profession and doctors of dental surgery." This certainly will reassure anyone who may have any doubts as to the ethical nature of the scheme. Positively no stock-exchange operators or other gamblers will be allowed to get within reach of this plum, whose stock is so valuable "that only a reasonably short time will elapse before the company will be able to pay dividends equal to the par value of the stock." Each physician is supplied with a book of blanks, wherein he is to enter, day by day, opposite the name of each preparation of the company, the amount he has that day prescribed. Once a month he is to send in this drummer's sheet and secure his rake-off. The prospectus does not say so, but we suppose that those who sell the most goods will be put on a regular salary basis and be considered regular drummers for the house. There is one sign of conscience about the managers of this scheme—they doubtless fear that some practitioners may prescribe the company's goods without proper discretion and increase their commissions without due regard for the welfare of the patients. The following statement appears, therefore, in conclusion: "You should make yourself acquainted with the formulas and uses of the preparations and prescribe them whenever you believe they will be as efficacious as those of any other manufacture."

THE BACTERIOLOGIC DIAGNOSIS OF DIPHTHERIA

While the specificity of diphtheria and the diphtheria-bacillus is universally admitted, it is recognized that, on the one hand, membranous deposits may form in the air passages from other causes, while, on the other hand, the bacillus may be present in association with catarrhal manifestations alone or even without other evidences of diphtheria. Diphtheria-bacilli have been found also in the throats of persons suffering from other diseases, scarlet fever especially. In order to clear up some of the mooted points in connection with the presence and the pathogenicity of diphtheria-bacilli, Dr. B. Czerno-Schwarz[1] made a study of the nasal and pharyngeal secretion from the patients admitted to the department for contagious diseases at the Wladimir Children's Hospital of Moscow. Of 385 patients received into the division for cases of scarlet fever and measles, 45 (11.6 per cent.) yielded, on first examination, a growth of diphtheria-bacilli, divided as follows: Eight of 207 cases of scarlet fever, 3.6 per cent., 37 of 160 cases of measles, 21.92 per cent. Of the former patients, seven presented necrobiotic angina and one follicular angina, while of the latter only two presented symptoms of diphtheria. As a result of the observations made, the conclusion is reached that negative results from repeated examination for the presence of diphtheria-bacilli are of undoubted and absolute value. By this means it has been demonstrated that membranous angina, laryngitis and croup may be of non-diphtheric origin. The significance of positive results from bacteriologic examination is likewise undoubted when the clinical picture is that of diphtheria. When, however, there is a discrepancy between the clinical picture and the results of bacteriologic examination the diagnosis must be considered as doubtful.

FIBRINOUS BRONCHITIS

Fibrinous bronchitis is a rare disorder, probably of diverse etiology. The diagnostic feature is the expectoration of casts of the bronchial tree, of varied shape and length, in conjunction with a sense of suffocation, cyanosis, shallow and frequent respirations, enfeebled respiratory murmur, and unaltered percussion-resonance unless the alveoli become occluded or atelectasis develops. The symptoms disappear temporarily with the expectoration of the coagula, to return on their re-formation. There has been some difference of opinion as to whether the casts consist of fibrin or of mucus, the one substance being found in some instances and the other substance in other instances. From all of the evidence, however, it would appear as if both substances are often present, sometimes together, sometimes alone. Confirmation of this view is afforded by a communication recently made by Dr. Gustav Liebermeister,[2] who reports in detail a case of fibrinous bronchitis, and also gives the results of a study of the casts obtained from twelve other cases of similar kind. He found that the coagula expelled in a case of grave heart disease during the death agony differed only in their great thickness from the casts expelled in cases of true fibrinous bronchitis, although they agree chemically and histologically. Idiopathic fibrinous bronchitis is to be strictly differentiated, with reference to both the etiology and the morphology of the coagula, from descending diphtheria and from diphtheria of the bronchial tubes without involvement of the larynx. The coagula of true fibrinous bronchitis are honeycombed in structure, more or less completely filling the lumen of the bronchial tubes and generally containing a moderate amount of air. Microscopically the appearances presented are those of a reticular structure, consisting of fibrin and mucus, and having spaces containing few cells. Fibrin was demonstrable in the casts in all of the cases and mucus also in seven. In cases of descending diphtheria, structures analogous to the deposits on the tonsils and the larynx are formed in the bronchi. These consist of a dense compact, finely fibrillated fibrinous network, containing enormous numbers of cells, and they appear as simple or dendritic cylindrical membranes that can be detached from the mucous membrane surface only with the loss of epithelium. Curschmann's spirals were found in only one case among thirteen. The presence of Charcot-Leyden crystals and of eosinophile cells in the casts could not be demonstrated in any case.

THE SPECIFICITY OF THE BODY CELL TOXINS

The observation that the blood of one species of animal is toxic to members of another species is an old one, and the modern studies set on foot by the work of Bordet and others have greatly extended our conception of body-cell toxicity, and have shown that it is not confined to blood cells alone. It appears at first sight such a simple matter to inject a particular cell or organ from one species of animal into a member of another species, that this line of research has been extensively followed in the last year or two. Then the results achieved in some instances by this work have illuminated some of the dark regions of pathology, and further research has seemed likely to give good results. It has been pretty generally assumed by the workers along these lines that a cell specificity existed, i. e., that if an animal is injected with ciliated epithelium it will produce antibodies for ciliated epithelium only, but it seems probable that this presumed specificity has been greatly overestimated. This whole question of specificity has recently been investigated by Pearce.[1] As Pearce indirectly brings out, many of the previous investigators seem to have assumed that morphologically similar cells would give rise to similar antibodies. Pearce's work had for its object to demonstrate that the chemical composition of the cell and not its morphology is the factor determining its specificity of action. He likewise endeavored to show that many of the results supposedly due to the specific action of one cytotoxin are really due to other cytotoxins adventitiously elaborated as the result of improper methods of immunization. As a result of his observations, Pearce concludes that the cells of the various organs of the body while differing in morphology and function have certain receptor characteristics in common, and that one type of cell may therefore produce antibodies affecting several cell groups of differing morphology, but with like receptor groups He also concludes, from comparing results obtained with organs as ordinarily removed with those obtained with organs freed from blood, that many of the positive results described as specific are due, not to specific action of the particular cell or organ used, but rather to the blood introduced with them It would seem, therefore, that not a little of the published work on cytotoxins is valueless on account of mistakes in technic, and that much of the valuable work has been misinterpreted This means that a great deal of research must be done over again by the more careful methods suggested by this study

Medical News.

ILLINOIS

Personal.—Dr Anna E Blount, Oak Park, has returned after a year in Europe——Dr Pliny W Blanchard is seriously ill at his home in Harvard.

Smallpox.—The smallpox situation at Belleville is causing grave anxiety, and the authorities are taking all possible precautions to limit the spread of the disease——Dr John J Leahy, Lemont, who claimed $5,750 for services during a smallpox epidemic, was *allowed $5,000 in full of all claims*

Copper as a Germicide—The State Board of Health is conducting investigations to determine whether water with typhoid fever or cholera germs can be purified simply by being kept in copper containers for a few hours The experiments are being made under the direction of Dr John H Long of the Northwestern University Medical School

Chicago

Smallpox.—During the week 5 cases were sent to the isolation hospital Two unvaccinated children died at the hospital

Thousands for Hospital.—At the annual benefit concert for the Samaritan Hospital held September 16 $2 000 was realized for the institution

College Lengthens Course—The College of Physicians and Surgeons, the College of Medicine of the University of Illinois, has extended its course to nine months The term opens September 27

Pneumonia Deaths Increase—The deaths from pneumonia for the week ended September 17, were 34, an increase of 15, or nearly 80 per cent over the mortality of the previous week from this cause.

Deaths of the Week.—The total deaths for last week were 143, the same as for the previous week. The increase in pneumonia mortality was more than compensated by the decrease in deaths from the more directly controllable diseases, and notably from those of the intestinal tract, such as acute intestinal diseases and typhoid fever

INDIANA.

Sanitarian Appointed—Dr T Victor Keen has been appointed city sanitarian by the Indianapolis Board of Health. The board will equip a laboratory for the chemical and bacteriologic research work of Dr Keen

Takes Strychnin by Mistake—Dr H. M. Connelly, Shelbyville, who has been in ill health for a long time, recently took strychnin in mistake for other medicine He became violently ill, but his life was saved by prompt medical care

Pre medical Examinations—On September 15 and 16 the State Board of Medical Registration held an examination at Indianapolis of applicants for admission to the medical colleges of the state whose preliminary education had been outside of the regularly accepted sources

IOWA.

Hospital for Poor and Old—A W Buell, Mount Pleasant, has donated a building and grounds of ten acres in that city as a home and hospital for the aged

Physician Re located—Dr Alonzo E Rodgers, formerly of Stanhope, who was confined in the Tipton jail for several months on a charge of forgery, which at the trial was shown to have occurred through a misunderstanding, has been released and will practice at Homer

Jury Trial for Inebriates.—On the completion of the new state hospital for dipsomaniacs at Knoxville, the authority to hear and pass on cases of dipsomania will be taken from judges, and in each such case a jury will decide whether or not the individual is a fit subject for commitment to the hospital

New Rules for Diphtheria Quarantine.—The State Board of Health has promulgated the following rules regarding the quarantine limit after diphtheria

> Quarantine shall be released in those houses in which diphtheria has been diagnosed when synchronous cultures taken from the noses and throats of all infected persons quarantined show two consecutive negative examinations providing the regulation of the board regarding disinfection and fumigation have first been complied with.
>
> Those who have been quarantined with diphtheria patients may be released from quarantine when both nose and throat cultures on examination by a bacteriologist of the state board of health do not show the presence of diphtheria bacilli
>
> In districts where it is not possible or desired to use the laboratory findings as a means of regulating quarantine, those suffering from diphtheria shall be quarantined for a period of not less than four weeks for initial symptoms where antitoxin is used and five weeks where antitoxin is not used

LOUISIANA

Generous Donation for Italian Hospital.—Capt Salvatore Pizzati, New Orleans, has given $250,000 as the nucleus of a fund for the establishment of a hospital for Italians in New Orleans

Medical Student Dies.—Emile Hussey, New Orleans, a medical student at Tulane University, died September 1, as a result of *injuries to the spinal cord received while diving into shallow* water at Bay St Louis, in July last

Health Board Matters.—The St Bernard Board of Health assembled, September 6, and organized with Dr Louis E Fondruat as *chairman and ex officio* health officer——On September 6 Drs J A. Harper, J F Polk, and Phau R. Outlaw were elected members of the Slidell Board of Health.

MARYLAND

Faculty Honors Osler—The Medical and Chirurgical Faculty of Maryland, at its semi annual meeting in Ocean City, September 9, authorized the president to appoint a committee to take marked action in regard to the departure from the state of Dr William Osler A portrait of Dr Osler is to be painted and placed in the hall of the faculty in Baltimore.

Personal.—Dr Herbert L Rich, of the science department of Western Maryland College, has been made a resident physician of the Jacob Tome Institute, Port Deposit——Dr J B Schwatka returned from Europe September 16——Dr Herman Bruelle has gone on a southern trip, and will visit Fredericksburg——Dr William Hewson Baltzell will spend the winter in Rome

Baltimore

Lowered Mortality—The mortality rate last week was at the annual rate of 15 48 per 1 000, viz white, 14 00, colored, 23 52, for the previous week the respective rates were 20 47, 16 95, and 39 62 per 1,000

College Opens.—The course at the College of Physicians and Surgeons will open the evening of September 30, with an address by Prof Wm Royal Stokes, who will speak on "Some of the Great Achievements of the Last Century"

MASSACHUSETTS

Surgical Building Offered.—The Brockton Hospital Corporation has accepted a surgical building donated by Hon. William L. Douglass, to cost $22,000

Alleged Counterfeiter Held.—Dr Frank Sanft, at whose house in Roxbury $10,000 in counterfeit money was found, has been held to the grand jury

Hospital Building Permit Granted.—Permission has been granted to the Waltham Hospital Association to build a two story concrete building, to cost $25,000

Member Expelled—Dr George S Hatch, Boston, formerly of Pittsfield, and now a fugitive from justice, was expelled from the Berkshire District Medical Society at its meeting last month

Imprisoned for Refusing Vaccination—A resident of North Adams is serving a sentence of eight days in the House of Correction for refusing to be vaccinated. He will not only have to serve out his time, but, in accordance with the rule of the institution, must be vaccinated.

Personal—Dr Charles G Stearns Lancaster has retired on account of impaired health ——Dr Nathaniel Wallis, Fitchburg, will soon start for Australia ——Dr Julian D Lucas, Chelsea, has been made assistant to the medical officer of the port of Boston ——Dr William L Smith, Worcester, has been appointed honorary physician to the Shah of Persia.——Dr John A Bruce Everett is taking a four months' tour of Europe

MICHIGAN

Fire Loss—At a fire which at one time threatened to destroy all the business section of North Branch the office of Dr Albert E Weed, with its contents, was entirely consumed No insurance was carried

Pre-Medical Examination—The examination for entrance to Michigan medical colleges, for students who have not received diplomas from high schools or colleges, was held in Detroit, September 14 and 15, under the direction of the Michigan State Board of Registration in Medicine

The Most Dangerous Communicable Diseases—Meningitis was reported during August at 7 places, whooping cough at 24 places, pneumonia at 26 places, measles at 38 places, diphtheria at 66 places, scarlet fever at 74 places, smallpox at 106 places, typhoid fever at 161 places, and consumption at 295 places Meningitis was reported at 1 place less, whooping cough at 10 places more, pneumonia at 6 places more, measles at 35 places less, diphtheria at 9 places more, scarlet fever at 4 places more, smallpox at 10 places less, typhoid fever at 88 places more, and consumption at 7 places more in August than in July

Comparative Disease Prevalence—For August, 1904, compared with the average for August in the last 10 years, pleuritis, smallpox and diphtheria were more than usually prevalent, and cholera infantum, dysentery, intermittent fever, erysipelas, remittent fever, whooping cough, pneumonia, measles, and inflammation of brain were less than usually prevalent This lessened prevalence was probably due, in great part, to the lower than average temperature during the month So far this year, in Michigan the average temperature each month has been lower than the average for the ten years preceding

August Mortality of Michigan—There were 2,593 deaths during August, 83 more than in the previous month The death rate was 12 1 per 1,000 population By ages there were 576 deaths of infants under 1 year of age, 199 deaths of children aged 1 to 4 years, and 677 deaths of persons aged 65 years and over Important causes of death were as follows Tuberculosis, 190, typhoid fever, 41, diphtheria, 20, scarlet fever, 7, measles, 3, whooping cough, 7, pneumonia, 56, diarrheal diseases, under 2 years, 331, meningitis, 29, cancer, 134, and accidents and violence, 203 The mortality from typhoid fever and diarrheal diseases showed the customary seasonal increase

MISSOURI

Medical Schools Open—University Medical College, Kansas City held its opening exercises September 6, and Central Medical College and Ensworth Medical College, St Joseph, September 15

Gift to Hospital Fund—The St Joseph's Orphan Society, a charitable organization of Jefferson City, has given all its assets, amounting to $2,298, to the new hospital of the Sisters of St Mary, now being erected at Jefferson City, at a cost of $75,000

Epidemic at Wien—An infectious disease resembling tropical dysentery has been raging for six weeks among the children of Wien, Chariton County Fifteen children have died, and many are seriously ill The State Board of Health is making a strict investigation into the nature of the disease

Personal.—Drs Frank L Whelpley and William J Loler have been appointed assistant physicians at the St Louis Insane Asylum ——Dr Joseph F Robinson has been re elected superintendent of State Hospital for the Insane No 3, Nevada ——Dr F L Sutton, Sedalia, has returned after an absence of a year on account of ill health and has resumed practice ——Dr John R A Crossland, St Joseph, was recently shot in the course of an altercation with a brother practitioner He will recover

NEW YORK.

Personal.—Dr Wallace Clarke, Utica, has been appointed by the State Commissioners of Health a smallpox expert in his department ——Dr Clarence A Potter Gowanda, has been appointed first assistant physician at the Gowanda State Hospital

Buffalo

Personal—Dr Charles G Stockton has returned from Europe ——Dr Emil S Tobie will soon sail for Europe ——Dr John Hauenstein, oldest practitioner in the city, recently celebrated the seventy third anniversary of his arrival in Buffalo ——Dr Francis E Fronczak was re elected general medical examiner of the National Polish Union at its last convention

Vital Statistics of August.—The monthly report of the department of health for August shows an annual death rate of 15 57 per 1,000 The principal causes of death were Consumption, 40, cholera infantum, 67, typhoid fever, 4, debility, 30, cancer, 18, apoplexy, 16, meningitis, 11, valvular heart disease, 2, pneumonia, 17, appendicitis, 9, diarrhea, 15 dysentery, 10, enterocolitis, 15, gastro enteritis, 25, ileocolitis, 10, nephritis, 14, and violence, 31 The total deaths for August were 487, as compared with 538 deaths for August 1903

Scarlet Fever from Infected Milk.—An epidemic of scarlet fever has occurred which is directly attributable to milk supplied to the families This milk is supplied by the Certified Milk Company from dairies in Elma Two years ago these dairies were inspected by a number of Buffalo physicians, who refused to certify that the milk as then handled was cleanly In this present epidemic it has been found that the daughters of the man who milks the cows has scarlet fever, and that the son of the proprietor of the dairy also had the disease The health authorities have stopped the further supply of milk from this source and reported the matter to the State Department of Health, which has jurisdiction State Health Inspector Dr Johnson of Albany has arrived to make an investigation of the scarlet fever epidemic Dr Henry R Hopkins, in an open letter to the Buffalo *Express*, holds the health commissioner to blame in that he allowed the sale of infected milk when the milk register inaugurated by the former health commissioner showed a number of scarlet fever cases on the milk route of the Certified Milk Company It is deplorable that the health officer of Elma did not stop the supply of milk from the infected dairy at Elma as soon as he knew that scarlet fever existed on the premises One death has already occurred, it is claimed, as a result of this infection, that of Mrs Sicard A further epidemic of scarlet fever in which 10 cases have already occurred has been traced to the milk supplied by another dairy The sale of this milk has been promptly stopped by the health department

New York City

Pasteurized Milk Stations Closed—The summer season of Nathan Straus' pasteurized milk depots has closed During the summer 2,149,194 bottles were distributed, and more than 800,000 glasses of milk were sold in the parks and recreation piers

Bellevue Doctors Want Men Servants—The president of Bellevue Hospital Medical Board recently issued an order that hereafter women should be employed as servants for the hospital internes The 44 physicians and surgeons interested have made a formal protest asking the president to revoke his order

Better Pay at Bellevue—To obtain better service from a better class of men, the pay of orderlies at Bellevue Hospital has been raised to $30 per month, and each will be held strictly accountable for the accuracy of his work It is hoped that this will do away with many complaints of ill treatment at this institution

Contagious Diseases—In the week ended September 12 there were reported 391 cases of tuberculosis, with 139 deaths, 176 cases of diphtheria, with 25 deaths, 146 cases of typhoid fever, with 21 deaths, 60 cases of scarlet fever, with 2 deaths, 40 cases of measles, with 8 deaths, 2 cases of varicella and 1 deaths from cerebrospinal meningitis

Personal—Dr Alexander Lambert has gone to Canada moose hunting ——Dr James R. Healy has recently undergone a serious operation at Roosevelt Hospital, and is now convalescing ——Dr H Holbrook Curtis arrived from Europe September 17 ——Dr Follen Cabot, Jr, has been appointed genito urinary surgeon to the City (Charity) Hospital

Bequests—Under the will of the late Solomon Gerber the Lebanon Hospital and the Home for Aged and Infirm Hebrews each received a bequest of $250 ——Under Dr Henry Tuck's will the New York Society for the Relief of Widows and

Orphans of Medical Men of New York City, the Society for the Prevention of Cruelty to Children and the New York Charities Organization Society were the recipients of generous legacies

Begin to Fight Trachoma—The board of health inspectors have begun the work of examining the eyes of all school children for trachoma Every child affected with the disease is kept from school until *an operation* has been performed or treatment initiated A new trachoma hospital has been opened where the operations will be performed by the department free of charge

Physicians' Aid Association Prosperous—The recent report of the New York Physicians' Mutual Aid Association, now in its thirty fifth year, shows the organization to be in a very prosperous condition, with a membership of nearly 2,000 The association has on hand a permanent fund of nearly $50,000 Much good has been done in relieving its members during periods of illness, and in paying the families of deceased members $1,000 each

Cornell University Medical College.—Dr Frederick Whiting has been appointed professor of otology vice Dr Gorham Bacon, resigned——Dr Adolf Meyer *has been appointed* professor of psychiatry vice Dr Allan McLane Hamilton, resigned——Many students are registered for the coming first year class to begin work on September 28 The campaign carried on so vigorously in the medical press for better preliminary education is beginning to bear fruit, for 78 per cent of those applying present evidence of having studied chemistry and physics

Druggists Protest—Committees of druggists have been appointed to wait on Commissioner Darlington and ask him to rescind or modify his recent ruling that pure carbolic acid must not be sold except on the presentation of an *order from* a licensed physician The druggists claim that the health department is usurping the functions of the State Board of *Pharmacy* by *amending* the sanitary code so as to regulate the sale of poisons This move is also viewed with alarm because it can not be seen where the commission may stop If it is permitted to discriminate in regard to carbolic *acid there* would be nothing to prevent its making regulations in regard to the sale of opium, morphin, cocain or even whiskey or beer

PENNSYLVANIA

Nominated for Congress—Dr Salem Heilman, Sharon, has been nominated as Democratic candidate for congress

Personal.—*Dr George D Morton,* Moores has been named a member of the board of health vice Dr A C H Schneider, deceased

New Staff Members at Reading Hospital.—Dr Harry F Rentschler *has been made assistant* physician, vice Dr John Shartle, resigned——Dr Frank G Runyeon has been nominated as assistant to Dr William S Bertolet——Drs Fred L R Mattern and George W Overholser were made assistant physicians

Charged with Illegal Practice—Drs Joseph C Denston Emilie D'Antonio and Guiseppe Villone Scranton, have had warrants issued *for their arrest on the charge that they* violated the act of 1893, which provides that every physician practicing medicine in Pennsylvania shall have a certificate from the State Board of Examiners and that this certificate shall be shown to the prothonotary of each county, who shall register the physician

Philadelphia

Bequest.—By the terms of the will of Amos Wert $5,000 is given to the Methodist Hospital to provide a free bed to be known as the "Wert bed"

Physician Robbed—Dr Berthold Trautmann's residence was entered by burglars, September 13, who secured a large amount of clothing, a watch and a moderate sum of money

Personal.—Dr and Mrs Donnell Hughes, Dr and Mrs George C Stout and Dr and Mrs Charles P Noble, have returned home after spending the summer in Europe——Dr W L Rodman has removed his residence and office to 1904 Chestnut Street

Germantown Hospital—The new building of the Germantown Hospital for the treatment of private patients has been completed and was opened for inspection September 12 The building is a three story brick and stone structure and has accommodations for 25 patients

Pink Eye Prevalent—An epidemic of pink eye prevails in the northwestern part of the city, particularly among school children. On account of the highly contagious *character* of the disease, medical inspectors from the Bureau of Health have been detailed to inspect the schools and suspend all afflicted children

Work at Hospitals.—In the Presbyterian *Hospital* 405 patients were admitted and treated during August In the dispensary 2,744 patients were treated——Thirty four patients were admitted to the Howard Hospital and 1,033 were treated in the dispensary——Sixty patients were admitted to St Timothy's Memorial Hospital, and 161 were treated in the out patient service

Health Report—The prevalence of typhoid fever shows no abatement, the report for the week shows the presence of 134 cases, an increase of 34 over the previous week, with 15 deaths, an increase of one over the preceding week There are only *four* wards in which no new cases were reported The total number of deaths for the week was 408, an increase of 8 over last week, and a decrease of 10 compared with the corresponding period of 1903 In all there were 234 *cases of contagious* disease reported, an increase of 20 over last week

Work of City's Bacteriologic Department—Since the establishment of the bacteriologic laboratory in 1897, 32,878 Widal examinations have been made, *representing 28,375* cases of typhoid fever Statistics show that in 1894 when the use of antitoxin went into effect, 33 3 per cent of the cases of diphtheria *reported* to the Bureau were fatal Since the use of the agent has become more general in the city, the mortality is much lower Last year a mortality of only 17 1 per cent was reported Since 1896 there have been 38,981 doses of antitoxin distributed by the city The milk report of the department for July and August of this year, shows that in July 15,447 quarts were examined, 8,679 quarts were condemned, and 5,958 quarts were *infected* In August 194 581 quarts were examined, 6,400 quarts were condemned and 3,449 quarts were infected, making a total of 352,028 quarts examined, 15,079 quarts condemned, and 9,407 quarts infected

GENERAL

Typhoid in Winnipeg.—The number of typhoid patients in the Winnipeg (Man) General Hospital one week ago numbered 130

Panama Canal Hospital.—New Orleans is to be the site of a hospital built by the United States Government for Panama Canal patients

Lack of Poor Physicians in Hawaii—It is stated that the reduction in the force of government physicians in Hawaii has caused a return on the part of many natives to the witch doctors and that the death rate is increasing

The Dental Congress.—At the Fourth International Dental Congress held at St Louis, September 1, a gold medal was offered for the best paper Ten papers were submitted Willoughby D Miller, Berlin, Germany, received the medal, and Eugene S Talbot, Chicago, received honorable mention for the second and third best papers

Foreign Visitors.—Among the noted medical men from *abroad* who are speakers at the International Congress of Arts and Science at St Louis are *Dr Ronald Ross*, Liverpool, Dr Shibasaburo Kitasato, Tokio, Japan, and Dr Theodore Escherich, Vienna Dr Ross, the great authority on malaria, will visit Panama and Jamaica before returning to Europe. While Dr Escherich was in Albany, N Y, a reception was given in his honor by Drs Henry L K Shaw and Andrew McFarlane, September 12, and on the following evening Dr Albert Vander Veer gave a dinner in his honor at the Fort Orange Club In Chicago, Dr Escherich addressed the Chicago Medical and Chicago Pediatric societies, and was given a banquet He also made an address in the amphitheater of Cook County Hospital While in Chicago he was the guest of Dr A C Cotton, who gave a *reception in his honor* Dr Kitasato, the famous bacteriologist of Japan, received a very warm *greeting in* Honolulu The Hawaiian Territorial Medical Association gave him a *reception and banquet*, and there were other functions in his honor

THE RECENT ARMY MANEUVERS

Field Practice for the Army Medical Department

(*From our Special Correspondent*)

The recent maneuvers in Virginia have attracted much public interest, both because the number of troops participating was far larger than has ever before been assembled in this country in time of peace for such a purpose, and because the extensive area covered by them embraced the historic fields of the first and second battles of Bull Run

The operations of the medical department of the two maneuver divisions, the 'Blues" and 'Browns," which together mustered 26,000 men, presented several features of interest The medical organization comprised the regimental dispensaries, field hospitals, and a base hospital for each army The function of the regimental dispensaries was to render first aid on the march and in battle and to treat in camp the mild cases which did not require transfer to the base hospitals The personnel of these was, for the state troops, furnished by their own medical officers and hospital corps men, and they brought with them the medical equipment furnished by their respective states Many of the regiments had the new U S Army regimental field chests and pouches recently issued to the states under the provisions of the Dick militia bill while, in the case of others, the medical equipment was more or less obsolete or wanting Some regiments brought surgeons, but no hospital corps men "broom handles but no brooms" There were two field hospitals and two ambulance companies for each army These were manned and equipped, as were the base hospitals by the Medical Department of the Regular Army although surgeons and hospital corps men were taken from such militia regiments as could spare them, and attached to these organizations for purposes of instruction and to fill up as far as possible their shortages in personnel

The field hospitals are mobile organizations, which march with the troops, there being theoretically one for each brigade Their function is to give temporary care and shelter to the wounded after battles until they can be transferred to a stationary or base hospital, where can be found the rest and elaborate equipment which field hospitals can not afford

The ambulance company is in battle the connecting link between the regimental dressing stations on the line of battle and the field hospital in the rear The widely extended order of modern tactics and the great range of rifles and artillery make this gap a broad one and the duties of the bearers and ambulances correspondingly arduous In these maneuvers the labors of the ambulance companies were, however, much lightened by the military ardor of the soldiers designated to play the part of the wounded, for these, being unwilling to leave the exciting scenes at the front, in most cases concealed their tags in their pockets or dropped them behind a convenient bush and remained in action But though wounded were lacking there were abundant applicants for seats in the ambulances on the part of the undeveloped youths whose strength was not equal to the burden of the blanket roll, rifle and haversack, and who strewed the roadsides during the first maneuver Later these were left to guard the camps

The two base hospitals at Thoroughfare and Manassas respectively were models of complete equipment and orderly administration These received all serious cases of illness or injury which required treatment in bed Each had the capacity of a field hospital, namely, 108 beds, and while neither was at any time full, several hundred patients were treated in them including some severe cases of injury such as fracture of the femur, ulna, radius and clavicle, and one penetrating gunshot wound of the chest caused by the paper bullet of a rifle blank cartridge The paper bullet usually flies to pieces at the muzzle of the rifle, but in this case the weapon was discharged nearly or actually in contact with the body of the soldier and the conical wad penetrated the blouse, shirt and chest wall in the region of the liver There was severe shock, but under an aseptic occlusive dressing the wound has done well and the patient is expected to recover

These maneuvers have been of the greatest educational value to the medical personnel, beside affording an opportunity to test the medical organization and equipment on a large scale Their value to the state troops would have been vastly increased could they have arrived in camp several days before the beginning of the field operations so as to have had an opportunity to have gained coherence of organization by regimental and brigade drills This would also have afforded time for the instruction of the regimental medical personnel in their duties As, however, the movements began the day after the troops assembled, no time was given for the regimental surgeons to learn their place and function in the scheme of medical organization, and some lack of co ordination was the natural result

FOREIGN

Plague is reported in Paraguay and the sanitary condition are not such as to promise its ready extermination

Italian Hospital Receives Gift—The Italian Hospital in the City of Mexico has received $2,000 from King Victor Emmanuel

European Physicians Studying Yellow Fever in the Americas—The French committee now in Brazil consists of Drs Marchoux, Simoni and Salimbeni Dr G Cocchi is in Mexico for the same purpose, delegated by the Italian government The Associated Press report for the week states that there are only fifteen cases of the disease in all Mexico and half of these are in the hospital at Vera Cruz This is a remarkably favorable showing for the month of September and demonstrates what has been accomplished in the way of preventive sanitation

Cholera in Persia—The *Tribune Med* comments on the fact that one province of Persia, of which Tauris is the capital has remained free from cholera during the epidemic that has been devastating the country The crown prince resides there and his physician was trained in the medical schools of Paris They co operated to prevent the importation of the disease establishing quarantine stations and adopting the measures necessary to stamp out the few cases known to exist Their efforts were successful, and probably for the first time in history a Persian city has passed unharmed through an epidemic of cholera sweeping over the country A St Petersburg exchange states that the disease is still spreading The death in Meschhed numbered 417 between July 26 and August 1 Refugees from this place have carried the disease into Russia and a Cossack regiment at Merw has become infected, 9 deaths in 53 cases being reported among the dead being the troop physician There have also been 9 deaths in 13 cases in the town The shipping on the Caspian and travel on the central Asiatic railroad is under medical inspection

DUBLIN LETTER

Smallpox in Ireland.

Considering how widely distributed smallpox has been in England and Scotland during the past few years Ireland is fortunate in having escaped without any outbreak that could receive the name of epidemic Both Dublin and Belfast had a considerable number of cases last year, but in neither city did the disease spread to any great extent, and the number of deaths was very small This is no doubt due chiefly to the very efficient system of vaccination practiced in Ireland, where neither 'conscientious objectors" nor "antivacs" are known This year, while there is nothing in the nature of an outbreak at any center, several cases of smallpox have been reported from various towns throughout the country In Armagh, a town of seven thousand inhabitants, there have been over twenty cases, while in Drogheda, Monaghan, Castleblayney and Dublin smaller numbers are reported The infection seems to have been imported from Glasgow to Drogheda and Armagh, whence it has spread to the other places mentioned

The Queen's Colleges

The annual reports from the presidents of the Queen's Colleges of Belfast and Cork, which have recently appeared, give evidence of increased activity in both those institutions In Belfast, in particular, advance, during the past few years, has been very rapid Following on the establishment of the Royal Victoria Hospital, and in part as a result of the opportunities it gives for clinical work, the Belfast School of Medicine is now one of the largest in the Kingdom It is stated that the number of students on the roll this year is greater than that of any other school in Ireland, with the exception of the Catholic University School in Dublin, while only two English schools—Cambridge University and Guy's Hospital—exceed it The college in Belfast has recently received special funds to provide for pathologic research and teaching, in the endowment of a Musgrave chair and a Riddel demonstratorship in pathology In none of the Queen's Colleges did the original scheme include a chair of pathology, so that considerable diffi culty has been met in providing for the teaching of that subject, but it has now been successfully coped with in all three colleges Great regret is expressed at the departure from Belfast of Dr Lorrain Smith, who has accepted the chair of pathologic anatomy in the Victoria University of Manchester The president of the Cork College, Sir Rowland Blennerhassett, has, in consequence of ill health, resigned his office He was given this post, for which he was little fitted, a few years ago as a reward of political services, but it occupied only a small share of his time, as he spent most of each year on the continent

Sir Thomas Browne and the Medical Profession

The proposal which is before the public at present to raise a memorial to the author of "Religio Medici" has roused the wrath of Dr Conolly Norman, the well known alienist of this city, and he appears in the columns of the *British Medical Journal* in the character of *advocatus diaboli* Whatever claims Sir Thomas Browne has to the admiration of merely literary people as a great master of English prose, he has no claim whatever says Dr Norman in effect to the respect of the medical profession He is not a great physician since he is neither scientific nor humane For proof of the first of these charges Dr Norman refers to Browne's works and thinks the charges is justified while the second charge is based on his action in the trial of the women Deny and Cullender at Bury in 1664, on the charge of causing fits in children by witchcraft "Sir Thomas Browne of Norwich, the famous physician of his time, was in court and was desired by my lord the chief baron to give his judgment in the case and he declared that he was clearly of opinion that the fits were natural, but heightened by the devil, co operating with the malice of the witches at whose instance he did the villainies" Browne's great influence turned the jury, and the women were condemned Dr Norman thinks that belief of this sort in an educated man—a contemporary of Hobbes, Butler and Locke—deprives him of respect from men of science Many lovers of letters who demand thought as well as expression will thank Dr Norman for his very just depreciation of one of the most over rated persons in the history of literature

Death of Dr Cranny

Yet another of Dublin's best known surgeons has died Within the last twelve months no less than five—Croly Smyly, Meldon, Hayes, Cranny—living within a stone's throw have been removed by death Dr John Joseph Cranny, as a young man, was assistant master in the Rotunda Hospital, but of late years had devoted himself altogether to surgery, and for many years before his death was on the surgical staff of Jervis Street Hospital For some years past he had been in bad health, but his death came nevertheless as a shock to his many friends

---

Queries and Minor Notes.

ANONYMOUS COMMUNICATIONS will not be noticed. Queries for this column must be accompanied by the writer's name and address but the request of the writer not to publish his name will be faithfully observed

CONTRACT PRACTICE

A physician of West Virginia writes us in regard to contract practice and states that he has never been satisfied that it was an altogether ethical practice for a reputable practitioner to engage in This system is much in vogue in my locality and throughout the mining section of our state The company or contract physician at the mines agrees for the sum of 50 cents per month for single men and $1 00 per month for men with families to furnish them the necessary medicines and medical and surgical attention The companies hold back out of the wages of their employes the above-mentioned amounts and turn it over to their physician, less 10 or 20 per cent for collecting He goes on to say that this system might be considered a blessing to a very improvident class of people but I have always thought it was prostituting the practice of the profession too far It seems to me it would be more in keeping with the dignity of our profession to let them call on whom they please when needed and pay accordingly Your opinion in the Queries and Minor Notes column would be appreciated

ANSWER.—From a professional standpoint nothing good can be said for the so-called contract practice to which our correspondent refers. Those who undertake it cheapen the public estimate of our profession In a few instances county societies have adopted by laws against the practice declaring it to be unprofessional conduct It would not be a bad thing for the profession if all county societies would do likewise For the man who undertakes contract practice there is "nothing in it —no future no satisfaction no adequate compensation nothing attractive A strike cuts it short a corporation shares the income without adequate pretext. Analyzed the practice is merely a poorly modified form of health insurance or as our British confrères call it, club practice ' The method outlined above which is the one usually followed, is bad The doctor sells himself cheap the employes get what they pay for—and no more A much better method not so profitable to the corporation nor so degrading to medicine would be the creation of a relief fund by an assessment on the employes collected monthly by the company without charge Then a minimum but fair scale of fees for definite services should be agreed on and the physician paid accordingly each employe to select whomsoever he pleases. Of course in time of epidemics or disaster the assessment would increase and in healthy periods would recede but this could be equalized by an average assessment to cover all conditions It is high time that our profession insisted on the universal adoption in corporation or company practice of some such plan as this, and then see to it that no recognized physician underbids his fellow This is by no means Utopian Some corporations have voluntarily adopted a plan similar to this contributing regularly themselves to the fund and the result has been satisfactory We wish that this matter might be taken up by county societies that are affected

LIQUOR FERRI ALBUMINATI

A correspondent calls attention to an abstract on page 1121 of THE JOURNAL April 26, 1902 in which an author is quoted as saying that the standard liquor ferri albuminati of the Norwegian Pharmacopeia is the best means of administering iron and desires to know the formula and the method for its preparation

ANSWER —There is no formula for this preparation in the Norwegian Pharmacopeia There is a formula in the Danish Pharmacopeia (1893) but it is an exceedingly poor one The latest Swedish Pharmacopeia (1901) gives the following excellent formula Take of by weight in grams

Dried egg albumin	40
Solution sodium hydroxid	5
Solution ferric chlorid (50 per cent)	120
Glycerin	10
Alcohol	100
Cinnamon water alcoholic 10 per cent	150
Aromatic tincture	2
Distilled water to make	1000

The egg albumin is dissolved by shaking in a mixture of 2 grams of the soda solution and 1 000 of water heated to 50 C after standing 24 hours the solution is decanted and strained then warmed to 50 C is slowly poured with constant stirring into a mixture of the ferric chlorid solution and the water The resulting precipitate is collected and washed with tepid water till the washings acidified with nitric acid are only slightly opalescent with silver nitrate allowed to drain and then mixed with 60 of water to which the remaining " grams soda solution has previously been added The mixture is then heated on the water bath to 80 C and allowed to cool when the alcohol cinnamon water and aromatic tincture are added together with water to make 1 000 grams The solution represents 4 per mille iron It must be kept in bottles protected against light

PHYSICIANS CARDS

FREDERICKTOWN OHIO Sept 5 1904

To the Editor —Please inform me through Queries and Minor Notes' the proper form for cards for medical men—not for business but for social purposes

E. V A.

ANSWER —This is wholly a matter of individual taste The following forms are merely suggestive, but are acceptable anywhere

DR JOHN DOE

JAMES JOHNSON M D
2735 INDIANA AVE

DR ALBERT SMITH
65 Pennsylvania Ave NEW YORK CITY

OSCAR O JONES, M.D,
NEW ORLEANS

The above forms are social only Business cards may properly present office and residence addresses, telephone numbers and office hours

EXAMINATION OF MILK.

RADCLIFFE IOWA Sept. 14 1904

To the Editor —Will you please inform me where I can find Babcock's Method of Examination of Milk or state how the percentage of fat is obtained by him?

HANS PETERSEN A B M.D

ANSWER.—Send for eighth Report of the Wisconsin Agricultural Experiment Station Madison, Wis

ABSENCE DOES NOT INVALIDATE LICENSE

De Forest, Wis Sept 10, 1904

To the Editor —I graduated from the College of P and S, Chicago, in 1886, obtained a medical license and practiced part of the same year in Chicago but not since Would the same license permit me to legally practice in Illinois now? J H B

Answer —Yes

Marriages.

Lewis C Dow, M D, to Miss Alice Lillie, both of Marion, Iowa, September 19

William J Awty, M D, Moorhead, Minn to Miss Ethel Ford of Charleston, Ill

Ralph Clinton Cupier, M D, to Miss Isabella Lukin, both of Chicago September 1

C Graham Dold, M D, to Miss Linda Peyton Manly, both of Lexington, Va, September 7

Murdoch Bannister, M D, to Miss Keola Winona Williams, both of Ottumwa, Iowa, September 7

Garland Lightfoot Morris, M D to Miss Marie Louise Rice at Manchester, Va, September 7

James Clagett Robertson M D, to Miss Katherine I Groppel, both of Baltimore, September 14

Joseph L Abeln, M D, New Vienna, Iowa, to Miss Anna Luthmers of Dubuque, Iowa, September 6

Howard B Hamilton, M D, Ainsworth Iowa, to Miss Olive McClenahan of Monmouth, Ill, September 21

Martin L Brookshier, M D, Grymont, Ill, to Miss Josephine Beier of Weldon, Ill, September 7

Horace Wardner Eggleston, M D, to Miss Mable May Dunn, both of Binghamton, N Y, September 8

James McCann Stoddard, M D, Kennard, Ind, to Miss Ruby Eunice Palmer of Anderson, Ind, September 7

A Bernard Kuhl, M D, Walnut, Iowa, to Miss Elizabeth Munchrath of Davenport, Iowa, September 12

Samuel W Huston, M D, Perry, Iowa, to Miss Elizabeth J Owen of Columbus Junction, Iowa, September 13

William Dunn Powell, M D, Harrodsburg, Ky, to Miss Jane Cecilia Wise, at Leesburg, Va, September 3

Raymond V Glann, M D, of Apalachin, N Y, to Miss Amelia Mewshaw, at Glen Burnie, Md, September 4

David Este Weatherhead, M D Cincinnati, to Miss Clara Virginia Yates of Covington, Ky, at Chicago, September 8

Justin Frank Grant, M D, Morgantown W Va, to Miss Emily Jenks Bray of Boston, at Wilton, N H, September 7

George Ketcham Hagaman, M D, North St Paul, Minn, to Miss Mary Wilson Fagundus of Minneapolis, September 14

William H Hudson, M D, Atchison, Kan, to Miss Esther L Shreve of Chatham, Ont, at Kansas City, Kan, September 5

William Bay Stoker, M D, Harvard, Iowa, to Miss Malisse Helen Shadley of Belknap, Iowa, at Shenandoah, Iowa, September 2

Deaths.

Alexander Trent Clark, M.D Medical College of Virginia, Richmond, 1869, for many years chairman of the Halifax County Board of Health, and once a member of the State Board of Medical Examiners, died at his home in South Boston, Va, September 10, after an illness of several months, aged 62

William L Buechner, M D University of Giessen, Germany, 1853, one of the oldest practitioners of Youngstown, Ohio, and a founder of the City Hospital, was drowned, September 11, in a runaway accident near Youngstown, in which his horse plunged over an embankment and into a ravine, aged 73

Charles M Baker, M D Transylvania University Medical Department, Lexington, Ky, 1843, for many years a practitioner, and twice mayor of Henry, Ill, died at the Illinois Western Hospital for the Insane, Watertown, of which he had been an inmate for several years, September 3, aged 82

Martin S Kittinger, M D College of Physicians and Surgeons in the City of New York, 1853, surgeon with the Army of the Potomac during the Civil War, some time president of the Niagara County Medical Society, died at his home in Lockport, N Y, September 11, after a long illness, aged 77

Edward Payson Buffett, M D College of Physicians and Surgeons in the City of New York, 1857, for many years visiting surgeon at Christ's Hospital and the City Hospital, Jersey City, N J, died at his home in that city, September 9, from heart disease, after an illness of seven months, aged 70

John Cascaden, M D College of Physicians and Surgeons of Ontario, Toronto, 1866, at one time representative for West Elgin in the Ontario Legislature, died at his home in Dutton Ont, August 31, after an illness of three months, aged 64

James McCortney, M D Cleveland Medical College, 1853, one of the oldest physicians of Davenport, Iowa, surgeon in the Army during the Civil War, died at the home of his daughter in Chicago, September 8, from cystitis, aged 79

Felix E Schilling, M D Tulane University, New Orleans, 1903, of Collins, Miss, died at the South Mississippi Infirmary, Hattiesburg, September 12, from typhoid fever, after an illness of four weeks, aged 31

George M Kellogg, M D Medical College of Ohio, Cincinnati, 1852, formerly of Carthage, Ill, and a lecturer for several years in Keokuk Medical College, died at his home in Pasadena, Cal August 18, aged 73

A W Butler, M D University of Tennessee, Nashville, 1903 formerly interne at the Nashville City Hospital, died suddenly from nervous collapse, September 6, at his home in Nashville aged 24

Charles Hinkle, M D University of Louisville, 1861, surgeon in the Confederate service during the Civil War, died at his home in Hinkleville, Ky, September 13, after a long illness, aged 66

Harvey C Chappelear, M D Cincinnati College of Medicine and Surgery, 1871, died at his home in Mount Sterling, Ohio, September 14, after a long invalidism, from asthma

James R Kelch M D Starling Medical College, Columbus Ohio, 1864, assistant surgeon of the 155th Ohio Volunteer Infantry in the Civil War, died suddenly at his home in Tarlton Ohio, September 4, from heart disease, aged 70

Richard J Ough, M D University of the Queen's College, Coburg, Ont, 1869, supreme physician of the United Order of Foresters, died at his home in Chicago, September 11, aged 65

Emery F Redfern, M D Ohio, of South Perry, assistant surgeon in the 90th Ohio Volunteer Infantry in the Civil War, died recently, and was buried at South Perry, September 4

William M Gough, M D University of Louisville, 1848, surgeon in the Confederate service during the Civil War, died at his home in Los Angeles, Cal, September 7, aged 79

Christine Anderson, M D University of Michigan, Department of Medicine and Surgery, Ann Arbor, 1888, died at her home in Detroit, Mich, August 29, aged 40

Charles Walton Chaffee, M D College of Physicians and Surgeons of Toronto, 1883, died at his home in Toronto, Ont, May 26, from pneumonia, after a short illness

H H L Yeargan, M D Transylvania University Medical Department, Lexington, Ky, 1846, of Barefield, Tenn, died at his home in that place, September 5, aged 84

Alfred L Keene, M D Jefferson Medical College, Philadelphia, 1888, died at his home in Lancaster Pa., September 6 from heart disease, aged 43

P W Crum, M D, died at Borgess Hospital, Kalamazoo Mich, six months after a fall in which he fractured his hip September 2, aged 91

J Maude George, M D Woman's Medical College, Philadelphia, a medical missionary in China, died at her station in Macao, September 4

S Sylvester, M D University of the Victoria College Coburg, Ont, 1878, died suddenly at his home in Montreal, April 2, aged 46

Isaac Pankake, M D Medical College of Ohio, 1886, a member of the American Medical Association, of Frankfort, Ohio, died recently

Robert S Cheffey, M D College of Physicians and Surgeons of Ontario, Toronto, 1871, died at Toronto, September 11 aged 77

George L Smith, M D Jefferson Medical College, Philadelphia, 1850, died recently at his home in Groveport Ohio aged 79

Paul E Malmstrom, M D University of Lund, Sweden, 1890, died at his home in Kenosha, Wis, September 13, from heart disease

James K. Griffin, M.D Columbus (Ohio) Medical College, 1878, died suddenly at his home in Fitzgerald, Ga, September 7

Frank M Reasner, M.D Cleveland Medical College, 1865, died at his home in Los Angeles, Cal, September 11, aged about 70

Francis X. Spranger, M D Ohio, 1864, died suddenly at his home in San Jose, Cal, from apoplexy, September 3, aged 61

Thomas E Morris, M D McGill University, Montreal, 1899, died at his home in St John, N B, September 8, aged 30

Willis Duff Green, M D Medical College of Ohio, Cincinnati, 1844, died recently at his home in Mount Vernon, Ill

Albert M Loop, M.D, a member of the Medical Society of the State of Pennsylvania, died recently at Nelson, Pa

John T Smith, M D, died at his home in Cedar Rapids, Iowa September 2, after an invalidism of ten years

W E McBryde, M D, died at his home in Colmesneil, Texas, September 5, from congestion of the brain

William H Colvin, M.D Illinois, 1896 died at his home in Chicago, July 6, from pneumonia, aged 34

John H Stork, M.D Kentucky School of Medicine, 1888, died at his home in Stendal, Ind, September 6

Albert D Moxley, M D New York, 1877 died suddenly at his home in Jefferson, N Y, August 1

A. S Hayhurst, M D Indiana, 1887, died recently at his home in Evansville, Ind after a long illness

Thomas S Lackey, M D, 1849 died at his home in Mayfield Ky, September 12 aged 82

James A. Taylor, M D, died at his home in Wayne W Va September 6

Book Notices.

ELEMENTS OF GENERAL RADIOTHERAPY FOR PRACTITIONERS By Dr Leopold Freund Vienna Translated by G H Lancashire M D Brux. M R C S Eng L R C P Lond Assistant Physician to the Manchester and Salford Hospital for Skin Diseases With 107 Illustrations in the Text and One Frontispiece Cloth Pp 538 0 Price $5 00 New York Rebman Co 1904

RADIOTHERAPY PHOTOTHERAPY AND HIGH FREQUENCY CURRENTS The Medical and Surgical Applications of Radiology in Diagnosis and Treatment By Charles Warren Allen M.D Professor of Dermatology in the New York Post Graduate Medical School With 131 Engravings and 27 Plates Cloth. Pp 618 Price $4 50 net Philadelphia and New York Lea Brothers & Co

The rapidly growing literature on the medical uses of the various forms of radiant force, some of which we have but recently become acquainted with, receives here important additions Freund's work must be regarded as authoritative and fundamental, especially in so far as concerns the essential scientific principles of radiology The introductory chapters on physics are more exhaustive than in the other books on radiotherapy The technic of the practical application of these forces is also comprehensively described. A fully illustrated supplement contains adequate descriptions of the various instruments necessary for using high frequency currents *x* rays, heat and light rays The index is full and a complete list of the authors quoted, and the page where each may be found, together with the corresponding references, is given The indications for and results to be expected from the various radiotherapeutic measures are discussed on the basis of the existing literature, but we miss any statements concerning the diagnostic value of *x* rays We believe we may safely recommend this book to any one who desires to know the fundamental physical laws underlying radiotherapy, as well as its practical application It should be remembered that Freund is the man to whom we owe more than to any other the introduction of the Roentgen ray in therapy The work gives every impression of having a commensurate basis of personal theoretical and practical work on the part of the author

Dr Allen's book deals with the *x* ray light and high frequency currents Here the therapeutic and diagnostic aspects are given predominance, the nature of and laws governing the forces employed, receiving comparatively little attention It has seemed to the reviewer that there is an unnecessary diffuseness in some of the parts dealing with the therapeutic results of the *x* ray Surely much of the information here given in regard to the individual cases cited might well have been condensed into smaller space Both the works are adequately illustrated, Freund's especially from the side of physics and instrumentation, Allen's from the clinical The suggestion may be allowed that the field for the works of the kind represented by these two books is now well covered by these and other recent publications, it would, therefore, be better if as much energy and attention as possible were given to investigation of the many and important problems of theoretical and fundamental nature that are arising as a result of the introduction of the physical forces considered into medicine

A REFERENCE HANDBOOK OF THE MEDICAL SCIENCES, Embracing the Entire Range of Scientific and Practical Medicine and Allied Science By Various Writers A New Edition Completely Revised and Rewritten Edited by Albert H Buck M D New York City Volume VIII Illustrated by Chromolithographs and 435 Half tone and Wood Engravings Cloth Pp 784 Price $7 00 per volume New York Wm Wood & Co 1904

This volume completes this issue of the Reference Handbooks Included in this volume is an appendix which contains articles that from one cause or another were omitted from their regular position in the alphabetical order A most complete index occupying nearly two hundred pages, three columns to a page, closes the work This index will be found of great value, as it makes reference to any particular subject easy In the ordinary works arranged alphabetically as is this one, it is not common to go to the expense and trouble of getting out a detailed index as has been done here but, if not necessary, it is certainly very convenient

In our notices of the volumes as they came out, we have repeatedly spoken of the excellent manner in which the subjects were covered We have also called attention to the fact that while the handbook is published as a revised edition of a work which came out some twenty years ago, it is in reality a new book A few articles appear unaltered, a few others are modified but slightly from those appearing in the former edition, but the great bulk have been entirely rewritten, and many subjects appear that were not treated in the former edition The work is a complete encyclopedia of modern medicine, for so far as we are able to discover, nothing that belongs to such a work is omitted As a rule, the topics are considered in an exhaustive manner, and if published in individual books not a few of the articles would be accepted as complete monographs on the subjects treated The editor is to be congratulated on the good judgment displayed in allotting the amount of space to be given to a given subject, not an easy matter when the whole field of medicine had to be covered He is to be especially congratulated on his selection of the writers for the different subjects In nearly every instance the one selected is an authority on the subject on which he writes, thus guaranteeing reliability The publishers are to be congratulated on their liberality in illustrating the work and on presenting it in such a satisfactory manner, from a mechanical and typographical point of view This Reference Handbook is a library of itself, at least, it makes a good foundation for a complete library

ADENOIDS By Wyatt Wingrave M D Physician and Pathologist, Central London Throat and Ear Hospital Cloth Pp 128 Price $1 00 net Chicago W T Keener & Co 1904

In this little book of 194 pages are discussed clearly the various phases of nasopharyngeal adenoids, a subject in which the medical profession has taken an increasing interest, since the attention was definitely directed thereto by Meyer in 1868 Adenoids are described thoroughly from the anatomic etiologic and clinical points of view The operative treatment is given with adequate detail and a special chapter by Holten George deals with the subject of anesthetics. We can recommend the book to the general practitioner as a trustworthy guide to a thorough understanding of the subject with which it deals

Miscellany.

A Charity Patient —A French exchange relates as an anecdote that a woman was given $600 by her husband to pay the expenses of an operation which her physician had declared necessary She disguised herself as a poor woman and applied to the free public hospital, giving a false address, after having hired the persons at the address given to testify in her favor if questions were asked She then bought a jewel with the $600 which should have paid for her operation

Growth of Bacteria in Salt Solutions —F Lewandowsky of Strasburg tested a micrococcus and a mesentericus from a vegetable and reports that a 25 per cent solution of table salt inhibited the growth of the bacteria On the other hand, they continued to grow apparently unaffected in saturated solutions of potassium nitrite In a communication to the *Archiv f Hygiene,* xlix, No 1, 1904, he ascribes this difference in the action of the solutions to the comparative insolubility of the nitrate and the difference in the molecular concentration and of the specific ions in the two solutions

Intoxication from Unripe Tomatoes —A French physician reports in the *Lyon Med*, August 21, some cases of illness traced to the eating of tomatoes not perfectly ripe The discovery of fragments of the tomatoes was the only hint as to the cause of the trouble in the first case The dilatation of the pupils in all the sick members of the family was a noticeable symptom As the tomato belongs to the same family as the potato, the intoxication may have been like the solanum poisoning sometimes observed after ingestion of unripe or spoiled potatoes Recovery was rapid after emptying the stomach

Automatic Compressive Dressings— The *Gazette Med de Paris* for August 27 contains an illustrated article by P Mantel of Saint Omer describing his method of applying a dressing to obtain automatic compression of the parts without straps of any kind It is shown applied to the head and to the stump after an amputation The gauze or cotton are applied as usual Then four or more rather wide strips of gauze are placed flat on the vertex or the bottom of the stump, crossing them at right angles to each other An assistant pulls on the ends of these strips, and another longer strip of gauze is wound around over them from the periphery toward the center When this is all in place the loose ends of the crossed strips are brought down over the wound bandage and fastened together flat below A dressing thus applied to the head does not require any further support, but exerts great pressure on the top of the skull, without the necessity for any straps under the chin or elsewhere

The Public Service.

Army Changes

Memorandum of changes of station and duties of medical officers U S Army week ending Sept 17 1904

Field Peter C, asst surgeon granted thirty days leave of absence

Bratton Thos. S asst surgeon relieved from duty at Fort Sam Houston Texas and ordered to Chicago for duty as attending surgeon and examiner of recruits

Purviance Wm E surgeon relieved from duty as attending surgeon and examiner of recruits Chicago, and ordered to Manila P I for duty

The following named asst surgeons are relieved from duty at posts designated after their names and will report on Oct 1 1904 to Col Charles L Heizmann asst surgeon general president of the faculty Army Medical School Army Medical Museum Building Washington D C, for a course of instruction at school Davis Wm R. San Francisco Owen Leartus J Fort Myer, Va , Zinke Stanley G, Fort Riley Kan Cutler, Robert M Fort Jay, N Y , Weed Frank W Fort McHenry Md Wickline Wm A Fort Ethan Allen, Vt Brown Henry L Columbus Barracks, Ohio Bally, Howard H Plattsburg Barracks N Y Humphreys Harry G Fort Totten N Y Freeman Paul L Fort Slocum N Y

Roberts Wm M, asst. surgeon granted twenty one days' leave of absence

Tefft Wm H, asst surgeon, left Fort Snelling, Minn, for duty at Camp Lakeview Minn

Barney Chas N asst surgeon left from duty at Gainesville, Va on twenty days' leave of absence

Thornburgh R M asst surgeon reports at U S Army General Hospital Washington Barracks D C for temporary duty from Manassas Va

Rockhill, E P, asst surgeon, order for temporary duty at Fort Miley, Cal, revoked

Chase A M, contract surgeon reports his return to Fort Reno, Okla, from three months leave of absence

Burr, R T, contract surgeon, granted leave of absence for three months

Bailey, Edward B, contract surgeon, granted leave of absence for one month

Griswold, W Church, contract surgeon, granted leave of absence for one month

Jones, John F, contract surgeon, granted fifteen days' leave of absence

Marshall, John S, supervising and examining contract dental surgeon, leave of absence extended ten days

Treuholtz C A, contract surgeon, granted leave of absence for two months

Shellenberger James E contract surgeon, granted leave of absence for one month and fifteen days

Navy Changes.

Changes in the medical corps U S Navy for the week ending Sept 17, 1904

Green, E H medical inspector, ordered to the Navy Yard, New York, October 1

Bertolette D N, medical inspector, detached from duty as a member of the naval retiring board and of the naval and medical examining boards, Washington, D C, and ordered to resume other duties

Price A F, medical director detached from the Navy Yard New York, October 1, and ordered to duty as a member of the Naval retiring board, Washington D C

Bieck, F W, pharmacist ordered to the Naval Hospital New York

Marine-Hospital Service

List of changes of station and duties of commissioned and non commissioned officers of the Public Health and Marine-Hospital Service for the seven days ended Sept 14 1904

Purviance George, asst surgeon general granted extension of leave of absence for one month from Sept. 1, 1904, on account of sickness

Vaughan G T asst surgeon general detailed to represent the service at meeting of the Association of Military Surgeons to be held at St Louis, Oct 10 15 1904

Peckham C T surgeon, granted leave of absence for one month from October 8

Wertenbaker C P, surgeon detailed to represent the service at the meeting of the Association of Military Surgeons, to be held at St Louis Mo Oct 10-15, 1904

Wickes, H W P A surgeon, directed to proceed to Wilmington Del for special temporary duty

Parker H B P A surgeon granted leave of absence for one month from October 1

Robertson H McG, asst surgeon temporarily relieved from duty at Stapleton N Y and directed to proceed to Washington, D C and report at the Bureau for temporary duty

Rucker W C asst. surgeon granted leave of absence for four three days from September 8

Goldsborough B W, A A surgeon, granted leave of absence for three days from September 8

Horsey, J L, A A surgeon granted leave of absence for fourteen days from September 10

Mason W C A A surgeon granted leave of absence for five days from September 19

Stevenson J W A A surgeon, granted leave of absence for seven days from September 3 1904 on account of sickness

Tuttle Jay A A surgeon, granted leave of absence for seven days from September 12

Goodman F S pharmacist, granted leave of absence for three days from Sept 3 1904 under Paragraph 210 of the Regulations

Scott, E B pharmacist granted leave of absence for twenty five days from September 19

Slough Chas pharmacist, Department letter of Aug 3 1904 granting leave of absence for thirty days from August 10 amended to read nine days from August 17

RESIGNATION

Kolb W W pharmacist resigned to take effect Sept 1 1904

Health Reports

The following cases of smallpox yellow fever cholera and plague have been reported to the Surgeon General Public Health and Marine Hospital Service during the week ended Sept 16, 1904

SMALLPOX—UNITED STATES

Florida At large Sept. 3 10 19 cases
Illinois Chicago Sept 3 10 1 case
Indiana Kokomo Sept 3 10 1 case
Louisiana New Orleans, Sept 3 10, 1 case
Massachusetts Sept 3 10 Lowell 1 case North Adams, 2 cases, 1 death

Medical Society of Virginia, Richmond, October 18-21

AMERICAN ASSOCIATION OF OBSTETRICIANS AND GYNECOLOGISTS

Seventeenth Annual Meeting, held at St Louis,

Sept 13 16, 1904

Under the presidency of Dr Walter B Dorsett, St Louis

Addresses of welcome were delivered on behalf of the St Louis Obstetrical and Gynecological Society by Dr Louis E Newman, and on behalf of the city and the *exposition* by David R. Francis, president of the Louisiana Purchase Exposition The responses to these addresses of welcome were made by Dr L. H. Dunning, Indianapolis, and Dr Herman E Hayd, Buffalo, N Y The meeting was very well attended. The papers were of a high scientific character and the discussions on them full and spirited. The association held only one session a day, in the morning, thus giving the members and their guests an opportunity to visit the exposition in the afternoons and evenings

Officers for the Ensuing Year

The following officers were elected for the ensuing year President, Dr H W Longyear, Detroit, vice presidents, Dr D Tod Gilliam, Columbus, Ohio, and Dr John Young Brown, St Louis, secretary, Dr William Warren Potter, Buffalo, N Y (re elected) treasurer, Dr X O Werder Pittsburg (re elected)

The association will meet in New York City in 1905

(*To be continued*)

AMERICAN ROENTGEN RAY SOCIETY

Fifth Annual Meeting, held in the Louisiana Building, St Louis, Sept 9 13, 1904

The President Dr James B Bullitt, in the Chair

Election of New Officers

The following officers were elected President, Charles Lester Leonard Philadelphia vice presidents Weston A Price Cleveland, Henry Hulst, Grand Rapids, Mich , Gordon G Burdick, Chicago, secretary, Russell H Boggs, Pittsburg, treasurer, Leavitt E Custer, Dayton, O , member of the executive committee, George C Johnston, Pittsburg The following committees, to be appointed later by the president, were provided for Committee on Histologic, Physiologic and Bacteriologic Influence of the *X* Ray, Committee on Technic of Radiotherapy, Committee on Technic of Radiography The constitution was amended to provide for a Board of Censors, said board to consist of the three last presidents, Drs George P Girdwood, Montreal, Canada, A W Goodspeed, Philadelphia, and James B Bullitt, Louisville, Ky The place of next meeting will be either Detroit or Cleveland, to be determined later by the *Executive Committee*

The election of officers was followed by the president's address

Comparison of X-Ray and Surgical Treatment for Tuberculosis

Dr Bullitt put two propositions 1 Is the present surgical treatment of the forms of tuberculosis imminently and entirely successful and satisfactory? 2 What is the probability that the Röntgen ray method of treatment is capable of rendering the treatment of such diseases more rapid and successful? He made inquiry of various operators as to results obtained in the treatment of tuberculosis of long and flat bones, joint structures, tendon sheaths, peritoneum, testicle and lymph glands No mention was made of the length of time that elapsed between the beginning and the end of the treatment, number of exposures made, conditions of the exposures and technic, nor is it stated that some cases get worse rather than better under the *x* ray treatment A possible mortality from *x* ray treatment is out of the question The reports indicate that in some cases at least the tuberculous process can be cut short by exposure to the *x* ray, that a cure can be affected in much shorter time and in diseases of the bones and joints, with much better functional results than is to be expected from the usual surgical methods The Röntgen ray, says the author, is not to be regarded as a perfect method of treatment in tuberculous disease, but may be considered to be of great value The following summary is presented Long and flat bones—Cases treated, 71, cured, 33 per cent , improved, 35 per cent , not benefited, 29 per cent Joints—Cases treated, 141, cured, 38 per cent , improved 37 per cent , not benefited, 25 per cent Tendon sheaths—Cases treated, 27, cured, 70 per cent , improved, 22 per cent., not benefited, 0 7 per cent Peritoneum —Cases treated 32, cured, 40 per cent , improved, 25 per cent not benefited, 35 per cent Testicle—Cases treated, 21, cured 33 per cent , improved, 48 per cent , not benefited, 19 per cent Lymph glands—Cases treated, 226, cured, 35 per cent , improved, 40 per cent , not benefited, 25 per cent Lupus—Cases treated, 616, cured, 68 per cent , improved, 24 per cent not benefited, 8 per cent.

This was *followed* by a *symposium on x ray* in *tuberculosis*

The X-Ray in Tuberculosis and Malignant Diseases.

Dr J D Gibson Denver Colo said that for the treatment of deep seated growths a light made by a powerful machine and capable of great penetration is required.

The X Ray in the Treatment of Pulmonary Tuberculosis

Dr Emil Grubbe, Chicago, has found that the *x ray is particularly* valuable in the acute cases, in which prominent symptoms are loss of appetite, weight and strength, slight rise of temperature, cough and expectoration, but no hemorrhage, and in chronic cases, and that the sooner the treatment is begun the better

The Roentgen Ray in the Treatment of Tuberculosis

Dr J Rudis Jicinsky, Cedar Rapids Iowa, insists *on* an early diagnosis and plenty of fresh air and sunshine as adjuvants of the *x* ray treatment of tuberculosis He uses a tube which has a prolongation from the middle of the *x* ray field proper made of lead glass except the end where the rays emanate, which must be flint glass enabling the rays to emerge at this point, which is laid right against the lesion

The remainder of the tube is enclosed in a special shield This does not endanger the patient, and only the diseased area is rayed Since December, 1902, he has treated 20 cases, 5 were of the hemorrhagic variety and improved in ten weeks and are still doing well, 10 cases were of the fibroid variety, and 3 of them died after six weeks, 2 as the result of intestinal complications and 1 from tubercular meningitis, the remaining 4 are slowly yielding to treatment, 2 cases of mixed infection are gaining steadily in weight Of 6 cases of tuberculosis of the peritoneum, 1 died, and the other 5 are well and have not had a recurrence Of 19 cases of lupus, 16 are apparently cured, and in 3 the treatment was negative In glandular tuberculosis, 8 cases are cured, 6 are benefited, 19 are failures and 4 cases are still under treatment and doing well In tubercular laryngitis he uses the ray as a prophylactic measure only, and 2 cases out of the 8 seemed benefited Eight cases of joint tuberculosis were cured in six weeks, 4 chronic cases were benefited in four months, 2 cases of tuberculosis of the testicle were cured and have not recurred in three months

The X-Ray in Tubercular Adenitis

Dr Max Cushman Rice, Chicago, reported a case of tubercular adenitis in a girl aged 18, who had been operated on five times, the disease recurring again X ray treatments were then given three times a week, ten minute exposures, with a medium vacuum tube, tube distance three inches After the third treatment the glands began to diminish in size and at the end of two months the largest gland was about the size of a bean There was a corresponding increase in weight and improvement in general health The second case, a woman, aged 32, disease of five years standing, was treated with the high frequency current by means of the Tesla coil and static machine, with only slight improvement The *x* ray was substituted, and after five months the glands could scarcely be felt

DISCUSSION

Dr G G Burdick, Chicago, emphasized the importance of not restricting the treatment of tuberculosis to the *x* ray, but to look on the *x* ray as a most valuable agent when used with other remedial agents

Dr George E Pfahler, Philadelphia, suggested that a great many cases of tuberculosis get well without ever seeing a doctor and without ever knowing that they had tuberculosis, a fact of which we must not lose sight when we draw conclusions as to the efficacy of the *x* rays in the treatment of tuberculosis He has had very gratifying results from the use of the *x* ray in the treatment of all forms of tuberculosis In treating tubercular glands, especially those of the neck we should also expose the lung, because most of these cases have some involvement of this organ He never protects anything except the hair and face of the patient

Dr C L Leonard, Philadelphia said that in using the *x* ray we must be governed by a dosage which is known and can be measured and that on this will depend the results that are obtained Its action in tuberculosis is that of an alterative and a stimulant, but we must not depend on that agent alone

Dr E G Williams, Richmond, Va , emphasized the fact that all his patients had improved in general health under the *x* ray treatment One case gained 70 pounds in nine months The *x* ray stimulates metabolism more than any other agent

Dr Henry Hulst, Grand Rapids, Mich , has had good results in the treatment of tuberculosis of glands, joints and peritoneum He has never used it in pulmonary tuberculosis because a perusal of the literature has convinced him that when the *x* ray is used critically no good results are obtained

Dr S Tousey, New York City, reported a wonderful improvement in a case of tuberculosis of the larynx, using the method advocated by Dr Rudis Jicinsky In four months the ulcerations had healed almost entirely He also reported considerable improvement in a case of tuberculosis of the prostate gland which was treated by raying the abdomen and by letting the rays shine into the rectum through a specially constructed tube

Dr C E Skinner, New Haven, Conn , used the *x* ray in three cases of advanced pulmonary tuberculosis, but was unable to perceive any influence whatever in any of the cases

Dr. George C Johnston, Pittsburg, reported similar results His experience leads him to prefer climatic to *x* ray treatment The treatment of tuberculosis under ordinary climatic conditions by means of the *x* ray alone is a failure

This was followed by a symposium on the treatment of malignant diseases

The Treatment of Epithelioma

Dr George C Johnston, Pittsburg, divides his cases, first those in which, owing to location, extent, metastasis, condition of the patient, and various other factors, a cure can not be expected, and, therefore, treatment is purely symptomatic, second, those cases in which the location and other condition are such as to permit of the expectation of a cure He gives daily treatments for the first ten days, unless an undesirable degree of reaction occurs, when the treatments are given at longer intervals After the first ten days treatments are given every third day until the desired results are obtained If the results do not appear, the dose may be increased cautiously, bearing in mind the cumulative tendency of the agent employed The degree of success obtained will be in direct proportion to the experience of the operator, the correctness of his technic, his familiarity with the apparatus used and his ability to distinguish an active from a worthless tube He reported 44 cases of epithelioma about the face The average duration of these cases is four years and eight months, 34 were primary and 10 recurrent cases The average number of treatments in each case was 22 Metastasis occurred in only 3 cases, 30 cases were cured, 8 were benefited 3 recurred, and 3 died

Radiotherapeutic Nihilism

Dr G G Burdick, Chicago, insists on the importance of having a reliable technic which can be followed by unskilled as well as by skilled operators He proposes the following In lupus and other forms of local tubercular involvement, the tube distance should be four inches and the penetration regulated to within half an inch in order to take advantage of the ray of low velocity, which resembles the cathode ray In carcinoma and epithelioma the tube distance should be ten inches and the penetration calculated to reach the center of the growth, producing irritation at least twice, and then increasing the degree of penetration to a high velocity, in order to get cellular degeneration Sarcoma requires a very high degree of penetration, depending on the density of the growth When it is desired to take advantage of the tonic effect of the ray a high tube should be used Where the lethal effect is desired a low tube should be used It must be remembered that the tonic action of the ray is due to its fluorescence, this being understood as a form of motion, and that the lethal effects are the result of chemical radiations All carcinomata which have not ulcerated should be rayed thoroughly before they are removed by operation

The X-Ray Treatment of Sarcoma

Dr Joseph F Smith, Chicago, reported 18 cases of deep seated sarcoma in various organs and tissues in which *x* ray proved a most severe disappointment

The Results of Treatment of Carcinoma

Dr J N Scott, Kansas City, Mo , said that one great advantage of the *x* ray is that it can be applied to large areas and to vital organs, if used with care One disadvantage is the long period of time over which the treatment must be extended All tumors operated on and found to be malignant should have a course of *x* ray treatment, and if at the end of from one to three months no recurrence has set in the patient may be considered as cured, but should be kept under observation

Carcinoma of the Breast

Dr Charles L Leonard, Philadelphia, said that the essential factor of any successful treatment of malignant disease is that it be radical and used early, its severity to be limited only by the patient's general vitality and of the normal tissues that surround the affected area Thorough surgical treatment, wherever consistent with the preservation of the function of life of the area involved should be advocated as the primary treatment. If any aid is to be expected from Röntgen ray treatment it must be commenced immediately after the surgical operation, before the patient is out of bed The healing of wounds and the closing of sinuses are hastened by Röntgen ray treatment. A careful study of the results obtained by this treatment in malignant disease of the breast shows that it has been most affected where it supplements rather than supplants operation In inoperable and hopeless cases it affords relief from intolerable symptoms, lengthens life and offers the patient the most The best results are obtained in scirrhus, in fact, the only favorable results of primary treatment have been obtained in these cases Metastasis can be influenced and held in check by the Röntgen ray treatment In all other cases surgical removal of the breast and the adjacent lymph glands is always indicated Technic and experience, as well as local and constitutional treatment, are essential to success in the treatment of malignant disease of the breast He reported 26 cases treated since 1900 Of this number, 12 are dead, 2 have not been heard from, and the remainder are living Two had preparatory treatment, and they have lived eighteen and sixteen months respectively One had a primary inoperable scirrhus, 4 had recurrences, in 3 the recurrence has disappeared entirely and has not recurred in twenty one, ten and four months respectively In 1, massive recurrence followed immediately after operation Of the cases receiving post-operative *x* ray treatment, 4 are living and are free from recurrence, nineteen, fourteen, twelve and seven months after operation Of the 12 patients who died, all except 3 were benefited when first seen Two of them had post operative treatment, but died eighteen months after the operation. He considers the results very encouraging and urges further study and observation in the treatment of malignant disease of the breast with the *x* ray

Variations of Radiotherapeutic Technic.

Dr. Russell H Boggs, Pittsburg, advocated the employment of more accurate methods and suggested that some perfect results that are reported in the treatment of tuberculosis or malignant disease may be due to the perfect technic employed by the operator or to a wrong diagnosis He insisted that the most important point is the tube distance, because the intensity of the light varies inversely as the square of the distance For skin lesions there is no occasion to place the tube more than from 4 to 6 inches from the skin, but that is not the case in the treatment of deep seated lesions Another important point is that the *x* ray should be of large volume when deep lesions are to be treated. A low vacuum tube at a distance of from 12 to 16 inches will penetrate the tissues effectively With reference to cancerous disease, he spoke of cases of small epitheliomata situated on the face, which can be cured in from 6 to 8 weeks, depending on the vitality of the patient. In cases in which the disease appears to be localized, the tumor should be removed at once and followed up by *x* ray treatment Cases having considerable glandular involvement should be treated for a time with the *x* ray, then operated on, and treated again with the *x* ray Usually, twenty treatments before and twenty after operation are all that are required. Those cases that are considered inoperable should be treated by the *x* ray because of its inhibitory action on the disease and for the comfort it affords the patient All cases should be given tonic treatment as well. Alcoholics, syphilitics and anemic patients in general do not as a rule, improve rapidly Such cases should receive individual specific medication in addition to the *x* ray treatment

Cases of malignant disease were reported by the following George C Johnston, C L Leonard, J F Smith J N Scott, G G Burdick, R. H Boggs, W W Johnson, M K Kassabian, C F Pfahler and E G Williams

The Compression Tube in Skiagraphy of Calculi.

Dr. Henry Hulst, Grand Rapids, reported the good results he has obtained from the use of his compression tube, a modification of the Albers Schoenberg *"compressions-blende,"* in skiagraphy of fat people

The Interpretation of Radiographs of the Chest

Dr P M Hickey, Detroit, Mich, said that in order to secure the best results perfect mastery of the tube and employment of stationary secondary current and the use of developers which will secure the greatest detail and contrast are necessary It is also necessary that the observer should be experienced in the reading of these negatives The exposure should be made as rapidly as possible with a view to securing the greatest amount of contrast To interpret these negatives we should know the position of the target of the tube with reference to the area exposed, and a suitable illumination of the negative by means of the illuminating box is essential Furthermore, careful distinction should be made between physiologic and pathologic conditions, such as a large or vigorously pulsating aorta and an aneurism of the aorta

The X-Ray in Injuries Near the Wrist.

Mr. M Wilbert, Philadelphia, called attention to the fact that fractures of the lower end of the radius are frequently complicated by other more or less extensive injuries, and that the other bones entering into the formation of the wrist joint are also subject to fracture Fractures at or near the wrist joint are extremely common and vary considerably, both in location and direction, and in the nature and extent of the injuries to other structures Of the 26,011 cases of fracture rayed by him 660 were at or near the wrist joint When skiagraphing a joint it is important to include as much of the surrounding tissues as possible so that any fractures near the joint may be detected In fracture of the wrist joint, fracture of the carpal bone is very common

The Value of Stereoscopic Skiagraphy

Dr M K. Kassabian, Philadelphia, discussed this subject and exhibited an apparatus which is used for stereoscopic examination.

Diagnosis of Brain Tumors and Softening

Dr George E Pfahler, Philadelphia, exhibited a series of skiagraphs made for the purpose of diagnosing and locating brain tumors and abscesses of the brain. He said that he would never take the responsibility of an operation on the brain purely on skiagraphic evidence On the other hand, all cases of brain lesion should be examined by the *x* ray in order to confirm or add to the clinical evidence

---

Therapeutics.

[Our readers are invited to send favorite prescriptions or outlines of treatment, such as have been tried and found useful, for publication in these columns. The writer's name must be attached, but it will be published or omitted as he may prefer It is the aim of this department to aid the general practitioner by giving practical prescriptions and, in brief, methods of treatment for the diseases seen especially in everyday practice Proper inquiries concerning general formulae and outlines of treatment are answered in these columns without allusion to inquirer]

Heart Disease

DIET

Schott, in the *Lancet*, discusses the diet in heart affections, and gives the following two rules 1 Patients must avoid everything which excites the action of the heart, and 2, they must shun everything which embarrasses the heart's action The substances which most readily cause excitation of the heart are coffee, strong tea, and alcoholic liquors These stimulants should be avoided, even in cases where there has been habitual use of them, except in cases where the withdrawal would result in collapse In these cases, which have been accustomed to the use of alcohol, it is best to give Rhine wine Moselle, or Bordeaux, which has been matured for from eight to ten years If it is found necessary to administer other than the light wines, Cognac or whiskey mixed with plain water may be given No aromatics should be given with the alcohol because of the danger of irritability of the stomach leading to anorexia and insomnia Water and milk are the beverages to be preferred Cocoa deprived of its fat is good, but chocolate does not usually agree If it is desired to give fats pure cream or cream mixed with milk may be given To avoid embarrassment of the heart too hearty eating of foods which produce flatulence must be interdicted They may prove harmful in three ways 1 The diaphragm is pressed up against the lungs so that respiration is impeded and dyspnea results 2 The diaphragm is pressed up against the heart, forcing it upward and outward so that its action is carried on with greatly increased effort 3 Intra-abdominal pressure is increased and the abdominal vessels are compressed Therefore, all effervescing beverages, carbonated waters, champagne, or beer usually disagree with patients suffering from heart disease

INTERVALS OF FEEDING

On account of the necessity of avoiding overloading of the stomach, it is best that these patients should eat at three hour intervals, and the last meal of the day should be taken from two to two and one half hours before bedtime, otherwise there is danger of disturbed sleep

KINDS OF FOOD

Soups should be taken sparingly, chiefly because their nutritional value is too low in proportion to the bulk A few tablespoonfuls only should be recommended New bread and freshly baked cakes must be avoided Toast and zwieback or crust of rolls may be allowed Of the vegetables, those difficult of digestion and producing flatulence must be avoided, as beans, peas, lentils, sauerkraut, red cabbage, leeks, onions, garlic and celery Potatoes, boiled or in form of purées, are to be preferred to the less digestible baked potatoes Turnips and carrots may be eaten when young Other fresh and easily digested vegetables can not be too highly recommended. Meats are allowable, but the following must be avoided Eels, fat goose breasts, goose liver pies, rich sauces, mayonnaise on salmon, lobsters, or crabs, highly smoked or salted fish, because of the thirst they produce, fat ham, or bacon, sausages, seasonings and spices, red and black pepper nutmeg, mace, cinnamon and vanilla

FRUITS

Easily digestible stewed fruits are allowed because of their favorable action on the intestinal peristalsis Raw fruits which have to be peeled are desirable Grape stones should be removed before grapes are eaten Raspberries, gooseberries, currants, billberries, cranberries, pineapples, walnuts and Brazil nuts are to be prohibited

HOT AND COLD DRINKS

Ice in any form, either as iced drinks, fruit ices, etc, is prone to cause gastrodynia, and may produce congestion of the liver This should be kept in mind when ice is prescribed for vomiting

GENERAL INSTRUCTIONS TO PATIENT

A mixed diet of both meats and vegetables is to be given Thorough mastication and ensalivation of all the food is as indispensable in affections of the heart as in diseases of the stomach Of the use of tobacco the author states 'I always recommend patients suffering from heart disease either to give up smoking altogether or else to indulge in it most sparingly, and in the latter case to use very dry tobacco and a long mouthpiece or a pipe A patient should always be informed that smoking is bad for his heart disease" Drinking at meal time should be restricted Gentle exercise in the open air for a short time after meals is to be recommended Each case should be studied and the treatment should be modified in correspondence with the symptoms

TREATMENT OF CASES WITH ADEQUATE COMPENSATION

Abram, in the *Lancet*, Aug 6, 1904, gives the following suggestions for the treatment of various conditions under the following subdivisions

When compensation is practically equal to the lesion, the author believes that the patient should be told of his trouble in order to obtain his intelligent co operation in conducting his mode of living He should be warned against excesses of all kinds, mental and physical Exercise in moderation may be permitted, but never in competition If cycling is indulged in care should be taken not to struggle against head winds or up hill Moderation in the use of alcohol and tobacco must be enjoined, in fact, abstinence is advised In this stage of a mitral stenosis if a hemoptysis occurs, the author uses a free saline purge with a dose of opium If the patient is a woman and the lesion aortic she should be barred from marriage Well compensated cases of mitral regurgitation often pass through pregnancy without trouble Cases of mitral stenosis should be carefully watched during pregnancy "Our advice should certainly be against marriage"

TREATMENT OF CASES WITH PAIN AND DYSPNEA ON EXERTION

In this subdivision are cases in which palpitation, precordial pain, and dyspnea are manifest on exertion, and in a more advanced degree, some passive congestion, with its results in the kidney and liver In aortic cases throbbing in the neck vessels, headache, and giddiness may be troublesome Absolutely the best treatment is rest in bed for a week, with limitation of fluid and regulation of the diet and moderate purgation In aortic cases bromid and iron give relief General tonics, iron and strychnin, and small doses (two to three minims) of the tincture of digitalis, where rest can not be taken, will aid materially If there are diseased arteries with high tension, a rigid milk diet and diuretics are indicated.

CASES WITH SIGNS AND SYMPTOMS OF FAILING HEART

Such cases have to sit upright Limitation of fluid is often serviceable The bowels may be gently acted on For insomnia and the maniacal states frequently seen in aortic disease, trional, sulphonal or paraldehyd are useful, but opium is "our sheet anchor" Of the use of digitalis in aortic cases the author says "When we find thickened arteries and possibly some increase of tension there is no doubt that the best line of treatment is to limit the fluid taken, open the bowels, and give renal diuretics If cardiac stimulants are used I prefer strophanthus When the pulse tension is low digitalis is demanded, and also in cases where the mitral valve has yielded Dyspnea is often relieved by the use of atropin and strychnin hypodermically The 'sinking' sensation may be alleviated by the administration of solid opium or 'neat' brandy"

Chronic Colitis.

Shoup, in *Amer Med*, gives the following suggestions for the treatment of this condition

1 He believes the cause to be due in a large measure to displacement of the abdominal organs and the consequent indigestion and its sequelæ therefore, he replaces the organs and holds them in place by a properly fitted corset It is the invention of a Paris physician, and has a long, straight front, coming well down over the hips, and as low as can be worn in front, and is held down to the hose by elastic fasteners It is made to give firm pressure around the hips, and should be put on while the patient is lying down, and laced from below It may be necessary to change the corset several times before it is suited to the individual case

2 Make a chemical examination of the stomach contents and select a diet to suit the needs of the individual case If hydrochloric acid is much diminished or absent, meats should be partially or wholly excluded in the beginning of the treatment In cases with extreme constipation and passage of mucus, the diet of von Noorden, leaving a large residue and consisting of graham, whole wheat, or corn breads, spinach, cabbage, lettuce, asparagus, cresses, etc, has given the best results The explanation offered is that a bulky meal passes more quickly out of the stomach and through the intestine and overcomes the constipation, which is a most troublesome symptom If diarrhea is present the diet should be milk, broths, gelatin, eggs, custards, and peptones If the patient is nervous, a rest of two hours after the main meal should be insisted on When patients are thin, fats are indicated, and of these butter, cream and olive oil are to be preferred The olive oil may be given before breakfast, and in some cases before other meals as well

3 Assist digestion by the administration of hydrochloric acid and some one of the digestive ferments, such as pancreatin, papain, and diastase and bitter tonics, such as gentian or nux vomica. Allay fermentation by the use of intestinal antiseptics, such as salol, resorcin, and creasote.

4 Keep the bowels open by the use of oils by mouth, when the diet and olive oil fail castor oil is the best remedy to use Salines are not effective. Massage of the colon is also useful

5 Local treatment should consist of high enemas of alkaline solutions, followed by an astringent, such as krameria or silver nitrate. Large enemas of olive oil should be given while the patient is in the recumbent position, and allowed to flow by gravitation high up into the colon, they are soothing, healing and lessen constipation.

6 See that the patient gets sufficient rest in the recumbent position, and when practical, a change of air, at the mountains or seashore

7 Treat the attack of pain which precedes the passage of mucus by a hypodermic of morphin and atropin, and promote evacuation of the bowels by the method mentioned above

Urticaria.

Van Harlingen recommends the following

℞	Magnesii sulphatis	℥i	30	
	Ferri sulphatis	gr iv		25
	Sodii chloridi	ʒss	2	
	Acidi sulphurici dil.	ʒii	8	
	Infus quassiæ q s ad	℥iv	120	

M. Sig Tablespoonful in glassful of water before breakfast

Duhring recommends the following for local use

℞	Acidi carbolici	ʒiss	6
	Glycerini	ʒii	8
	Spiritus vini rect		
	Aquæ amygdalæ amaræ, āā	℥viii	240

M. Sig Apply locally two or three times daily to relieve itching and burning

The following is recommended for use in neurotic subjects

℞	Liquoris potass arsenitis	m xxiv	1	60
	Potassii bromidi			
	Syrupi aurantii corti, āā	ʒiv	16	
	Aquæ dest. q s ad	℥iii	90	

M Sig Teaspoonful three times a day

Medicolegal.

Insane Delusion Defined—The Court of Chancery of New Jersey holds, in the case of Davenport vs Davenport, that an insane delusion is a fixed belief based on supposed facts which exist only in the diseased imagination of the deluded person, persisted in against indisputable evidence of its falsity A mistaken conclusion, arrived at on consideration of existing facts, is not an insane delusion, although the facts may not justify the conclusion.

Indecent Physical Examinations.—The Supreme Court of Iowa says that the case of Garvik vs the B, C R. & N Railway Company was tried as if the charge was rape, by an employe of the company, and that counsel for the company asked that the jury go into a room and examine the man, who consented that it be done. The Supreme Court does not think that the examination by the jury should have been permitted It says that there was no showing that the private parts were in the same condition as they were when the assault was said to have been committed Moreover, the ultimate question was not the exact condition of this member, but whether or not the owner was physically incapacitated from having sexual intercourse The court doubts if this could be determined by a non expert from a mere examination of the penis Again, it says, the examination was indecent and should not have been tolerated Wounds resulting from injuries may undoubtedly be exhibited in open court to the jury, but even here no indecent exposures should be made. Furthermore, the evidence was not demonstrative in character The court adds that it has found no authority which justified the ruling made by the trial court, and that it doubts if there is any to be found in the books Be it remembered, it continues, that the plaintiff was entitled to be present during the entire trial with her counsel, and that there were others aside from the witness (employe) who were entitled to be present at the examination of his private parts "Let it be said, once for all, that we can not lend our support to such a shocking and indecent performance as was permitted in this case"

What Are Included in Privileged Communications.—Section 4,608 of the Iowa Code contains the provision "No practicing physician who obtains such information by reason of his employment shall be allowed, in giving testimony, to disclose any confidential communication properly entrusted to him in his professional capacity, and necessary and proper to enable him to discharge the functions of his office according to the usual course of practice." The Supreme Court of Iowa says, in the personal injury case of Battis vs C R. I & P Railway Company, that all will agree that the manifest purpose of this statute is to make it possible for every person to fully and freely consult with a physician, or submit himself to the examination of such physician, without anticipation or fear that the confidence reposed may be broken in on by a subsequent examination of the physician as a witness in some form of legal proceeding This being true, the statute should have a liberal construction by the courts Accordingly this court has held that the expression "confidential communications," as used in the statute, is not to be restricted to the mere verbal statements made by the patient, but must be construed to include all knowledge or information acquired by the physician through his own observation or examination In the case at bar the interrogatories propounded to the physician were intended to elicit from him certain facts respecting the condition of the plaintiff, and it was manifest that whatever knowledge the witness possessed was acquired from the statements made to him by the plaintiff, and from his own examination and observation Clearly in such a case the statute applies, and the privilege may be insisted on Nor is the privilege taken away, as contended for, by the fact that while on the witness stand, and elsewhere, the plaintiff had stated that he was unconscious when taken to, and while he remained in, the office of the physician, and that the testimony sought to be elicited had relation solely to the condition of the plaintiff as to consciousness, the purpose thereof being the impeachment of the plaintiff as a witness It may be true, possibly, that the knowledge acquired by the physician was not, in point of fact, and strictly speaking, necessary and proper to enable him to perform the functions of his office But of this the court is not in position to judge, nor is it called on to determine what the fact might be when reduced to a last analysis It was the condition of the plaintiff that was the subject of the inquiry, and it was the professional judgment of the physician that was called for The privilege can not be subject to measurement by metes and bounds, and the court may well assume that all that was told to the physician, and all that was developed by his examination or came under his observation, was necessary and proper for his understanding of the condition of his patient The relation of physician and patient being established, if by any fair intendment communications made have relation to the physical or mental condition of the patient, the court is bound to hold them privileged With reference to the local surgeon of the company, called by the station agent to see the plaintiff, the court says that it may be conceded that the sole purpose of the agent in calling this physician was that the latter might ascertain the condition of the plaintiff, and thus be prepared to advise the company should occasion therefor arise, or be a witness on its behalf if necessary Certainly, if the visit of the physician had been confined to the limits incident to such purpose alone, his eligibility as a witness on behalf of the company might not be open to question. Without doubt a railway company with the utmost propriety may thus advise itself of the fact of injury and the character and extent thereof, in anticipation of a possible claim against it for damages And with that end in view it may send a physician to inspect and take notes, or otherwise inform himself of existing conditions But this can avail the company nothing unless the physician shall strictly retain his character as an employe of the company If, on request or on his own motion, he assumes to advise or administer treatment to the patient, and the latter in any manner acquiesces therein, the physician thereby casts aside his relation as an employe of the company and transfers his allegiance to the patient. In such instances a case is presented where one can not serve two masters at one and the same time The allegiance of the physician must be wholly on one side or the other It matters not, in this connection, who calls him in the first instance or who pays him He may present himself at the side of the patient on his own motion, and he may not expect, or in fact receive, pay If the physician assumes to advise or treat he should be put in possession of all facts necessary or material to enable him to do so properly If the patient acquiesce, he should have the right to, and should, communicate freely and fully, without fear of exposure or of having his confidence made common property It was to this end that the statute was enacted, and manifestly the purpose thereof may not be frustrated by proof that, at the time of rendering professional service, the physician was under control of employment to serve the interest of the person or company subsequently charged with responsibility for the identical injury he is called on or assumes to treat

1 —See abstract in THE JOURNAL, xlii, p 1585

2 **Pathogenesis of Chronic Gastric Ulcer**—MacCallum says that gastric ulcers may be produced by anything which causes necrosis of the mucosa of the stomach, and thus subjects it to the digestive action of the gastric juice In some cases the inception is very obscure The persistence of some of these ulcers offers the greatest difficulty of explanation It is probably true that all gastric ulcers tend to heal, but frequently they last a long time because new ulceration occurs in the same spot

3 **Anesthesia**—Sollmann considers the following anesthetics Chloroform, ethyl chlorid, ethyl bromid, gaseous anesthetics, petroleum ether, scopolamin morphin, cocain adrenalin, anesthesin, and yohimbin, describing their action and dosage

4 **Intestinal Obstruction**—Lobingier emphasizes the fact that the treatment of true intestinal obstruction is immediately and at all times surgical Late operative interference, due to late diagnosis or to procrastination, is the principal cause of the mortality A preliminary gastric lavage will do much to quiet and rest the patient when vomiting is an early and depressing symptom But the deceptive tranquility, which it sometimes brings, should not allay the fears of the attendant or induce him to believe that his first diagnosis was wrong Efforts to straighten out volvulus and intussusception by hydrostatic pressure must be made early and with great care, but that is doubtful surgery, and many a life has been lost from rupture and peritonitis when the manipulations were violent or continued until the intestine was gangrenous If the patient is seen early, before serious necrosis occurs, simple release of the constricting band will often suffice If destructive changes have occurred, and if the patient is very weak and unable to stand prolonged anesthesia, a primary enterotomy should be done, to be followed by an anastomosis as soon as the patient is sufficiently convalescent If the patient is sufficiently strong, immediate exsection of the gangrenous segment and anastomosis are indicated Early diagnosis is, of course, necessary The symptoms which appear early and on which the diagnosis depends, are obstipation, vomiting, persisting more than fifty hours, pain, more or less severe and constant, shock or collapse, meteorism, of localized character normal or subnormal temperature, a small rapid pulse and a leucocytosis between 15,000 and 20,000, with a strong reaction of indicanuria, if taken before the third day, and if the ileum is involved

6 **Preservation of Food.**—Richter considers the preservation of food by drying, freezing, sterilization and the action of chemicals He has devoted considerable time to the study of the preservation of artificial foods, and has worked out a method which he claims has yielded favorable results It is well known that gelatin, prepared by the hot extraction of bone and cartilage is a digestible proteid, forming no mean part of our regular diet Dried gelatin, even if contained in open packages, is not subject to decomposition, but remains unchanged for any length of time As a jelly, it soon become putrid Gelatin, if prepared in very thin films, will take up moisture from the atmosphere according to the dew point Richter has made practical use of this by constructing a self registering psychrometer and to preserve food, especially native albumins His process demands that the material to be preserved should be in solution For instance, the juice pressed out of raw meat, or a beef soup, containing all the necessary condiments, or strong tea or coffee or ox gall, is mixed with about 1 per cent of primary gelatin (commercial gelatin can not be used for the purpose on account of its glue like taste) After cooling, a jelly forms This is cut into thin films and dried in a cold air current until it becomes brittle The leave are then converted into a fine powder, which will keep indefinitely If not packed airtight it will take up moisture but not enough for decomposition to set in It may eventually cake, but the cake is brittle Insects find the dry substance too hard for their uses The powder is instantaneously soluble in luke warm water To insure the absence of septic or other organisms, the dry powder is heated to about 100 C before packing, or in the package Whole milk can not be preserved on this principle as oxygen can not be excluded After a while the powdered milk turns sour and exhibits a taste and smell of cheese Egg gelatin powder has excellent keeping qualitie for about ten months, when its solubility becomes less, though it remains perfectly digestible These preparations are not on the market nor are they likely to be manufactured for the present

15 *Immediate Repair of Injuries of the Pelvic Floor H C Coe
16 Case Presenting Unusual Difficulties in Diagnosis (Cholecystitis Simulating Appendicitis) Walter G Elmer
17 Large Fibroids of Uterus Complicating Pregnancy, Porro Operation William C Wood

9 **After-Treatment of Congenital Hip Dislocation**—Ashley and Mueller consider the after treatment of unilateral and bilateral congenital dislocations of the hip of group B, that have been corrected by the bloodless reduction method Their method is that advocated by Lorenz

12 **How to Check the Age Degenerations**—Loveland considers those changes in the arteries and smaller arterioles or capillaries incident to advancing years, and imperfect elimination or the gouty habit, in which the walls become thickened

stiffened, harder than normal, and later pass through the calcareous or atheromatous degeneration Many conditions are dependent on these changes as a fundamental cause, and a considerable majority of all deaths occurring after middle life may be charged to the account of degenerated arteries All the causes, save two, nephritis and old age, are removable. Hence, says Loveland, it is logical to suppose that after a removal of the cause the disease should be stayed in its progress He reports three cases, in which he followed a definite method of treatment, which point to the fact not only that there was a limiting of the process, but from the relief of certain symptoms, it would seem that, in some degree at least, an improved circulation in the parts supplied by the diseased blood vessels would indicate a certain amount of restoration in the diseased territory This improved circulation and nourishment might result from the absorption of thickenings which had narrowed the lumen of the vessels, or a bettered circulation, with more dilated arterioles and capillaries, affecting to some degree the hardened and thickened vessels with the rest, thereby allowing the passage of more blood Two of the cases were diagnosed as arteriosclerosis affecting the cerebral circulation The third case involved the coronary arteries The treatment of one case consisted of a definitely prescribed diet, cool bathing, and moderate exercise, strychnin, 1/30 gr, and mercury protoiodid, 1/6 gr, three times a day In the treatment of the second case electricity and sodium phosphate each morning, and 5 gr each of sodium salicylate and sodium benzoate, in a large glass of water, three times a day, were added The results in the three cases were excellent, but the author does not believe that the patients referred to will not die from some disease dependent on arterial degeneration Yet, it seems natural that the mode of living, which will result in so much improvement, if persistently adhered to, should leave the patients to be taken off by some acute disease or to "burn out" with old age

13 **Differential Diagnosis of Influenza and Acute Articular Rheumatism.**—Talmey cites his own case and questions the diagnosis of acute articular rheumatism made by a brother physician He bases his contention principally on his family history and his personal history He terms the disease with which he suffers, and which involves the muscular attachment around the joints, "rheumatoid" influenza

14 **Treatment of Status Epilepticus.**—Tremaine reports two cases in which she used intravenous saline injections with benefit, hence concludes that in this solution we have a valuable remedy for the treatment of status epilepticus

15 **Immediate Repair of Injuries of the Pelvic Floor**—Coe emphasizes his belief that by careful attention to these lesions immediately after labor the patient can be spared the necessity of subsequent operations for pelvic floor lacerations, prolapsus, etc He says that the modern accoucheur must be a thoroughly trained gynecic surgeon, who not only recognizes the true lesion at the time of its occurrence, but looks into the future and sees the patient's condition months after the injury

24 The Gastro-intestinal Crisis of Erythema Exudativum Simulating Appendicitis A. M Pond

18 **Arthritis and Its Treatment**—Ramson reports 28 cases of arthritis, 12 of which (43 per cent.) were gout The diagnosis is unquestioned, therefore it is interesting to note the relative frequency of gout Five of these 12 cases were acute gout, while the other 7 were of the chronic type of the disease Of the other 16 cases 5 were cases of rheumatic arthritis, 4 acute and 1 chronic, 5 cases of gonorrheal arthritis, 1 septic arthritis, 1 arthritis deformans and 2 cases of erythromelalgia The cases of acute gout were put on a milk diet, the joints were painted with a mixture composed of oil of gaultheria, 1 dram, ichthyol, 1 ounce, and then wrapped in cotton wool, oiled silk and a roller bandage Colchicin, 1/100 of a grain, was given every two hours, and, as a rule, could be repeated at two hour intervals for forty eight hours After the acute symptoms had subsided the drug was continued at intervals of four hours until the patient was discharged In the chronic cases the same method was employed in the case of inflamed joints Stiff joints were massaged and given passive movements and the patients directed to use the joints as much as possible—a very important factor in the treatment To affect his purpose Ramson employed an apparatus which he calls a "teeter," consisting of a piece of board twenty one inches long and eight inches wide About three inches from the lower end another piece of board about ten inches long is fastened at right angles to the first piece by means of a bracket. On the shelf so formed the foot of the affected leg is placed, the longer board being in contact with the posterior aspect of the leg The patient, seated in a rocking chair, rocks to and fro, thereby producing a greater or less amount of motion in the knee and ankle joints. It is an advantage over walking, as it not only keeps the weight of the body off the knees, but compels a much greater angle of motion The apparatus eliminates muscular rigidity and the movements of the joints are limited only by the actual structural changes, which are gradually overcome by persistent use of the "teeter" He also favors the use of colchicum in chronic gout The ichthyol bath is another measure which he has found useful in chronic cases. An ounce of ichthyol is put into a tub of water The water is fixed at a temperature of from 98 to 100 F, and the patient remains in the bath for from ten to twelve minutes The effect of the bath is the immediate relief of stiffness and soreness, which often lasts for forty eight hours, succeeding baths give longer periods of relief It is a good plan to precede the massage and movements of the joints by such baths, as there will then be much more freedom of movement and less soreness on manipulating Good food and tonics are, of course, essential

26 *The Interrelation of Medicine and Surgery in the Treatment of Gastric Ulcer Hugh Cabot and George S C Badger
27 Spindle-cell Sarcoma of Foot, Amputation Recovery Lung Metastases Death Autopsy Charles L Scudder

25 **Pulmonary Tuberculosis.**—Knight's paper is a discussion of the present treatment of tuberculosis by means of fresh air, diet and rest

26 **Gastric Ulcer**—The indications for the medical and surgical treatment of gastric ulcer are discussed by Cabot and Badger In acute bleeding ulcer operation is to be advised 1 After failure of good medical treatment to promptly stop acute hemorrhage 2 If, though the acute hemorrhage has been controlled, slight but frequently recurring hemorrhage persists 3 If, after the control of a large acute hemorrhage a second hemorrhage occurs within a short time It is not wise to defer operation until the patient is so far reduced as to render the risk of surgical operation very great. Medical treatment should be persisted in 1, in cases of acute hemorrhage not preceded by a train of dyspeptic symptoms and not showing a marked tendency to recurrence, 2, in cases in which acute hemorrhage is followed by apparent complete recovery, and in which the patient is free from serious annoyance from dyspeptic symptoms Operation is also indicated in perforating ulcers of the stomach, chronic dyspepsia without dilatation, which fails to yield to proper medical treatment, and cases of chronic dilatation of the stomach which fail to yield to medical treatment and are not due to a general visceral ptosis

28 *The Cycle of the Tubercle Bacillus A Preliminary Announcement. Stephen J Maher
29 *Clinical and Other Features of the Recent Epidemic of Cerebrospinal Meningitis Henry W Berg

30 *Mastoiditis with Paralysis of Facial Nerve, Recovery of Paralysis Following Operation Seymour Oppenheimer
31 Regarding Hamlet s Sanity John W Wainwright
32 *Illuminating Gas Poisoning, Its Rational Treatment Ernest V Hubbard

28 **Cycle of the Tubercle Bacillus**—Maher details his findings in the cultivation of a large bacillus which he has named *Bacillus maternus* and which he believes represents a mother shape of the tubercle bacillus He found the organism in a dark barn The individual rods from blood or milk cultures measure from three to eight microns in length and from three fourths to two microns in width One average rod would cover a dozen average tubercle bacilli It is a non motile facultative anærobe It forms a sediment and scum on bouillon and renders it turbid It forms an opaque, non spreading colony on the surface of agar or glycerin agar in tubes or petrie dishes Deep colonies in agar resemble those of anthrax It grows at room temperature, and its spores resist more than 100 degrees of moist heat for an hour It digests but does not curdle milk It forms a sunken colony in blood serum and only slightly digests the serum It quickly dissolves gelatin and shrinks to smaller rods On ammoniated gelatin the rods are somewhat stouter, with a growth of diplococci After fifty hours on sugar gelatin the colony consists of many large spores and an immense amount of acid fast amorphous spore matter, which fills to bursting many of the rods, and which is also found in various rounding shapes, free in the microscopic fields On potato, a dry opaque gray or lemon colored growth is formed Maher has not yet been able to grow a pure colony of *Bacillus maternus* from tubercular sputum, but is satisfied that he has several times recognized individuals and groups of this organism in the fields of blue biscuits and pus nuclei and acid fast rods, with which we are all familiar He has isolated what seems to be a pure culture of *Bacillus maternus* from smegma and also from the spleens of guinea pigs dead with tuberculosis

29 **Cerebrospinal Meningitis**—Berg's usual method of treatment consists of repeated lumbar punctures only when, after a period of improvement, the temperature rises again and symptoms of increased intraspinal and intracranial tension occur If the cerebrospinal fluid flows from the canula in a continuous stream under tension, the withdrawal of from 15 to 30 c c of fluid will do much good If it escapes drop by drop the puncture will have no effect from a therapeutic standpoint Sodium iodid is given in considerable doses, from 5 to 10 grains every three hours to a child over a year old, from 15 to 20 grains every three hours to adults Adults also receive 15 grains of mercuric ointment by inunction in the back of the neck twice daily, until the gums are red In children with open fontanelles, the oleate of mercury in proper doses is rubbed into the anterior fontanelle In older children the mercurial ointment is rubbed into the back of the neck and spine, in pieces as large as a bean, several times a day Icebags should be applied to the head, neck and spine With these methods, together with the treatment of symptomatic indications, 40 per cent of recoveries may be expected When the temperature goes above 103 F he uses a warm bath, temperature 80 F, in which the patient remains five minutes The temperature of the bath is then raised to 90 F and the patient allowed to remain five minutes more Care must be taken to prevent bed sores, local infection of the skin, eyes, ear, nose and throat The patient should be placed in a large light room, with plenty of air space and proper ventilation Sun light is desirable, as it is one of the most powerful antidotes to the bacteriologic cause of this disease

30 **Mastoiditis and Facial Paralysis.**—Oppenheimer reports two cases of mastoiditis with paralysis of the facial nerve, both of which recovered after operation He offers nothing new

32 **Illuminating Gas Poisoning**—Hubbard reports a case of this kind in a woman, aged 75, in which, following venesection, abdominal hypodermoclysis was done The pulse, which had been thready and barely perceptible began to improve within a few minutes The injection was continued until 1,200 c c had been given After an hour the patient showed the first signs of returning consciousness and by nightfall she had quite recovered Venesection removed much of the poison and the saline infusion diluted the remaining poison, and furnished the heart with fluid to continue its work until the blood making organs could furnish a new supply The venesection must be performed early in order to ensure success The amount of blood to be withdrawn will vary in the individual case When the pulse becomes feeble it is time to stop The saline infusion is injected until the radial artery at the wrist gives a full steady beat If four or five hours have passed with no evidence of returning consciousness, a second venesection may be done, but with great caution

38—This article has appeared elsewhere See THE JOURNAL of September 3, 1908, p 697

39—Ibid, title 65, p 697

40 **Primary Malignant Tumor of Adrenal Glands.**—Amberg reports a case of this kind occurring in a child two months old The parents first noticed a slight swelling of the abdomen, which increased rapidly On examination he found the enlargement, some edema of the abdominal walls and the superficial veins much distended On palpation, a hard smooth mass was felt, chiefly in the right side of the abdomen, extending from the costal margin down to the right inguinal region, passing deeply into the right flank and filling up the whole space between the ribs and the iliac crest In the right inguinal region a firm edge was felt, which could be traced from Poupart's ligament toward the navel, passing below the navel and then gradually ascending To the left of the navel a notch could indistinctly be felt, but it was not possible to distinguish two separate masses The length of the tumor mass in the median line was 16 cm, the distance from the interclavicular notch to the umbilicus was 21 5 cm, and the greatest circumference of the abdomen was 46 cm The uniform tumor apparently represented the liver The red blood corpuscles numbered 2,800,000, the white 11,000, of which 79 per cent were polymorphonuclears 18 5 per cent small mononuclears, 2 3 per cent large mononuclears and transitionals, and 0 2 per cent eosinophiles The child died in convulsions six days after it was seen the first time The autopsy disclosed a tumor of the left adrenal gland and a very much enlarged liver The liver was cirrhotic and fatty, and contained numerous masses

of cells, the same as those in the adrenal tumor The tumor was apparently a malignant one, taking its origin, probably, from the medulla of the adrenal gland The growth in the adrenal itself was too far advanced to give any information regarding its origin Morphologically, the tumor may be classed as a carcinoma or as an alveolar sarcoma

54 Influence of Growth on the Course and Treatment of Congenital Clubfoot. A. B Judson
55 Report of Experiments to Determine Whether Plaster of Paris Contracts or Expands in Setting J Torrence Rugh

43 **Technic of Neuroplasty**—Experiments on animals, as well as operations on man, have proved that it is possible to establish reciprocal connection between two different nerves Splitting and grafting of nerves have also been performed on man, and, in some cases, with good results Spitzy carried on experiments for the purpose of determining the kinds of paralysis that are observed most frequently, and the best methods for correcting the same. Dogs were used, and his results were good. The first rule is most scrupulous asepsis and a careful closure of the incision The first experiment consisted of grafting the perineal nerve on the tibial Clinical tests showed a good result Microscopic sections made from tissue taken from the site of union showed distinctly the passing of nerve fibers from the stem of the tibial nerve into the implanted peripheral stub of the perineal Other experiments were equally successful Neuroplasty should be resorted to in cases of paralysis where the period of spontaneous regeneration has passed and when other therapeutic measures have proved useless, if the interruption of the conductivity can not be remedied by means of an operation (excision of the scar, primary or secondary suture, neurolysis) Neuroplasty is to be recommended in any case before an extensive tenoplasty is attempted. The author expresses the opinion that these plastic operations are, at all events, worth a trial The advantage of the method is that it does not interfere with any other methods known and practiced, but is an addition and an increase to our therapeutic resources

45 **Final Results in Tendon Transplantation.**—Hoffa says that in order to achieve a good result after a tendon transplantation four conditions are necessary 1 Perfect asepsis 2 Prevention of hemorrhage. 3 Healthy muscle material 4 the tendons must be united under certain tension Not much can be expected from an operation on a limb totally paralyzed The leg cannot be made to functionate again, but the patient can be freed from the annoyance of depending on orthopedic apparatus This can be done in a great number of cases In other cases a certain amount of tendinous fixation of the joints can be produced which still allows a certain amount of functional activity In some cases it is possible to bring the muscle back to life These are the ones in which the regenerative powers are still present in the muscles By shortening the muscles their elasticity and tone is restored. As to the method of operating, Hoffa believes that the best results can be obtained by combining the operation of Nicoladoni with that of Lange. Of course, the factor of individual experience in the performance of these operations counts for much The most important essential for the success of the operation is to obtain the highest possible tension with an over correction of the deformity This necessitates the correction of the deformity before operating The longer and more careful the after treatment the better are the final results Hoffa refers briefly to the good results he has obtained in paralytic club foot, shoulder joint paralysis, spastic contracture of the forearm and elbow, and paralytic talipes calcaneus

46 **Infantile Paralysis of the Lower Leg**—The authors have made a comparative study of the results of various surgical operations for the improvement of the conditions found in the lower limb as a result of infantile paralysis in 50 consecutive cases, with a view to determining what operations offered the best prospect of a useful limb As the operations were performed by various surgeons, the equation of personal technic was practically eliminated It is important to remember, however, that all these cases were dispensary patients, and were cared for in the dispensary after the operation The present status of 14 cases could not be obtained These statistics would seem to show

1 That in all cases where an attempt was made to restore the balance of muscular power by means of a transference of either the peroneus tertius or the extensor longus hallucis the transplanted muscle has failed to hypertrophy to an extent sufficient to cause any benefit (Eleven such cases fail to show any improvement.)

2 That simply shortening the extensor tendons in cases of equinus even aided by transplantation of the flexor longus hallucis is of no prominent benefit (Two operations, both followed by relapse)

3 That where the peronei are inserted into a paralyzed tendo Achillis for the relief of calcaneus the result is usually disappointing (Five operations the result in four being distinctly poor, and in one only fair)

4 That, in cases where the peronei are transplanted to the inner side of the foot for the correction of a valgus deformity the results are slightly better, but there are relatively few successes (Six operations. Two results were poor, two fair, and only two good)

5 That, where a portion of the tendo Achillis is transplanted to the extensor side of the foot for the relief of equinus the condition is distinctly improved (Two operations that in which the tendon was joined to the common extensor giving a stronger foot when it was united with the anterior tibial)

6 That the best results following tendon transplantation were in cases where the whole or a portion of the anterior tibial was transferred to the outer border of the foot for the relief of equino varus (Three operations showing two good results and one that was fair The latter was performed by the so-called Lange method of lengthening the transplanted tendon by means of braided silk The silk acted as a foreign body and sloughed, thus preventing a good result. Experience with cases that are too recent as yet to report would seem to show that where the transplanted tendon can be given a sub-periosteal insertion in the cuboid the functional result is better than when it is inserted into the tendon of the peroneus brevis All the latter cases promising well)

7 That astragalectomy uniformly yields a good useful foot (Three cases, and all successful)

8 That the results of arthodesis of the tibio-astragaloid joint are, as a rule, excellent. (Nine operations, with seven good results In one of these cases complete immobilization was not secured at the first operation, but a second gave a most excellent result. In the other there was no improvement, due probably to a failure to remove a sufficient amount of the articular cartilage A somewhat stronger foot was found in the cases of arthrodesis than these where astragalectomy had been performed.)

The conclusion would seem to be that, while tendon transplatation may in certain cases yield a satisfactory result, the selection of cases for this operation should be much more careful than it was three or four years ago and that for the great majority of hospital cases either astragalectomy or arthrodesis offers by far the greatest promise for obtaining a strong useful foot several years after the operation

47 **Bier's Treatment in Joint Tuberculosis.**—Freiberg discusses Bier's "congestive method" in the treatment of joint tuberculosis Originally, the congestion produced was as great as possible, the parts became not only turgid with venous blood, but also cold Considerable pain had to be endured by the patient, and the constricting bandage was applied for hours at a time Bier has modified his method so that all possibility of damage by it would seem to be removed As at present advocated, the congestion should never pass beyond the "hot stage" The patient should feel no pain, the treatment should not be more than one hour daily Freiberg has found that by using a bandage of elastic cotton webbing the degree of congestion is controlled more easily than when the rubber bandage is used. In patients of ordinary intelligence the proper application of the bandage is very soon learned, so that it can be applied at home. In conjunction with the Bier method, Freiberg insists on immobilization and protection, the same as heretofore. He regards the method as an adjuvant to the re

sources long at our disposal, but by no means destined to supplant them The improvement in results is unquestionable, but not so great that he would be willing to trust to congestion alone The congestion method of treatment has an influence on muscular atrophy by accelerating the reparative process The possibility of cure by congestion, says the author, is never to be ignored It would seem of special importance in diseases of the wrist and ankle, but to attain success by means of Bier's method requires time, and patience, and care in detail Unreasonable things should not be expected of it Three cases are cited in which the method was used successfully

65 **Bacteriological Study of Scarlet Fever**—Schamberg and Gildersleeve examined bacteriologically a series of cases of scarlet fever The cultures were made between the second and sixth day of the disease The blood of twenty cases was examined and negative results obtained in all Streptococci and staphylococci were found in the vast majority of the cases Cultures were made from the throats of 100 apparently well persons, and streptococci were found in 82 per cent Both streptococci and staphylococci undoubtedly are frequently concerned in the complications of scarlet fever, but are not to be looked on as the specific agent The diplococcus described by Class as the cause of scarlet fever was found by the authors in a comparatively small per cent of the cases examined. They do not regard this organism as bearing any etiologic relationship to the disease They believe that the failure to discover the specific cause of scarlet fever may have been due to the fact that almost exclusive search has been made for vegetable parasites and not for animal parasites The findings of Mallory, of protozoa like bodies in the skin of scarlet fever patients, will doubtless stimulate research along these lines

79 *Surgical Treatment of Varicose Veins C H Mayo.

73 **Nondiphtheritic Membranous Angina**—Wilson divides the non diphtheritic pseudomembranous anginas into several groups, each of which is a more or less distinct clinical entity associated with a species of micro organism either alone or in great preponderance These nondiphtheritic anginas are important not only because of the necessity of differentiating them from diphtheria, but also because they are frequently transmissable, and their treatment should vary according to the micro organism present Careful clinical observations, in connection with full bacteriologic investigations, should be made in each case In order to determine as early as possible the etiologic factor in anginas, cover slip or slide preparations from the membrane, as well as cultures on diphtheria media, should be made by the physician on his first visit These should be dried without healing, then fixed by heat, and either stained by the physician, or sent to a laboratory with the culture for further examination Wherever possible, more extensive bacteriologic investigation should be made Among the associated organisms found by Wilson were streptococci, diplococcus pneumoniæ, Friedlander's bacillus, spirillum of Vincent, and blastomyces He believes that the blastomyces is a much more common cause of angina than is believed These cases present a clinical history of onset with chill, somewhat rapid rise in temperature, malaise and considerable prostration The tonsils are congested, swollen, and rapidly become covered by a thin, grayish white membrane, which in most cases extended forward from the tonsils over the anterior faucial pillar, and in some cases upward, involving the uvula and soft palate The membrane does not yield readily to local treatment, to silver nitrate, iodin, lactic acid, carbolic acid, or formalin Antitoxin has been used without any effect on the membrane Two cases in which no other organisms were obtained in culture proved fatal Blastomyces were found alone in 136 cases, and in 97 cases they were associated with bacillus diphtheriæ The organism grows abundantly on the ordinary laboratory media, forming a thick, white and moist growth In fluid media the growth sinks to the bottom of the tube in a few days Glucose and maltose are fermented but without the formation of alcohol No fermentation occurs in lactose The organism stains readily, but unevenly, showing nuclei, vacuoles, and chromatophilic granules No spore formation has been produced

76 **Injuries of the Kidney**—Courtney discusses this subject,

reports four cases, and concludes by saying that the inference to be drawn is that nephrectomy should only be performed early when the renal vessels are known to be torn, or when there is such unmistakable disorganization of the kidney structure as to make it reasonably certain that resumption of function can not be expected

77 **Pneumonia**—Conley gives a short review of the treatment of pneumonia for the last fifty years, but offers nothing new

79 **Surgical Treatment of Varicose Veins**—Mayo is of the opinion that the essential predisposing cause of varicose veins is a congenital defect in the vessels or their innervation, which, in some cases, may be aggravated by occupation, injury, childbearing or constipation He favors a partial Schede operation or oval incision above a large ulcer combined with excision of the ulcer and skingrafting At the same time, the Trendelenburg operation, or the more extensive excision of the internal saphenous vein from the upper third of the thigh to a point six or eight inches below the knee, is also performed The removal of short areas of veins is reserved for those cases with involvement of the veins of the posterior thigh or the external saphenous In a very few cases where the veins are enormously and irregularly dilated, the stripping process, described below, is impossible through the whole extent of the saphenous The Bristol method is then used as an adjunct to the enucleation treatment. The author's method is as follows The vein is sought for and severed in the upper third of the thigh The proximal end is ligated, the lower end is clamped an inch from the end, which is passed through the ring of the enucleator (a ¼ in ring of steel with a long handle, not unlike a blunt uterine currette) or placed in the tube of the forceps (which are hollowed out in each blade so as to form a long tube, when closed, about ¼ of an inch in diameter) and the clamps are transferred to the end of the vein By gentle pushing force the ring or forceps is pushed down the vein, held under tension for six or eight inches, tearing off the lateral branches when the point of the instrument is forced against the skin from beneath, and a small incision made in the skin to the ring or forceps, which is pushed through the opening holding the vein in it like a thread in a needle eye. The vein loop is drawn out of the opening and also from the instrument, which is removed and re-threaded and again forced through the new skin opening, following the vein, and is pushed down to a lower point where a small incision is again made and the same process of removal repeated. The small lateral branches are torn off and, as a rule, have enough muscle structure to close themselves Below the knee, the branches are larger and the vein is more adherent, so that a short distance can be traversed Hemorrhage is avoided by position An ordinary gynecologic standard is placed in position and the leg raised in straight or extended position and supported by the ankle. This renders the limb partially bloodless and secures elevation and accessibility of the field of operation More than momentary hemorrhage can be checked by a small pack, or an assistant can check it by pressure pad held against the skin over the region from which the blood escaped from the vessels This method has reduced the time for operation very considerably, and has placed it in the class of relatively trivial operations, although sepsis may render it one of the most serious

80 *Syphilis of the Stomach. Charles F Hoover
81 *A Year's Experience with the Convulsions of Children D S Hanson.
82 Eclampsia and Its Treatment. Martin Stamm.
83 Paranoia. E C Brown

80 **Syphilis of the Stomach.**—Hoover says that the varied characters of syphilis of the stomach, and the symptoms it may produce, have so many points in common with other diseases that the diagnosis during life must rest on the therapeutic test Three cases in point are reported, each presenting entirely different symptoms In none of the cases was there a palpable tumor or area of maximum tenderness. Nothing abnormal could be detected in physical examination as far as the stomach was concerned In two cases the only symptoms referable to the stomach were pain, and vomiting, after the ingestion of food Although two cases gave a clear history of syphilis no evidences of syphilis were apparent on physical examination The third case had a saddle nose and perforated soft palate In these cases it is important to make a diagnosis so that proper treatment can be followed Unless the physician is strongly impressed with the possibility of syphilis being the etiologic factor, iodid of potassium will not be given on account of its irritating properties to the stomach When in doubt, give iodid of potassium, is a maxim easily followed when the stomach is not at fault But the administration of iodid of potassium in a doubtful case in which gastric pain and vomiting are the conspicuous symptoms, is abhorent to the mind of the therapeutist unless the idea of syphilis is paramount in his speculations

81 **Convulsions of Children**—Hanson details his experience with the convulsions of children, making special reference to the etiology of the cases observed, and emphasizes the importance of chloroform inhalations, chloral enemata, hypodermic injection of morphin, and the inhalation of oxygen in the treatment of these cases, each to be used as indicated

91 *Treatment of Fractures and Dislocations According to Modern Principles. J B Fattic
92 *The Yeast Poultice with Instances of Its Successful Use E J Kempf

85—*This article* appeared in The Journal of July 16, p 164

90 **Intestinal Obstruction**—Bowers discusses the etiology dynamics, and symptoms of intestinal obstruction, and reports two cases, one a man aged 45 years, in which a Meckel's diverticulum was the cause of the obstruction, the second case a boy 3 years old, in which the obstruction was caused by a portion of the bowel being forced through a slip in the mesentery An end to end anastomosis with the Murphy button was performed in the first case, and the patient recovered The second patient died from the results of a very extensive gangrene of the bowel

91 **Points in Treating Fractures and Dislocations.**—This is a general discussion of the subject, as indicated in the title, in the course of which Fattic sounds a note of warning with reference to the improper use of the *x* ray in determining whether or not a fracture has been attended to properly Patients sometimes are inclined to base their intention of bringing suit for malpractice on the ground that the fracture was not set properly because the *x* ray's shadow shows badly and oftentimes gives the appearance of deformity when for all practical purposes it was perfect In this way, in incompetent hands, the *x* rays may wreak injustice on innocent practitioners

92 **Yeast Poultices**—Kempf reports six cases of sepsis and gangrene in which the yeast poultice was used with satisfaction His method is as follows Beer yeast, one quart, corn meal, finely sifted, one pint, mix and place the mixture near a fire until it rises Then mix the thin raised dough with about two ounces of finely powdered charcoal Apply the mixture on a thick cloth directly to the affected part and renew every twenty four hours It becomes dry and adheres to the parts but can be removed readily with warm water This is a most efficient antiseptic poultice for the treatment of gangrene, erysipelas, eczema, ulcers, etc

1 **Tremors.**—Mott classifies the tremors arising in disease as follows 1 Organic disease of the nervous system 2 Tremors due to poisoning 3 Tremors in infectious diseases 4 Neuropathic tremors of degenerates 5 Tremors of neuroses (*a*) exopthalmic goiter, (*b*) paralysis agitans, (*c*) neurasthenia, (*d*) hysteria No classification is quite satisfactory Very often the tremor is polymorphic—at one time, or in one case, existing only during repose, in another disappearing during rest Several diseases may present a fine vibratory tremor, such as Graves' disease, neurasthenia, emotionalism and alcoholism The author believes that tremor is due to a disturbance of the normal innervation currents passing from the spinal motor neurons to synergic groups of muscles, whether these are in action or in passive tonic contraction A functional or organic disturbance of the nervous structures which regulate and adjust the outflow of the innervation currents from these spinal motor neurons would serve as a cause of tremor Tremors should be investigated by a consideration of the following questions 1 Are the tremors local or general? 2 Are they continuously present, or only transitory and called for by certain circumstances, such as emotion, attention, irri

tation or bodily fatigue? 3 Do they occur in the part at rest? Do they cease during sleep? Are they provoked by intentional movements? 4 Is the amplitude of the oscillations extensive or not—in other words, is the tremor coarse and obvious or fine and only discoverable by careful examination? 5 Is the rhythm quick (8 to 9 oscillations a second) or slow (4 to 5 oscillations)?

3 Hemiplegia With Cerebral Tumor—Williamson calls attention to the value of hemiplegia of gradual onset as a sign of brain tumor, even when optic neuritis is absent, or when optic neuritis, headache, and vomiting are all absent Stated in other words—provided there are no indications of cerebral abscess—progressive hemiplegia, or hemiplegia of gradual onset, in which weeks or a few months elapse before the paralysis is complete, may be regarded as strong evidence of cerebral tumor even when optic neuritis is absent, or when optic neuritis, headache and vomiting are all absent.

5 Ulcus Carcinomatosum.—Moynihan reports one case of malignant disease of the stomach in which both the clinical history and microscopic examination showed that the origin of the growth was a chronic ulcer

7 Unusual Variety of Pleurisy in Children—Riviere reports six cases of loculated effusion occurring over the middle lobe and closely simulating other pathologic changes occurring in children in the same situation, such as pneumonia with subsequent effusion at the base, fibrosis of the middle lobe, pulmonary or glandular tuberculosis, pulmonary collapse and chronic lung disease in the opposite side of the chest, either tubercular or bronchiectatic in nature The *diagnosis* was *not* confirmed with the exploring syringe in any of these cases, the author not deeming such a measure justifiable under the circumstances

15 Notification of Consumption A. Jefferis Turner

11 Splenectomy—Stirling reports two cases of splenectomy for splenic pseudoleukemia that recovered from the operation, but makes no mention of their subsequent history Both cases were alive one month after operation, and the blood findings had improved remarkably The red cells in one case numbered 4,820,000, and in the other 4,600,000, leucocytes, 8,000, hemoglobin, 85 per cent The author considers the following indications for splenectomy Malarial spleen, splenic pseudoleukemia, splenic leukemia, Banti's disease, wandering spleen, abscess of the spleen, rupture, sarcoma, and possibly hydatids of the spleen

12. Six Cases of Splenic Anemia—These six patients stood in the relationship of three sisters and one brother, and the latter's son and niece. Two brothers and ten cousins have not been examined to determine whether they are or are not affected There was no family history of congenital syphilis or of acquired syphilis, except in one instance The ages of the patients were 28, 19, 23, 30, 7 and 10 respectively Splenectomy was performed in two of the cases who were still doing well one year after the operation.

17 Alexander's Operation.—McKay describes, in full, Alexander's operation and concludes as follows Retroflexion of the uterus in virgins and married women when there is no prolapse and when there are no adhesions present is the condition for which this operation is most suitable Retroversion of the uterus he considers a suitable condition, for, though a retroversion may cause no symptoms, still if the uterus is allowed to remain in its abnormal position the abdominal pressure may in time convert the retroversion into a prolapsus or a retroflexion If after performing the curettage he finds the uterus retroverted he shortens the ligaments as a routine practice If with retroflexion or retroversion there is slight prolapse of the uterus, shortening the round ligaments is a good operation when used in conjunction with amputation of the cervix and colporrhaphy This allows the uterosacral ligaments (the chief supports of the uterus) to regain their tone In well marked cases of prolapsus the operation may be done if the woman is in the child bearing period, if the menopause is passed, or if near at hand, ventrofixation is the proper operation for severe prolapse, though of late he has adopted a plan of removing the uterus by vaginal hysterectomy It is such an easy matter to explore the ovaries and tubes through the internal ring that he has adopted this method in preference to the median incision when he wishes to remove a small ovarian cyst or a hydrosalpinx

19 Typhoid Perforation—Turner says that when a recognizable *perforation* occurs during an attack of typhoid fever an operation should be performed, and at once

20 Gunshot Wounds of the Abdomen.—Verco says that although military authorities are agreed to leave abdominal bullet wounds alone, as they find that this treatment gives the greatest percentage of recoveries, yet in civil cases, the surroundings being favorable, the abdomen ought to be opened as soon as possible after the injury, and the wounds of the viscera, if any, sewn over In military practice the wound is often inflicted with the stomach and intestines comparatively empty, and hence there is little danger of leakage. Just the opposite is true of most civil cases Again, when the stomach and intestines contain much fluid the "explosive action" of the bullet makes a much larger hole. Furthermore, it should be remembered that in the case of missiles fired at close quarters there is much tearing of the hollow organs, and not the clean penetration that occurs in a wound from a missile fired at a distance

24 25 Epidemic of Infantile Paralysis.—Wade details his observations made on 34 cases of epidemic infantile paralysis, 16 of them males and 18 females The youngest patient was 13 month olds, the oldest 7 years In each case the onset was sudden, the disease being initiated by anorexia, fever and vomiting In 2, the vomiting was absent, in 3, the attack was ushered in with fever, vomiting and diarrhea, in only 1 case were there convulsions, and this was in an epileptic, in 1, the paralysis occurred during pneumonia, in 1, during measles, and in only 1 case was there apyrexia The fever in each case persisted for from four to ten days, ranging between 100 and 102. The most marked symptom was pain in the affected limbs, and this was present in 28 out of the 34 cases. Marked tenderness existed in the affected muscles and persisted for some time, in one case lasting two months, and in most cases from three to four weeks In only two cases was tenderness absent The muscles of the limbs which were affected in all cases, either alone or in conjunction with others, belong without exception to the extensor groups, and were the trapezius, supraspinatus and infraspinatus, deltoid, triceps and extensors of the fingers in the upper limb, while in the lower were the quadriceps, peronei and extensors of the foot. The flexors and adductors were never involved alone, but only as a part of the general paralysis of the limb With the onset of paralysis the affected muscles became limp and flabby, but no wasting was noticed A certain amount of recovery is the rule, but in every case there are some muscles or groups of muscles that show no indication of it Recovery is slow, does not begin until about six weeks afterward, and in some cases improvement is still going on after four months The superficial skin reflexes and the knee jerks were present or not, according as their corresponding muscle was paralyzed or not. Kernig's sign was present in 3 cases, in each case the erector spinæ

was involved During the acute attack, before the onset of the paralysis, the essential factor to help in arriving at a diagnosis is the tenderness of the muscles After the appearance of the paralysis, it has to be distinguished from multiple neuritis, which may be done by its acute onset, the want of symmetry and the permanency of the paralysis The treatment must be expectant When the paralysis is established, massage and the use of the constant current is indicated, but must be delayed until the tenderness has become diminished

Litchfield gives a brief summary of 25 cases observed by him The treatment consisted of keeping the paralyzed limbs warm, massage and measures to prevent deformity, the latter in some cases necessitating the use of splints

26 **Epidemic Polyneuritis**—Blackall reports six cases of epidemic polyneuritis, all between the ages of 3 and 18 The disease comes on gradually The patient feels out of sorts for one day, and the next is very ill and complains of headache Vomiting now usually comes on, together with pains in the abdomen, more especially in the neighborhood of the cecum The tongue is thickly coated and the bowels are constipated Temperature, 101 or 102 Pulse is slightly and the breathing considerably accelerated At this stage of the attack it is apt to be mistaken for appendicitis, but there is an entire absence of muscular rigidity when pressure is made over the seat of pain A day later the vomiting is less severe or gone, the pain in the abdomen is less, but pains are felt all over the body, more especially in the limbs At this stage the disease simulates subacute rheumatism, but is differentiated by the absence of swelling or heat or weakness locally, and the absence of pain in the joints. The pains in the limbs become less, but the loss of muscular power becomes absolute The reflexes are lost The *tache méningéale* is well developed There may be retention of urine. The breathing is short and gasping and is entirely diaphragmatic The patient speaks with difficulty The temperature remains up from a week to three weeks The paralysis gradually disappears, but in three cases out of four that regain their usual health the patients are unable to extend one arm from the body, although they can flex, extend and rotate the forearm, and the power of grasp is not diminished The muscles that cover the scapula, the shoulder joint and the arm waste away, but the muscles of the forearm are not affected In two cases the right arm, and in one the left, was affected The time that has elapsed since recovery from the illness is too short to offer an opinion as to whether the paralysis is likely to be permanent

27 **Pneumothorax.**—This was a case of suppurating hydatid cyst, about the size of a small orange, filled with daughter cysts

28 **Indications for Dechloridation**—Dechloridation or suppression of the ingestion of salt is merely treatment of a single symptom, the retention of salt in heart or kidney disease But this retention has so many consequences that it is of great clinical importance, especially in Bright's disease and also in cases of cardiac edema, ascites, hyperchlorhydria and even in certain cutaneous affections with exudation Javal gives the detailed history of 2 patients with severe Bright's disease under the influence of intermittent dechloridation The curves are instructive in several respects They show that theobromin is valuable as an adjuvant but is unable to take the place of dechloridation Also that the milk diet is unnecessary—*all that* is needed is a diet free from salt This alone will frequently accomplish all that is needed or required and any medication is superfluous and hence more or less harmful The changes in the body weight parallel the fluctuations in the salt retention Daily weighing is thus an important means of detecting slight edema and its preliminary phases, long before they become clinically evident Abrupt increase in weight is pathognomonic of retention of salt and its retinue of fluids Each 5 or 6 gm of salt retained holds back with it a liter of water, equivalent to a kilogram of weight that is, 2 2 pounds By daily weighing we learn the exact condition of the retention of salt and can regulate the amount of salt allowed in the diet to correspond with the amount retained

29 **Otology in the Medical Curriculum**—Politzer's article was one of those presented to the recent International Congress of Otology, which voted affirmatively on his conclusions These were to the effect that every faculty of medicine should have a chair of otology and that it should be made one of the compulsory branches of medical instruction

31 **Diet in Nephritis.**—Köster's article was published in 190 and proclaims the necessity for a strict milk diet in acute nephritis, in case of uremic symptoms and during exacerbations of chronic nephritis When the excretion of albumin and the sediment of the urine has attained a fixed amount, the régime can be varied without danger He advises interposition of a few days of milk diet occasionally

32 **Differential Diagnosis of Yellow Fever**—Lengua comments on the difficulty of differentiating a severe case of pernicious malarial fever from fulminating yellow fever He describes a case in which a man previously healthy suddenly developed symptoms typical of fulminating yellow fever, with the sole exception that there was no icteric aspect This latter symptom, however, is not invariable in yellow fever He diagnosed the case as one of pernicious malaria solely from the antecedents of the case The fever had come on suddenly two weeks after working in a marshy field, and symptoms of tertian malaria had been noted in the interim, the health having always been good before this time. He rapidly recovered under vigorous quinin medication

33 **Absorption and Elimination by Leucocytes of Foreign Substances.**—Among the points emphasized in this study of the rôle of the leucocytes in respect to foreign substances, we note that Maurel affirms that the amount of a poison necessary to kill the animal is the same proportion as is necessary to kill the single leucocyte Opium paralyzes the leucocytes and prevents phagocytosis, consequently it is illogical to administer it in affections in which the co operation of the leucocytes is desired The leucocytes incorporate the foreign particles and digest them if possible If not, the digestion is completed in the lymphatic ganglia where the leucocytes carry them, or the foreign particles accumulate in the ganglia if absolutely insoluble. Labbé reviews a large number of the latest theoretical and experimental researches on this subject They demonstrate that we need not hesitate to use insoluble substances in therapeutics They may act less rapidly, but they are utilized in time by the intermediation of the leucocytes, and, although somewhat late, their action is all the more durable The part played by the leucocytes in draining the system of injurious substances and transporting them out of

the organism, rehabilitates the old method of fixation abscesses as a therapeutic measure of great value in certain infections and intoxications

34 **Levurargyre.**—This term is a combination of the words meaning yeast and mercury, and is applied to a mercurial nucleo proteid extracted from brewer's yeast grown in a wash containing a certain proportion of bichlorid of mercury It thus combines the properties of yeast and mercury and seems to display therapeutic action against the general cutaneous manifestations of syphilis Jullien qualifies the clinical results obtained with this new product as very encouraging

37 **Ships and Mosquitoes**—Dupuy's investigations showed that both steam and sailing vessels are liable to have mosquitoes blown or brought on board They find congenial lurking places in the cabins and hold. Mosquitoes bred on board can not be infected, but those that come on the ship in an infected port are liable to be dangerous to man He advises that ships should dock where they would be inaccessible to mosquitoes, and also that doors and windows should be kept screened, especially toward evening As soon as the ship is in the open sea, pyrethrum powder should be burned in the cabins, and they should be energetically aired and ventilated The Clayton apparatus should be used in the hold, and again on arriving

38½ **Simulated Perforation in Typhoid.**—The classic arguments in favor of operating in case of typhoid perforation are re enforced by Rochard's experience with a case in which the assumed perforation had no existence in fact, but the laparotomy had evidently a curative action A convalescent from typhoid suddenly presented the typical syndrome of intestinal perforation, and was operated on the third hour The large intestine, duodenum, stomach, and gall bladder were carefully examined but found apparently sound, the only abnormal appearance being exaggerated vascularization of the transverse colon Nothing further was done and the abdomen was sutured, the patient recovering rapidly without complications He cites two similar cases published in France in which at the laparotomy nothing was found to explain the symptoms of typhoid perforation, except slight redness of the small intestine in one and congestion with false membranes at the ileum in the other Rochard thinks that the congestion observed was a sign of incipient peritonitis, and that the severity of the symptoms induced was due merely to the extreme sensitiveness of the peritoneum in persons convalescing from typhoid The uneventful recoveries in these cases, the manifest curative action of the laparotomy alone, and the inevitably fatal outcome in case of unoperated true perforation impel to prompt surgical intervention

41 **Danger of Apparent Death.**—Icard of Marseilles France, has been investigating every case of resuscitation after apparent death of which he has learned during the last twelve years The lay press frequently publishes stories of this kind, but in nearly every instance inquiry of the parties interested showed that the stories had no foundation Even a single authentic case of burial alive should impose on the conscience of every physician the most scrupulous care before he signs the certificate of death Icard has collected eleven cases in which the physician's certificate of death was followed by the revival of the subject later, and another case in which there was no medical opinion The revival occurred before burial in every instance. He also knows of other cases, but they lack the strict scientific data of the series he describes in detail In one case the revival occurred in the mortuary room of a German city where the dead are kept by law until evident signs of putrefaction He includes in the list an instance personally observed A woman had taken lodgings at a hotel and sent for her lawyer to change her will He arrived and went to her room with a bell boy There was no reply to their knock, and when the door was opened she was found inert and insensible in the bed, the body cold and the limbs rigid. The police were notified, the family informed, and Dr Icard was sent for to deliver the certificate so that the corpse could be removed When he arrived, the hotel keeper met him grumbling at his delay, and urging him to sign the certificate at once, as the presence of a corpse in the hotel was ruining the business Icard found some warmth in the body, and perceptible but very faint heart beat, and the patient was soon revived Hotel keepers are in such haste to hurry a corpse out of the building that they are liable to antedate the hour of death, and the physician should be on his guard especially in such cases In another instance the physician attending a prominent citizen was convinced that death had arrived and so notified the family circle The patient had long suffered from gangrene and chronic arteritis, and in the presence of the physician all the manifestations of life gradually ceased and he was declared dead Twenty minutes later faint signs of respiration were detected, and the physician's stimulating measures restored him to life Death occurred finally forty days later In another case the attending physician had signed the death certificate, which was countersigned by the priest. The latter returned the next day to see the sick daughter of the deceased, and in passing through the room where the corpse lay on the bier he noticed unmistakable signs of life, and assisted in the woman's restoration The details of each of these twelve cases are given with names, addresses and dates In conclusion, Icard presents the provisions of the laws in France in regard to the certification of death They are very prudent and conservative, but are practically a dead letter, never being enforced according to the spirit of the regulations They provide for careful examination of the subject before the certificate of death is signed by the registered physician, and he must wait for cadaveric rigidity and putrefaction before he signs The legal interval of twenty four hours before burial is permitted should commence from the moment when the authorities are notified of the death, and not from the moment of supposed death Until the expiration of the twenty four hour interval the subject should be regarded as a sick person and not as a corpse, and treated as such The public authorities urge that every family should be instructed in the care to be given the subject until the complete expiration of the legal interval This interval may be shortened in certain cases on condition that the death has been certified with the greatest care, and that it is known to be real and not apparent Icard's study of the subject in other lands besides France shows him that death certificates are liable to be signed haphazard by physicians anywhere, sometimes without actual inspection of the supposed corpse He mentions one instance in which the certificate was signed blank and left with the mother of a sick child, for her to fill in the exact hour of death and forward to the authorities Icard has this blank certificate in his possession and regards it as a monument of inexcusable carelessness He cites Brouardel to the effect that 3 instances at least are known in which apparent death lasted a long time, but the supposed corpses were finally restored to life The subjects he mentions are the men hung at Boston and Perth, and Roger's case of revival after burial Apparent death is life under the external aspect of death Every dying person passes through this phase before death is finally complete

Semaine Médicale, Paris

50 (No 34) *Les formes cliniques du cancer de l estomac L Bard
51 Des troubles cardiaques tardifs consécutifs aux angines P Busquet. Abstract.
52 Hetérotopie thyroidienne E Tavel Abstract
53 Etude des abcès du foie chez l enfant (liver abscess in children) Covington Abstract

48 **Traumatic Chylothorax.**—Four of the 10 cases of traumatic chylothorax on record terminated fatally In 2 cases the effusion was spontaneously reabsorbed Others recovered after nine or ten punctures, and death in the fatal cases seems to have been due principally to the large amount of fluid—six or seven liters—found in the pleura, actually suffocating the patient Aspiration is not always successful, however one subject succumbing from inanition after the tenth puncture

Port has reported excellent results from thoracotomy in one case, and it is quite a question whether immediate thoracotomy is not the preferable procedure when the diagnosis of traumatic chylothorax is once definitely established.

49a **Localization of Motor Functions in Spine**—This was one of the subjects on the order of the day at the recent neurologic congress Addresses were presented by Sano of Antwerp, Grasset of Montpellier, and Parhon of Bucharest They emphasized the fact that much further study is needed on this subject, and also that the various theories proposed are all too exclusive

49b **The Criminal Insane**—After long discussion of this subject the congress adopted resolutions asking for the creation of special asylums for the particularly dangerous insane as an urgent necessity This would include the criminal insane

49c *Mode of Arresting Epileptic Seizure*—Crocq of Brussels has found that the clonic spasms can be suppressed and the consciousness restored by placing the epileptic on his left side during the tonic period. This method of arresting the seizure was first proposed by McConaghey of Edinburgh, and Crocq has found it successful in every instance in which he has applied it

49d **"Combined Plantar" Sign of Hysteria.**—The same author calls attention to the simultaneous abolition of the cortical plantar reflex or flexion reflex, and of the spinal plantar reflex or fascia lata reflex, which he calls the "combined plantar reflex" He regards its abolition as pathognomonic of hysteria

49e **Radium in Nerve Therapeutics.**—Foveau de Courmelles describes numerous experiences to show the great sedative power possessed by radium It soothes pain, whether organic or cancerous, nervous or neuralgic Some cases of facial neuralgia and one of sciatica, long rebellious to other measures, yielded to the action of the radium rays The girdle pains in 2 cases of ataxia were cured, one by the radium and the other by the Röntgen rays The subjects were not informed in regard to the nature of the treatment, so he thinks that suggestion may be excluded.

49f **Sodium Nitrite in Tabes.**—Oberthur has cured the pains in rebellious cases of tabes by sodium nitrite given by mouth or subcutaneously

50 **Clinical Forms of Cancer of the Stomach.**—Bard proposes tentatively a classification of gastric cancers which he thinks will aid physicians in prognosis and in their decisions, and will improve the results, both immediate and remote, of surgery He divides the 3 main groups, pyloric, extra pyloric and sub peritoneal cancers, into the subgroups of typical, abortive and latent The abortive forms are the most puzzling In the pyloric group it includes the annular, colloid cancer, inducing insufficiency of the pylorus instead of stenosis The latent form includes the submucous cylindroid cancer or Brinton's plastic linitis, which substitutes esophageal symptoms for the ordinary pyloric ones The abortive form of extra pyloric cancer includes the painful dyspeptic form (generally an ulcer cancer at some distance from the pylorus), and the cachectic form without gastric phenomena. The latent form of extra-pyloric cancer includes the variety simulating pernicious anemia, generally owing to frequent slight hemorrhages, and the variety inducing symptoms of stenosis The cancer in the latter case may be near the cardia, and the secondary stenosis may simulate cancer of the esophagus, or it may be gastro colonic, simulating cancer of the colon and terminating in a gastro colonic fistula It may, further, be the cancerous form of hour glass stomach, or it may be a gastrohepatic cancer th extensive perigastric adhesions, fixation of the liver and ent of the stomach from a longitudinal stricture, simu- a chronic subhepatic peritonitis The latent form may early and predominating symptoms in remote organs, in the liver, simulating primary cancer of the liver or osis, or it may assume a peritoneal form, simulating tuberculous peritonitis or portal cirrhosis The subperitoneal fo rare There is usually a palpable tumor, and the indicate peritonitis without apparent partici stomach Secondary cancers in the stomach generally occur in this locality He has observed several of this kind of thyroid, and some of ovarian origin He urges that the statistics of cancers operated on should be classified according to this or some similar plan By this means it would be possible to learn which forms are legitimate subjects for intervention, and which are best left alone He is convinced that operative results will be found particularly encouraging in certain cases of scirrhous annular pyloric cancers, in ulcer cancers, in the extra pyloric variety of the dyspeptic type and in plastic linitis, no matter how extensive He reviews in detail the indications for the various palliative and radical operations concluding with the remark that the latent gastro colonic variety of cancer might suggest benefit from an artificial anus, but this would entail only disappointment

66 *Important Roentgen Findings in Case of Shot in Eye. A Kohler—Schrotschuss ins Auge
67 Electro-diagnostische Untersuchungen mit Condensatoren Entladungen (examination with condenser discharges) L. Mann (Breslau) (Commenced in No 33)

55 *Polymyositis and Polyneuritis in Measles.*—Jessen describes in detail a case of measles diagnosed the sixth day The sixteenth day the symptoms indicated acute articular rheumatism, but these rheumatoid manifestations were evidently the first indications of a severe, acute polymyositis, which he attributes to the measles Edens describes a case of polyneuritis due to measles The illness began with stormy onset, soon complicated by bronchopneumonia, and later with otitis media, followed by the polyneuritis He knows of only one other case of polyneuritis due to measles on record

59 **Treatment of Stones in the Gall Bladder**—König reports the operative treatment of the milder forms of cholelithiasis requiring surgical intervention, as practiced at the Charité clinic He describes 7 cases to show the variety of operations devised to meet individual indications

60 **Hygiene of the Teeth**—As recent progress in dentistry Warnekros describes electrolysis to prepare a tooth for filling A current of from 1 or 2 milliamperes is passed through the tooth, wet with salt solution, for five minutes, a temporary filling is applied and the electrolysis repeated a few days later This sterilizes the tooth completely, ready for the filling The bactericidal action is due to the generation of nascent chlorin and oxygen at the positive pole He advises the alternate use of hard and soft tooth brushes, of varying shapes The use of a single brush or of a single shape causes certain parts of the teeth and gums to be unduly scrubbed and others neglected, with abrasions in some parts Energetic use of the teeth in chewing is the best mode of cleansing them He urges physicians to order their patients in prolonged illness to chew some indifferent substance, and in all cases to chew vigorously The spectacle of a neglected mouth, a hot bed for bacteria, which is so frequently observed in the sick, would become rarer He also advises physicians to order more solid food for children who still have their first dentition The best plan

for the development of the teeth would be to have weakly children always given hard, black bread, but as this is impracticable, hard slices of chocolate or the like might be used to advantage. This might hasten the decay of the milk teeth, but would aid in the strong development of the permanent teeth He observed in Egypt that the first dentition suffered from caries, but that the permanent teeth were much more perfect than among corresponding European children He attributes this soundness of the permanent teeth to the constant practice of sucking and chewing sugar cane It does not prevent the decay of the milk teeth, but insures stronger permanent teeth He pays a high tribute to American dentistry, remarking that America still leads the world in dentistry in the present as in the past. In conclusion, he urges the general adoption in hotels, depots and other public places and private houses of cuspidors fashioned on the principle of dentists' basins with a rinsing jet of water Prohibition of spitting in public places, and the uninviting aspect of the cuspidors now in use may lead to the swallowing of infectious saliva or sputa. Dentists will gladly co operate with surgeons and hygienists and others in this and similar questions, and their advice may frequently prove very valuable

62 **Further Experiences with the Scopolamin-Morphin Narcosis.**—Korff summarizes the results observed in 200 cases of this narcosis In the dosage he uses (see THE JOURNAL, xli, page 1568), it is free from danger to heart or lungs No disturbances on the part of kidneys, liver, digestive tract, etc, have ever been observed The general practitioner can employ it without a special anesthetist The action of the narcosis varies with different individuals Sometimes a further dose of 0002 3 gm. scopolamin and 005 to 01 gm morphin may be required, or chloroform or ether The chief advantages are the absence of the tendency to vomit during and after the operation. Also that fluids can be ingested immediately before the narcosis and directly afterward. The precaution must be observed not to allow the tongue to fall back and obstruct the breathing, especially in toothless subjects, during the profound sleep during and after the operation, the result of the narcosis. Drawing the lower jaw forward draws up the tongue and obviates this danger

63 **Talma on the Talma Operation.**—Three questions are discussed in this communication Does the collateral deviation of the blood induced by the operation affect cirrhosis of the liver favorably? Can the *omentopexy* reduce the danger of hemorrhage from the overfilled veins? and can the establishment of collateral circulation in case of portal thrombosis compensate the worst of the circulatory disturbances? Talma reports experiences which compel an affirmative answer to the first two questions In respect to the third question, he cites a case of pronounced phlebo sclerosis of the portal vein, the probable cause of the thrombosis observed It is the only case of which he has knowledge from which an opinion can be formulated in regard to the significance of omentopexy in case of occlusion of the portal vein in man. The patient was a man of 30, who had been subject for fourteen years to atrophic, annular cirrhosis of the liver, with ascites but no icterus, attacks of violent pain from fibrous splenitis and caput Medusæ. Omentopexy was performed, and for two months the patient was free from ascites The collateral vessels became much enlarged at the point of attachment and around the esophagus Then the ascites recurred from portal thrombosis, a consequence of old phlebo sclerosis and partial occlusion of the portal vein with an old organized thrombus In Umber's case the portal vein had been congenitally occluded, and likewise the splenic vein, but the collateral circulation had always been sufficient, and no disturbances had been noted The liver was sound The omentum was adherent to the liver, kidneys, spleen, intestines and abdominal wall, and there were numerous adhesions between the intestines, etc. The occlusion of the portal vein was a necropsy surprise, the collateral circulation having obviated all disturbances until fresh thrombosis occurred in the collateral circulation The conclusions which Talma draws from this and his own case are that it is a good plan to make the omentopexy multiple, that is, to fasten the omentum at several points Another case of recent thrombosis in an old phlebitis has recently been described in Holland, remarkable on account of the hyperemia of the abdominal wall and the development of wide veins at the points where the spleen and diaphragm had become adherent Stephan has also reported a case of acute thrombosis of the portal vein followed by fatal necrosis of a large part of the intestines Comparing the findings in this case with those in the case of long established occlusion of the portal vein, shows better than any words the importance of collateral side routes circulation for the blood in case of liver cirrhosis

66 **Radiogram of a Shot in the Eye**—Köhler obtained a good radiogram of the shot, but when the subject looked upward the rays cast shadows of two pieces of shot, when in fact there was only one. This confirmed the assumption that it was located in the eyeball

68 **Trauma in Etiology of Aortic Insufficiency**—Sinnhuber thinks that far too little attention has been paid hitherto to trauma as a factor in the production of valvular affections The text books suggest it only as a bare possibility, and very few instances have been published, among them Hektoen's case (1892) of rupture of the aortic valves During the last year and a half Sinnhuber has had occasion to observe 3 cases at the Berlin Charité in which the symptoms of aortic insufficiency were traceable to a contusion or fall on the chest Two of the patients applied for relief without referring to any traumatism in their antecedents, and it was only learned by direct questioning The particulars are detailed, and also the post mortem findings in a fourth case The latter was diagnosed as traumatic aortic insufficiency, but the necropsy revealed merely a chronic, recurring endocarditis The patient was a man of 38, previously healthy, whose business was the moving of safes With 8 other men he had carried a very heavy safe up a flight of stairs, then walked a mile home and slept for several hours When he awoke he experienced progressive dyspnea, and the next day much pain in the abdomen and in the region of the stomach, and vomited all that he ingested, the vomitus was blood streaked. The dyspnea became so excessive that he entered the hospital the tenth day Traumatic aortic insufficiency was diagnosed, but the necropsy revealed merely chronic, recurring endocarditis Notwithstanding these negative findings in this case, Sinnhuber thinks there can be no mistake in the diagnosis of the 3 other cases One man had been devoted to athletics and had been found perfectly sound when examined eleven months before the accident, while four weeks after, a severe heart defect was discovered He presented the symptoms of severe aortic insufficiency, with hypertrophied left ventricle, and other symptoms visible even from a distance. The second patient was a cabinet maker of 42, who had worked steadily until the accident Two months afterward he was unable to work at all on account of symptoms

secretion of pancreatic juice and possibly also of the bile The conclusions are all favorable to the administration of hydrochloric acid, both transiently and continuously, in addition to dietetic measures, in all cases of hypochylia or achylia gastrica when the appetite is depressed, and there are fermentations in the stomach, with diarrhea The digestive power was wonderfully increased, in many cases by giving from 100 to 300 c c of a one tenth normal hydrochloric acid solution When pepsin was added it was in the proportion of 5 gm to 100 c c of the same. Some of the patients drank the solution through a glass tube, others had it introduced through a stomach tube None complained of the taste

87 **Physiologic Study of Natural Gastric Juice (Pigs)** — Erb argues that the gastric juice derived from pigs by a Pawlow fistula can never be a physiologic secretion The operative intervention renders it always more or less pathologic

88 **Pressure in the Right Auricle in Valvular Defects.**— Horner has been giving the Gaertner test a thorough trial on healthy subjects and on those with valvular defects It was described in these columns, page 687 of vol xlii The arm is lifted slowly and passively, and the point at which the veins collapse is marked by comparison with the standards Gaertner has established Horner's tests confirm the great value of this new technic, with certain restrictions He reports a number of cases of mitral incompetency, etc, to show the characteristic findings in various valvular defects

92 **Role of Hyperemia and Age in Origin of Tumors**—Rössle proposes a theory to account for the origin of tumors by variations in the cells of the organism caused by age and congestion Histologic and physiologic study of old age is the most promising line for research on the origin of malignant cancer

95 **Sublimate in Puerperal Infection.**—Fabio describes a case of severe puerperal infection, apparently in the last stages when first seen He injected intravenously 3 mg of a 1 per thousand solution of sublimate, with local measures The temperature declined a little the same evening and there was slight abatement of the symptoms Six intravenous injections were thus made in the course of a week, after which the patient was soon restored to health, an extensive ulceration of a laceration of the vagina having healed completely [Bidoli has recently published a similar case of recovery under sublimate as a last resource (*Policlinico*, July 9) The patient was apparently moribund —ED]

96 **Digitalis in Croupous Pneumonia**—The patient had previously passed through four attacks of croupous pneumonia between the ages of 16 and 33 They had been treated by the ordinary measures, with the usual protracted course At 34 another attack occurred and 3 and 4 gm of digitalis leaves were infused and administered on following days The disease was arrested and recovery rapidly ensued, in marked contrast to the preceding attacks, and notwithstanding the fact that the onset had been stormy Digitalis evidently has different effects on a healthy and a pneumonia subject It may have some specific bactericidal action on the causal germ, or the intense leucocytosis induced may have the same result, or the leucocytes may be rendered more resistant Carbone insists that pneumococcus infection is due to an intoxication of the system by absorption of the products of the elements of the blood, destroyed by the pneumococci If this be true, then treatment with digitalis, to enhance the resisting power of the leucocytes, is the logical indication, and experience is crowning it with success

98 **Sero-Diagnosis of Primary Tuberculosis of the Middle Ear**—De Simoni cites 3 cases to show how valuable the agglutination test may prove long before other signs are available. He tabulates the findings in 14 other cases in which the test was negative, and the course of the affection confirmed its non tuberculous character

102 **Palpation of the Heart Outlines**—Bassi urges that greater reliance should be placed on the palpation findings in the diagnosis of heart disease He has found palpation a particularly valuable means of controlling percussion findings The heart action in children is so vigorous that palpation gives very significant results in their case He adds two diagrams to illustrate the findings in severe cases of organic mitral defect The heart area determined by palpation coincides with the area of relative dullness in case of long established mitral defects, while it coincides with the area of absolute dullness in recent cases The heart can not be outlined by palpation in non febrile adults free from heart affections.

PLEURAL EFFUSION IN HEART DISEASE *

J DUTTON STEELE, M D

Associate in Medicine University of Pennsylvania Bacteriologist to the Presbyterian Hospital

(From the Department of Clinical Medicine University of Pennsylvania.)

PHILADELPHIA

In a paper entitled "The Distribution and Etiology of Cardiac Hydrothorax," which was published in 189[illegible], I called attention to the fact that passive pleural effusion may occur in the course of failing compensation of the heart, before there is any tendency to external dropsy, and that this pleural effusion is very often unilateral, with a preference for the right side That paper contained an analysis of the autopsies of 75 cases of hydrothorax occurring in patients with undoubted disease of the heart muscle It was shown that in three-fourths of these cases the effusion was greater on one side than on the other, and in one-fifth the effusion was unilateral The greater amount of fluid was on the right side in three-fourths of the unequal effusions and in 10 of the 13 cases of the unilateral effusions the fluid was found in the right pleural sac

The material for my table was obtained from the notes of 2,427 autopsies contained in the records of the Philadelphia Hospital, and of the Middlesex Hospital in London I also published the clinical notes of 4 cases from the wards of Dr Stengel and Dr Packard that showed this right-sided hydrothorax In all of these cases the formation of the effusion preceded the edema, and I called attention to the fact that such effusions may precede external edema

Dr Stengel (University of Pennsylvania Medical Bulletin, 1901), took up the subject in a paper published in 1901, and gave an analysis of seventeen instances of hydrothorax which occurred in 100 consecutive cases of cardiac disease His conclusions are probably of more value than those of my first paper, although mine were obtained from the autopsies of many more cases, because Stengel's analysis was based on clinical notes of living patients, while mine were all fatal cases, for it will be readily understood that in autopsy findings the sequence of events of the morbid state can not be accurately determined Consequently it was impossible to tell from autopsy notes whether in double effusion the fluid had been unilateral at the onset or not, and it was usually quite impossible to tell whether or not the pleural effusion had preceded general edema and effusions into other serum cavities

In the 17 cases of hydrothorax that Stengel gives, the effusion was confined to the right side at some time in the course of the disease in 7 cases, 7 more were bilateral, with greater involvement of the right side, and in 3 cases the effusion was entirely left sided In 8 of Stengel's 17 cases edema was absent or slight

The literature of the subject has been fully considered in the papers by Dr Stengel and myself It is sufficient to say that several writers of text-books, including Pepper, Osler, Baccelli, and Rosenbach, state that cardiac hydrothorax is apt to occur before general edema, and is then unilateral with preference to the right side Many observers have reported isolated cases of right-sided cardiac hydrothorax, and a group of Italians, including Piazza-Martini, Villani, Lizzato Cardenelli and Peter, have called attention to the occasional occurrence of right-sided pleural effusion of a non-inflammatory nature in atrophic cirrhosis of the liver But so far as can be determined there has been no attempt made to consider the distribution or etiology of cardiac hydrothorax by an analysis of a series of cases before the subject was taken up by Dr Stengel and myself [1]

In endeavoring to obtain another series of observations on the distribution and etiology of the hydrothorax of cardiac disease, I have gone over the records of the Presbyterian Hospital in Philadelphia since 1895 In this period of nine years there have been 31 cases of hydrothorax in patients with well-marked disease of the heart muscle and enlargement of that organ Fortunately, 4 of these cases have been under my personal observation during the past winter in the wards of the Presbyterian Hospital in the service of Dr John H Musser, and I had the opportunity of examining two of these postmortem

The condition required in selecting these cases and in deciding between cases of cardiac effusion and effusion from other causes was that there should be decided evidence of myocardial disease and enlargement of the heart It was required also that the cardiac condition should be predominant, or at least a very prominent factor in the patient's condition Aneurism, tumor or any other cause for effusions was sufficient to throw out the case in question

With one or two exceptions the patients were free from fever, pain and cough The exceptions were one case of acute pleurisy occurring in a case of well-marked disease of the heart, and two cases of acute endocarditis with great cardiac enlargement and with much effusion

---

*Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Practice of Medicine and approved for publication by the Executive Committee Drs J M Anders, Frank Jones and W S Thayer

[1] Beside Dr Stengel's paper the following communications concerning pleural effusion of heart disease have appeared in current medical literature since 1897 Gerhardt Pleural Effusion in heart disease Rosenbach Localized Congestions and Effusions in Cardiac Disease Münchener med. Woch No 14 1901 Germani Right sided Hydrothorax in Cardiac Disease Gazz. degli Ospedali, No 99 1900 Barie The Involvement of the Pleura in Heart Disease Semaine Médicale, 1902, No 4. Esser Pleural Effusion in Heart Disease Münchener med. Woch. No 4 1902

As has been said, every case presented distinct signs of degeneration of the myocardium with enlargement of the heart, hypertrophy and dilatation

Most of the cases had valvular lesions, with or without arterial changes, some had arteriosclerosis and nephritis, and there were two instances of acute endocarditis and cardiac dilatation in children.

In some cases all the chambers of the heart were dilated, in some all the chambers were enlarged, but the right side was mentioned as particularly affected In others the left side was the only part of the heart enlarged or was the part particularly affected

In 3 cases one or the other of the pleural sacs was totally obliterated by adhesions, and these have not been included in the tables As I have said, in one case the effusion is apparently due to acute pleurisy, and occurred entirely on the right side This gives a total of 27 cases for analysis

The effusion was at some time during the period of observation confined to the right side in 11 cases, or 40 per cent The effusion was bilateral, but greater on the right side in 4 cases, or 15 per cent It was left sided in 5 cases, or 19 per cent, and double, but greater on the left in 6, or 22 per cent The effusion was double and equal in one case, or 3 per cent, right sided in 60 per cent, left sided in 40 per cent

The figures in my first paper based on autopsy findings alone are

Right-sided hydrothorax, unilateral or greater on the right side, 41 cases, or 77 per cent, left-sided hydrothorax, unilateral or greater on the left side, 12 cases, or 23 per cent

Stengel's 17 cases of hydrothorax were practically all right sided, since 2 of the 3 left-sided effusions could be explained by the obliteration of the right sac by adhesions, and the other case was probably due to aneurism Consequently the figures in the analysis of the Presbyterian Hospital cases are not so conclusive that cardiac hydrothorax in the great majority of cases is right sided as those of Stengel or of my previous article

The Presbyterian Hospital figures, however, show that the effusion has a decided preference for the right side The figures indicate very decidedly that the pleural effusions of cardiac origin are usually unilateral or unequal Moreover, when the etiology of such effusions is considered, it will be seen that the larger percentage of left-sided effusion in the Presbyterian Hospital figures, when taken in connection with the side of the heart affected, is very suggestive and interesting

The effusion was entirely left sided at some time in 5 cases, or 10 per cent, and was double but greater on the left side in 5 more cases

That is, the effusion showed a preference for the left side in 10 cases or 40 per cent in round numbers, as contrasted with 15 cases, or 60 per cent that were right sided

The effusion was double and equal in but one instance, showing very decidedly that these pleural effusions in heart disease are unequal in a great majority of cases

A very interesting point shown in the table is that, while right-sided effusions occur with enlargement of the right heart, left-sided effusions are usually associated with enlargement of the left heart This phase of the subject will be considered more in detail in the section on etiology

It was difficult to ascertain whether the formation of the effusion preceded external edema Such cases are usually not admitted to the hospital until the severity of the symptoms are such that external edema is present to a considerable degree It is then usually impossible to fix the time at which the effusion commenced from the history of the patient

In 3 of my cases edema was absent or slight on admission, while there was considerable effusion, in 3 other cases the edema disappeared before the effusion

This small number of cases, however, together with the clinical reports in my first paper, and by the observation of Stengel, Gerhardt and others, demonstrate that such effusions may precede external edema

Various theories have been advanced to explain the formation of this unilateral or unequal pleural effusion in heart disease

Wintrich, in an article extensively quoted in my first paper, gave obliteration by adhesions of one of the pleural sacs as the most frequent cause for unilateral hydrothorax He says, however, that the effusions may rarely be one sided, when both pleura are free

Bucquoy, Saint Phillipe and Dequet insisted that the effusion was inflammatory and attributed it to pulmonary infarction on the right side Their theory, however is not supported by the researches of Gerhardt and Stengel, or by either of my lists of cases

Esser, in a recent paper, reported 3 cases of unilateral right-sided effusion without symptoms in patients with cardiac dilatation, in which autopsies showed large bronchial glands in the root of the right lung He attributed the effusion to the interference with the lymphatic circulation of the right pleura, which was produced by these glands This effusion occurred in heart disease, because in such cases the general circulation is feeble, and consequently there is a greater tendency to lymphatic stasis The improbability of this explanation is obvious Such a condition was not noted in any of the cases cited by any of the other authorities Unilateral enlargement of the bronchial lymph glands is not a common enough condition to explain a phenomenon of such regularity as the occurrence of these effusions

As is shown in Stengel's paper, right-sided effusions in dilatation of the heart are not caused by obstruction to the general lymphatic circulation produced by interference with the circulation of the superior vena cava, and hence with that of the right lymphatic duct The right lymphatic duct is protected by valves and if general lymphatic obstruction was the cause of the effusion, unilateral swelling of the arms, neck and chest would necessarily be more frequent

A group of clinicians, mostly Italians, have observed right-sided hydrothorax in cirrhosis of the liver Villani reports nine such cases of atrophic cirrhosis, with right-sided pleural effusion in two, of which the diagnosis was confirmed by autopsy He explained the effusion by assuming that in such cases inflammation of the capsule of the liver extending through the diaphragm caused a low grade of inflammation in the right pleura with effusion without symptoms He extended this theory to right-sided hydrothorax in cardiac disease He argued that in such cases of heart disease the liver is distended by passive congestion, and its capsule is subacutely inflamed This inflammation spreads through the diaphragm in the same manner as he assumed it would in cirrhosis of the liver Peter and Huchard held approximately the same view

Piazzi-Martini reported several cases of right unilateral hydrothorax in atrophic cirrhosis and explained the condition by assuming that the dilated veins of the esophageal plexus pressed on the vena azygos and interfered with the return of blood from the right pleura

The liver was noted as distinctly enlarged in four of the Presbyterian Hospital cases, and in six of Stengel s seventeen cases Four of the Presbyterian Hospital and three of Stengel's cases had ascites All of these cases, however, showed much general edema, so that the abdominal effusion may have been merely part of the general anasarca

The responsibility of the inflammation of the liver capsule in the cases of right-sided effusion is not obvious, and this theory fails entirely to account for the effusion that is confined to the left side, or greater on that side

The theory that appears to explain most satisfactorily the preference of these pleural effusions for the right side, supposes that enlargement of the right heart and especially of the right auricle can press on the root of the right lung and obstruct the vena azygos major

The vena azygos major represents the common trunk of the nine or ten right lower intercostal veins. It lies on the right side of the bodies of the dorsal vertebræ extending from the diaphragm as high as the third intercostal space From that point it arches forward and curves around the root of the right lung and then empties into the superior vena cava just before that vessel enters the pericardium It receives as tributary the right superior intercostal vein, which is the common trunk of the three upper intercostal veins The vena azygos major consequently drains the whole of the costal layer of the pleura from the right side Obstruction of this vein would, therefore, result in congestion and stasis in the whole of the right pleural sac

The vena azygos major also receives as tributary the vena azygos minor which is the common trunk of the lower four or five intercostal veins on the left side It crosses over the body of the eighth dorsal vertebra to join the vena azygos major Obstruction of the vena major would consequently cause congestion in the lower third of the left pleural sac

The vena azygos major, as it curves around and partially surrounds the root of the right lung, is in a position which renders it especially liable to compression As has been said, such obstruction would produce stasis and congestion in the whole of the right pleura and in the lower portion of the left pleura and consequently the resulting effusion in its early stage would be wholly right sided, and in its later stage bilateral but greater on the right.

In my former article I advanced the theory that right-sided pleural effusions in heart disease were produced by pressure exerted on the root of the right lung by a dilated right auricle It has been shown how such pressure would tend to compress the vena azygos major, and hence could cause a passive effusion on the right side, and in case the pressure was long continued would produce a smaller effusion in the left sac

Dilatation of the right auricle was especially mentioned in sixteen of the thirty-five cases of right unequal hydrothorax tabulated in my first paper The figures given by the analysis of the Presbyterian Hospital cases strongly support this theory

In sixteen cases of right unequal hydrothorax in the Presbyterian Hospital list the right side of the heart was much dilated in fourteen Both sides were dilated in six cases and the left side alone in two That is the right side of the heart was greatly dilated in nine-tenths of the sixteen cases

The two autopsies which I had the opportunity of making personally on two of the cases in the Presbyterian Hospital list, showed much dilatation of the right auricle and ventricle In both the right auricle pressed on the root of the right lung, and in both the vena azygos major was engorged and dilated There were no adhesions or enlarged bronchial glands or great congestion of the liver which would suggest any theory for the production of the effusion other than that of pressure on the azygos vein

The report of these two cases in detail, together with the notes on the autopsies, are as follows

Case 19—J G, male, white, aged 50 years

Clinical Diagnosis—Myocarditis, mitral stenosis and insufficiency Large right sided pleural effusion which had been tapped once. Specific gravity of fluid 1015, with 4 grams of albumin per liter

Pathologic Diagnosis—Double pleural effusion greater on the right side Mitral stenosis Thickening of the coronary arteries and myocardial degeneration Great dilation of the right auricle The right auricle pressed directly on the root of the right lung The vena azygos major was dilated and engorged

History—The patient had always been a drinking man, but beyond this little concerning his personal or previous history could be obtained About two years previously he began to suffer from morning vomiting and gradually became short of breath on exertion and lost his usual vigor He had been under a physician's care for the two months previous for dyspnea and edema of the feet

Examination—On admission he had much general edema and some ascites There were signs of pleural effusion on the right side below the level of the fourth rib The left side was free The day after admission 2,000 c c of clear fluid was drawn from his right pleura The specific gravity of the fluid was 1015, and it contained 4 grams of albumin per 1,000 parts, and contained a small amount of blood After the fluid was withdrawn the left border of the heart was found to extend to the anterior axillary line, the upper border was at the second rib, and the right border was at the right border of the sternum There was a murmur of mitral insufficiency at the apex preceded by short, rough presystolic murmurs, apparently due to mitral stenosis There was also a rough systolic murmur in the aortic area transmitted to the carotid There were no other murmurs The action of the heart was weak and irregular The pulse was small and weak, and there was moderate thickening of the radial and temporal arteries The liver was slightly enlarged, but did not pulsate There was no pulsation in the veins of the neck.

Course—The patient was slightly delirious for the next few days His pulse grew very rapid and irregular and he died suddenly six days after admission

Autopsy—Both pleuræ were free from adhesions There was 1,500 c c. of clear, slightly blood stained fluid in the right pleural cavity The right lung was slightly compressed and somewhat congested, but otherwise normal. There were 200 c c of fluid in the left pleura The left lung was congested

The left border of the heart extended as far to the left as the anterior axillary line, and the right border, which was formed by the right auricle, extended 4 cm to the right of the sternum from the third rib to the fifth interspace All the chambers of the heart were distended. The left ventricle and left auricle were much dilated, and also much hypertrophied The right ventricle was dilated and hypertrophied The right auricle was tremendously dilated and as large as a boy's fist. The heart muscle was very pliable and yellow, and evidently much degenerated The coronary arteries were hard, stiff and calcareous and their caliber was diminished There was much thickening of the mitral leaflets, and the leaflets themselves were adherent, forming a typical funnel shaped valve, such as is often seen in mitral stenosis The aortic valves were thickened and rough, but were competent. The tricuspid orifice was dilated and admitted four fingers so that there was probably some insufficiency of the tricuspid valves as well The portion of the heart formed of the right auricle pressed directly on

SUMMARY OF CASES OF PLEURAL EFFUSION IN HEART DISEASE

Number	Age in Yrs	Sex	Condition of Pleural Sacs	Pleural Adhesion	Diagnosis	Cardiac Enlargement	External Edema	Liver	Remarks
1	37	M	Effusion commenced on left side Autopsy both pleuræ half full		Autopsy Mitral stenosis and insufficiency, aortic regurgitation, tricuspid insufficiency	Both sides enlarged	Effusion preceded edema		
2	53	M	Autopsy Right pleura 200 c c Left pleura Free		Mit l stenosis and insufficiency	All chambers enlarged, especially left ventricle weight 625 grms	None		
3	56	M	Autopsy Right pleura 270 c c Left pleura Free		Mitral insufficiency	All cavities much distended, especially right auricle, weight 450 grms			
4	42	M	Right sided effusion before fourth rib, which increased rapidly, tapped once, 1200 c c, left side remained free		Mitral insufficiency tricuspid insufficiency	Enlarged to left and right	Present	Enlarged and pulsating	Clear yellow fluid, pulsation in jugular vein and liver
5	36	M	On admission Double effusion, the left effusion disappeared first, confirmed by puncture one week after admission, right-sided effusion to first rib, left side free		Mit l stenosis and insufficiency	Enlarged to left and right	Present on admission	Enlarged and pulsating	Fluid clear yellow
6	52	M	Right-sided effusion to third rib, left side free		Mitral and tricuspid regurgitation	Enlarged to left	Present on admission ascites		
7	33	F	Left sided effusion below fourth rib, right-sided effusion below sixth rib, confirmed by autopsy		Autopsy Mitral and tricuspid, stenosis and insufficiency	All cavities dilated, especially right auricle	Present on admission	Congested	
8	52	F	Clinically and at autopsy, large double effusion		Mit l stenosis and insufficiency tricuspid insufficiency	Bulk of heart made up of greatly dilated auricles, the right auricle was especially dilated	Present on admission	Congested	
9	52	M	Lower half of right pleura contained one quart of fluid at autopsy	Both sides obliterated, except lower half of right pleura	Arteriosclerosis, fatty heart	Both sides enlarged and dilated			Pulsation in jugular vein
10	43	F	Autopsy Lower half of right pleural sac contained 8 ozs of fluid	Both sides obliterated, except lower part of right pleura	*Fatty heart*	*All chambers dilated especially right side*			
11	68	M	Clinically Right-sided effusion, left free Confirmed by autopsy	None	Autopsy Fatty heart atheroma, mitral stenosis, aortic thickening	All chambers enlarged, especially the right and left auricles, weight 650 grms	Present		
12	40	F	On admission Left side, effusion up to third rib, right side, effusion to fifth rib, three weeks later, double effusion, tapped once Soon after patient developed fever with development of pus in left pleura and 1600 c c pus was removed		Mitral insufficiency and stenosis, action weak and irregular	Enlarged to left and upward in left			
13	74	F	Clinically on admission Acute pleurisy on right side with effusion up to the fourth rib no effusion in left side The effusion persisted for some days after subsidence of fever and then disappeared		Mitral insufficiency aortic insufficiency and roughening, fatty heart	Enlarged to left			Fever on admission which lasted for six days, with pain on right and cough, fever gradually disappeared
14	41	F	Clinically on admission Right-sided effusion up to angle of scapula, confirmed by autopsy	Autopsy Left side totally obliterated by adhesion	Autopsy Mitral stenosis and insufficiency, fatty heart, arterial sclerosis	Clinically enlarged, especially toward right	Present on admission		History of acute articular rheumatism, 3 weeks of sharp pain in chest, leucocytes 28,900
15	45	M	Clinically on admission Double effusion slightly greater on right, which gradually disappeared		Mitral stenosis and insufficiency, aortic insufficiency	Enlarged to left and right, left border, anterior axillary line, right border, right parasternal line	Present on admission, ascites which gradually disappeared as improvement occurred		Considerably jaundiced gradually improved until an attack of cerebral apoplexy caused death
16	52	M	On admission Right-sided effusion to third rib, confirmed by puncture, later some left-sided effusion.		Aortic roughening and regurgitation	Clinically, enlarged to right (right parasternal line) and to the left	Slight on admission	Enlarged to within 1 inch of umbilicus	Recovered slowly and effusion disappeared
17	40	F	Clinically Double effusion greater on left, confirmed by puncture Tapped left twice 310c c Tap'd right once 500c c		Clinically and at autopsy Mitral stenosis and insufficiency, tricuspid insufficiency, fatty heart, atheroma of coronary arteries	Autopsy Dilation of all chambers, but especially of the right auricle weight 600 grms	Present on admission ascites		Fluid 1020, albumin, 45 per 1000 Patient had been in hospital several times for same trouble, gradually grew worse and died, autopsy reported in full in paper
18		M	Admitted twice with pleural effusion Always on right, left side remained free right side tapped once 1200 c c and filled again rapidly and then disappeared as patient recovered but persisted longer than external edema		Mitral insufficiency, aortic insufficiency degeneration of myocardium	Enlarged to left and right	Present on each admission as cites, edema disappeared before the effusion		Had been admitted 4 times for cardiac disease, twice with pleural effusion, fluid 1014, albumin 15 per cent by weight, death no autopsy

SUMMARY OF CASES OF PLEURAL EFFUSION IN HEART DISEASE.—CONCLUDED

Number	Age in Yrs	Sex	Condition of Pleural Sacs.	Pleural Adhesion	Diagnosis	Cardiac Enlargement	External Edema	Liver	Remark
19	50	M	Clinically on admission Right-sided effusion up to fourth rib, left side free, right side tapped 2000 c c Autopsy Right side, 1500 c c , left side, 300 c c		Autopsy Fatty heart, atheroma of coronaries mitral insufficiency (relative?)	Clinically Left side enormously dilated, left anterior axillary line right border right edge Autopsy All chambers distended right auricle enormously dilated	Present on admission ascites	Congested and enlarged	Fluid 1015 albumin 4 per 1000, autopsy reported elsewhere
20	53	M	Autopsy Left pleura 1300 c.c. Right plura 730 c c		Autopsy Acute pericarditis chronic interstitial nephritis arteriosclerosis no valve lesions	Autopsy Enormous involvment of left ventricle	Considerable edema some ascites		
21	44	M	Left-sided effusion 750 c c at autopsy	Some on left side	Chronic parenchymatous nephritis, no valvular lesions fatty heart	Much enlargement of left ventricle	Present legs and eyes	Much congested	
22	60	M	Left-sided effusion	Some in right side	Aortic thickening fatty heart	Dilated hypertrophy of left ventricle	Both legs		
23	31	F	Autopsy Left pleura ⅔ full right pleura almost empty	None	Chronic interstitial nephritis no valvular lesions	Hypertrophy of left ventricle heart weighed 535 grms	Legs and eyes preceded pleural effusion ascites	Atrophic wgt 1420 grms	
24	57	F	Double effusion greater upon the left	None	Chronic interstitial nephritis no valvular lesion	Much hypertrophy of left ventricle weight 710 grms	Legs and face preceded pleural effusion some ascites	Congested and enlarged	
25	29	M	Autopsy Right sac contained 1000 c c	Left sac obliterated	Mitral stenosis and insufficiency general atheroma	All cavities enlarged, especially left venticle	Present on admission		
26	38	F	Autopsy Right pleura contained 400 c c left pleura contained 200 c c		Mitral tricuspid and aortic valves all thickened fatty heart	All chambers enlarged			
27	8	F	Autopsy Double effusion, greater on right		Mitral stenosis and insufficiency	Much enlarged especially right auricle and ventricle which were greatly dilated weight 690 grms	Present		
28	39	F	Autopsy Left pleura completely filled right pleura one-half full		Double aortic disease	Right side enormously dilated, left ventricle enlarged and made up bulk of heart	Legs some ascites		
29	33	M	Right effusion to 2nd rib which slowly increased left remained free.		Aortic roughening and insufficiency, mitral insufficiency	All chambers enlarged	Present on admission		
30	8	F	Double effusion decidedly greater on right confirmed by puncture right to 5th dorsal vertebra left to 8th dorsal vertebra		Acute endocarditis of mitral and aortic valves old mitral insufficiency and stenosis presystolic thrill at apex	Enlarged upward to 2nd rib and to right to right parasternal line enlarged slightly to left, probable dilation of left auricle and right side of heart	Slight of legs, disappeared before effusion		History of rheumatism and chorea improved and effusion disappeared, the patient had an irregular fever for the first 2 weeks after admission
31	12	M	Left-sided effusion up to angle of scapula disappearing as heart grew stronger and reappearing with relapse of endocarditis		Acute endocarditis myocarditis and pericarditis mitral insufficiency tricuspid insufficiency friction râles in pericardium on first admission	Enormous dilation of left ventricle and left auricle less degree of dilation in left side	Present on both admissions, disappearing rapidly		Sudden onset of acute endocarditis with fever first week leucocytosis, gradual improvement and discharge returned in 8 days with fever and return of all symptoms, systolic pulsation in veins of neck

the root of the right lung and must have exerted some pressure on it

The course of the vena azygos major could not be traced around the root of the lung since all the tissues were very edematous but the vein was dissected out as it ran up along the spine underneath the costal pleura It was distended by dark blood and was fully one-third of an inch in diameter The lower intercostal veins were correspondingly dilated The left azygos, or azygos minor, was small and collapsed, and could not easily be found The surface of the pleura showed nothing out of the ordinary

There was some ascites The liver was rough and hard, and here was a high grade of the cyanotic induration There was no perihepatitis The kidneys also showed cyanotic induration and were much congested There was no enlargement of the esophageal veins.

CASE 17 —A. B , female, colored, aged 40 years The patient had been admitted twice in six months for the same condition

Clinical Diagnosis —Much pleural effusion greater on the left side Myocardial degeneration and mitral disease Tapped twice Specific gravity of the fluid was 1020, and it contained 4 5 grams of albumin per liter

Pathologic Diagnosis —Double pleural effusion, greater on the left Fatty heart. Great dilatation of all the chambers of the heart, equally as great on the left as on the right side The vena azygos major was dilated and engorged

History —She had had several attacks of acute articular rheumatism In December, 1902, she began to suffer from dyspnea, vertigo, cough and fainting attacks In June, 1903 her feet began to swell for the first time. She was admitted to the hospital July 27

Examination —On admission she had much dyspnea and could not lie flat in bed There was no fever or cough Examination of her lungs showed evidence of effusion in both pleural sacs, but more on the left than on the right side The heart was enlarged to the left and to the right, the apex was in the sixth interspace one inch outside the mid clavicular line There were blowing systolic murmurs at the apex and in the aortic area The urine was of good specific gravity, averaging 1020 At first it contained albumin, but this disappeared as the patient improved

Course —She grew rapidly better under digitalis strychnin, nitroglycerin and rest in bed and was discharged in a few weeks At the time of her first discharge there was no evidence of fluid in her pleural cavity The patient remained fairly well until Nov 12, 1903, when she was again admitted with symptoms of failing compensation

Examination —At that time her condition was as follows

Thorax Evidence of effusion in both pleural sacs, greater on the left side The effusion extended to the level of the fifth rib on the left, and on the right to the level of the seventh rib Exploratory puncture gave clear yellow fluid on both sides This fluid had specific gravity of 1020 and contained 4 5 per 1,000 albumin Respiratory murmur above the effusion was clear with the exception of a few râles

Heart The heart was enlarged to the left, to the right and upward There was a systolic murmur at the apex, which was also heard in the aortic area, but was not transmitted to the vessels of the neck There was a distinct systolic murmur in the tricuspid area of a different character than that heard at the apex This murmur apparently originated at the tricuspid valve There was systolic pulsation in the veins of the neck

Liver The liver was somewhat enlarged but did not pulsate There was some edema of the legs and ascites

November 14 600 c cm of clear yellow fluid was drawn from the left pleura and November 17, 450 c cm were drawn from the left side November 18, the right chest was tapped and 500 c cm of clear yellow fluid was obtained

Blood Red cells 72 per cent, hemoglobin 68 per cent white cells 6,000 There was slight cough and no fever The urine was scanty and albuminous and contained casts The patient died suddenly December 3

Autopsy—The right pleural cavity showed some firm adhesions posteriorly probably diminishing the capacity of the right pleural cavity to a considerable extent The right pleural cavity contained 130 c cm of clear fluid, the left pleural cavity was free and contained 400 c cm of clear fluid The layers of the pleura on both sides were thickened but not congested The vena azygos major could be plainly seen lying against the spinal column on the right side It was considerably dilated and was approximately the size of a large goose quill The vena azygos minor was not dilated and was collapsed so that it could not be satisfactorily studied There was dilatation of the right and left auricle, about equal in degree The right auricle extended two inches to the right of the sternum in the fourth interspace There was dilatation and hypertrophy of the left ventricle and dilatation of the right ventricle The mitral valves were insufficient, due to the thickening of the valve leaflets and chordæ The tricuspid valves were insufficient, due to a dilatation of the valve orifice There was atheroma of the aortic valves and the aorta, and great thickening and calcareous infiltration of the coronary arteries The lumen of these vessels was considerably diminished The wall of the left ventricle near the apex was very thin The section of the heart muscles in these areas showed much degeneration There was hypostatic congestion of both lungs There was moderate fatty degeneration and fibroid changes in both kidneys The kidneys each weighed 160 grams The heart weighed 600 grams

In my first paper I reported the result of the autopsy on a case of double hydrothorax greater on the right side, increasing as the heart lost strength There was little ascites and edema, but the thoracic effusion preceded the appearance of the subcutaneous edema

Autopsy showed chronic fibrous myocarditis and hypertrophy and dilatation of the heart, especially affecting the right auricle The dilated right auricle pressed directly on the root of the right lung

The right pleural sac contained 1,600 c c of clear blood-stained fluid The visceral layer of the pleura was somewhat thickened, but there was no sign of acute inflammation The left pleural sac contained 600 c c of clear blood-stained fluid

The liver was slightly smaller than normal, and there were a few adhesions between it and the diaphragm which were evidently due to an old perihepatitis, but there was no evidence of any recent inflammatory process The bronchial glands were not enlarged nor diseased

Wintrich has reported a case of unilateral right-sided hydrothorax without external edema Wintrich remarked that no cause could be found for the effusion except a dilated right auricle, the result of chronic myocarditis from alcoholism There was no inflammatory change about the liver, nor ascites

Stengel reports two autopsies in his list, in which there was dilatation of the right ventricles, auricles and venæ cavæ, and marked backward pressure on the root of the right lung and azygos vein One of these was a case of unilateral right-sided hydrothorax, and the other was one of double hydrothorax greater on the right side

Dr Stengel states as his opinion that such pressure on the root of the right lung, causing compression of the vena azygos major, is the cause of the right-sided effusions observed in his cases In his article he gives a very convincing anatomic diagram prepared by Dr G G Davis, which shows very plainly how dilatation of the right side of the heart may press on the root of the right lung, and compress the vena azygos major

Dr Stengel and myself can not claim the entire credit of originating this explanation for such right-sided effusions Baccelli advanced this theory in a modified form as early as 1863 He assumed that a dilated right heart produced obstruction of the vena azygos major not by direct pressure on the root of the lung, but by a downward displacement of the right side of the heart due to its increased size and gravity The superior vena cava would then be carried downward and with it the azygos major, consequently this vein from its anatomic position would be drawn tightly around the root of the lung and compressed Baccelli's idea was supported by Lizzato, Cardinelli and Fusa

Rosenbach has advanced the theory that such right-sided effusions are explained by the pressure exerted on the azygos vein by dilatation of the right heart This is aided by congestion of the liver caused by weakness of the heart The enlargement of the liver hinders the action of the diaphragm, and consequently prevents thorough emptying of the veins of the right side of the pleura, thus favoring an effusion

Just as the dilatation of the right heart appears to bear some relation to right-sided pleural effusion, so enlargement of the left heart, with or without involvement of the right side, was observed in nearly all the cases of left-sided effusion In the eleven cases of effusion confined to the left pleura, or greater on that side the left heart, and especially the left ventricle, was especially mentioned as enlarged in nine cases, that is, in four-fifths of the cases of left-sided effusion It seems fairly well established that dilatation of the right heart bears some relation to right-sided effusion The figures just given suggest also that enlargement of the left heart may bear some relation to left-sided effusion I can give no reason why this should be so The pressure of a dilated left auricle on the root of the left lung would not obstruct any large venous trunk analogous to the vena azygos major The venous drainage of the upper part of the left pleura is afforded by two small veins, the upper left azygos vein and the left superior intercostal vein These are so placed that they are not liable to compression by an enlarged left heart

Rosenbach explains these left-sided effusions by assuming that the enlarged left ventricle presses on the lower lobe of the left lung and produces atelectasis Long-continued congestion produced by the collapse of the lung brings about a low-grade inflammation of the pleura and finally an effusion forms in the pleural sac which is partly transudate and partly inflammatory

My list of cases gives nothing to confirm or to deny this theory of Rosenbach I can only call attention to the fact that left-sided cardiac dilatation seems to bear some relation to left-sided pleural effusion

Signs of acute inflammation of the pleura were not found at autopsy in any of the Presbyterian Hospital cases, or in any of those analyzed in my former paper Dr Stengel did not find any such condition in the three autopsies held on the cases he reports However, the fluid removed in Cases 1, 2 and 3 had too high a specific gravity and too large an amount of albumin for a pure transudate The fluid did not contain fibrin and was certainly not the result of an acute inflammatory process, but the physical characteristics of this fluid are such that it might have been the result of transudation combined with an exudate of a low-grade inflammation of the pleura, as has been suggested by Rosenbach

The pleura in Case 17 and in Case 4 of my previous paper were reported as thickened and whitened, although there were no signs of acute inflammation It may well be that long-continued congestion had set up some subacute inflammation here which was not active enough to cause fever, cough or pain but may have aided materially in the production of the effusion

Stengel suggests that a long-continued congestion produces some trophic change in the vessels of the pleura favoring the passage of the fluid and also calls attention to the fact that inflammation of the pleura may be latent and without symptoms He suggests that in some cases an inflammatory element may be present in the production of these cardiac pleural effusions

Gerhardt mentions a class of cases in which the effusion is very obstinate and recurs with great rapidity and persistence Some of these cases have been tapped a great number of times and the clinical picture they present is that of a chronic pleuritis of a low grade, combined with a process of transudation due to the congestion of the vessels of the pleura

Certain features of two of my cases suggest that some trophic change takes place in the pleura in cardiac disease that may render the pleura membrane a point of lessened resistance to infection

Case 13 was an instance of acute pleurisy which occurred on the right side in a case of well-marked heart disease, with cardiac dilatation and symptoms of failing compensation The pleurisy was accompanied by pain and fever

In Case 12 the empyema developed in a case of double cardiac hydrothorax, greater on the left side, after both pleural sacs had been emptied by aspiration The heart was much enlarged toward the left

These two cases suggest that long-continued congestion may have altered the tissues of the pleura and that the pleural sac had become a locus minoris resistentiæ Two isolated cases of this sort are not very convincing, but they are mentioned because they seemed to have some bearing on the question as to whether the effusion in cardiac disease is purely a transudate, or whether it is partly passive and partly inflammatory

It seems probable, then, that the mechanism of the formation of fluid in these cases of pleural effusion in heart disease is not that of a simple transudate, but that congestion of the pleura produces a chronic inflammation of low grade, and that the effusion is both a transudate and an exudate This is supported by the following facts First, the specific gravity of the fluid and the amount of albumin contained in it is often too high to be consistent with the pure transudate second the effusion may precede, by a considerable length of time, external edema or other serous effusions, third, the two cases reported suggest that the pleural sac particularly affected may undergo some trophic change, making it a point of lesser resistance to infection, fourth, the effusion in certain cases is very obstinate lasts a long time and returns quickly after aspiration

Gerhardt mentions the obstinacy and persistence of this effusion as a characteristic of this class of cases Rosenbach, Brouardel and Liebermeister have called attention to this peculiarity of such pleural effusions

Rosenbach mentions two cases in which the effusion lasted six and fourteen months respectively

None of my cases showed this obstinacy of the effusion in any marked degree Several of the patients were admitted to the hospital more than once for symptoms of failing compensation and pleural effusion, but usually one or two tappings were sufficient to relieve the dyspnea, and the fluid returned slowly, even when the case was near to a fatal termination

There was no case in the Presbyterian Hospital list in which the fluid persisted for any great length of time, and which was not relieved by one or, at most, two tappings The effusion usually disappeared spontaneously as the patient grew stronger, or else increased slowly until death Consequently, I can not say that the Presbyterian Hospital list supports the statement of Gerhardt and Rosenbach that great obstinacy is a characteristic of these pleural effusions in heart disease

PROLONGED DELIRIUM IN PERICARDITIS AND ENDOCARDITIS

WITH REPORT OF A CASE *

EDGAR MOORE GREEN, A M, M D
EASTON, PA

I have taken the liberty of bringing to your notice the subject of delirium in certain diseases of the heart, not because it was possible for me to demonstrate any new scientific theory, but rather because from my reading and my own limited personal experience it seemed to me that prolonged delirium in such cases was quite unusual It is, of course, well known that heart disease is a frequent complication of rheumatism, and endocarditis is much more common in such cases than is pericarditis According to Whittaker,[1] Bouillaud believed that in every case of acute articular rheumatism the heart was more or less affected Williams states that 75 are affected in every 100 cases Leudet fixes the ratio at 22 in 100, Sibson 20 in 100 Wunderlich 19 in 100, Duchek 16 in 100 Bamberger has claimed that 30 per cent of cases of cardiac trouble arise from rheumatism, and Thompson has placed the figures at 16 and 20 per cent. On the other hand, Latham states that pericarditis only occurs seven times in 136 cases of rheumatism The latter disease is certainly more apt to occur in severe cases, and is said to be more frequent when the inflammation has a tendency to wander from one joint to another in rapid succession It is said to occur very infrequently in cases of subacute or chronic rheumatism, in fact, some authorities deny that it ever occurs as a complication of the latter

Ordinary cases of the disease run a comparatively

[1] Twentieth Century Practice

short course, frequently not more than eight or ten days, except where the amount of effusion is great, and these terminate in from three to six weeks It will not be necessary for me to enumerate the ordinary symptoms and complications of this disease I may say, however, that the rarer symptoms mentioned by most authorities are aphonia and hoarseness, from pressure on the left recurrent or laryngeal nerve, syncope from anemia of the brain resulting from pressure on the large vessels of the heart or myocarditis, vomiting from pressure on the phrenic nerve Stupor, delirium and coma are mentioned as occurring from hyperemia due to pressure on the vena cava or to the accumulation of toxins in the blood All authorities whom I have consulted, however, have stated that the latter signs usually show themselves in the last stages of the disease Austin Flint has reported cases marked by delirium, but in all the cases of which I have read the delirium has been of comparatively short duration

It will not be necessary for me to give a detailed report of the symptoms of this case, but a résumé may be given as follows

History—Dec 15, 1902, I was called to visit a man, age 46, whom I found to be suffering from acute rheumatism His previous health had been good Early in life he was said to have had an attack of brain fever, but of this I could obtain no detailed history He had had two attacks of acute rheumatism, each lasting several weeks In one of these attacks he had been under my care, and, although the case was somewhat tedious, there were no complications and he made an uninterrupted recovery There was no specific history During the first week of his illness the inflammation was rather migratory in character, at one time an arm would be affected, on another day one knee would be inflamed, or one ankle or possibly both ankles, at another time an elbow or wrist During this time the temperature ran as high as 103 to 104 degrees At the end of about one week he was suddenly taken with pain in the left side about the level of the fifth and sixth ribs This pain was acute in character and accompanied each inspiration the respiration became more rapid, running up to 37 or 38 per minute, pulse 100 to 108, temperature 100 to 101 degrees

Examination—Auscultation at this time revealed symptoms of acute pleurisy, and also a systolic murmur over the precordium, but more intense at the apex There was also found a to and fro friction sound at the fourth and fifth interspaces directly over the heart The sounds of the heart rapidly diminished in force and loudness Visible impulse of the heart was practically obliterated Percussion of the chest revealed great increase in the lateral diameter of the cardiac dullness The urine was about normal in quantity but was quite high colored and of high specific gravity There was no albumin nor sugar, but urates were present in considerable excess

Symptoms—In addition to great pain in the region of the heart there was difficulty in swallowing The latter symptom was so marked that even the swallowing of liquids caused great discomfort and frequently he was unable to take more than one or two swallows in succession At the same time he became extremely restless, talkative and frequently saw imaginary objects It was exceedingly difficult to induce sleep Morphin, 1/4 gr, with atropin would partially relieve pain but seldom caused more than one hour's continuous sleep He was exceedingly restless, frequently trying to get out of bed and almost constantly trying to pick up imaginary objects His most frequent delusion was that he was traveling in some distant city or foreign country, although he usually recognized those about him After a number of days he believed he was on a sort of houseboat on a trip which his wife was conducting His usual question when I visited him in the morning would be, "Well, how did you get here today?" It is difficult to understand how this delusion could have originated His occupation for several years had been that of superintendent at large iron works and during certain seasons of the year he was in the habit of traveling for the making of purchases in various parts of the West At no time did his delirium become violent, though, as stated before, he frequently attempted to get out of bed This mental condition continued without interruption until January 26, or about five weeks, when, after a fair night's sleep, the nurse stated that his mind wandered but little After this time the mind was more or less confused for a few moments at a time each day for two weeks, but it may be said that the mental condition steadily improved From the time of the onset of pericarditis his temperature did not run above 100.4 degrees As a rule, it would fall to 99 or even 98.6 degrees in the morning and would rise to 100.2 degrees in the evening

Dyspnea was always present, though it did not develop to the extent of orthopnea Cyanosis was also present and its presence, of course, indicated the extent to which the brain must have been disturbed by this venous congestion Osler states in his practice that delirium and marked cerebral symptoms are associated with the hyperpyrexia of rheumatic cases I think, however, that you will agree with me that the degree of fever was not sufficient in this case to account for the continuance of delirium through so long a period of time

Treatment—December 31, Dr William L Estes of South Bethlehem was called to see the case in consultation The treatment adopted at this time was large doses of citrate of lithium and potassium with iodid of potassium three times a day Tincture of strophanthus was also given three times a day in doses of ten drops Fortunately for the patient the bowels were rather active, frequently four to five stools per day, and these were often more or less watery in character Under the action of the alkaline salts given with copious draughts of water, the kidneys became more active, the quantity of urine running some days as high as 102 ounces and not on any day being allowed to fall below normal The skin was kept active and perspiration continued profuse As soon as the patient's condition permitted general massage was given in order to tone up the general system

Result—Recovery, of course, was very slow, and he was not allowed to take up any work until March 31, even then the amount of physical exercise was much restricted In October, however, he started West on a business trip and much of his time was spent at great elevations above the sea level and yet with no untoward result On November 8 he left Durango, Colorado (elevation 6,520 feet), at 8 a m and went to Silverton (elevation 9,224 feet), where he walked two miles to a stamping mill and there climbed up to a height of 150 or 200 feet, afterward returning by train to Eureka The following day he drove twenty six miles alone, starting from Silverton (elevation 9,224 feet), and going to Ouray (7,700 feet), passing meanwhile over a height of 11,002 feet, then on nine miles further to Mount Sneffles (elevation between 11,000 and 12,000 feet), and back to Ouray at 6 p m

The ability to take such an amount of exercise at such an elevation would seem to me to show how thorough his recovery had been, moreover careful physical examination of the chest made within the last few days revealed no markedly unnatural sounds The cardiac impulse is normal in location and force and the sounds almost natural in character, except for a slight blowing murmur heard at the apex

---

How They Do It in Iowa—A Red Oak paper of August 20 has the following "Dr A A Potter, who advertised that he would be in Red Oak last Saturday and meet all who wished to have their ills taken away and their youth renewed, was on time all right But he met with grief a plenty He had no more than unpacked his pill box when a local officer arrested him and took him before Mayor Reiley to answer to the charge of practicing medicine in Red Oak without having procured a license The doctor plead guilty and was fined $20.10 He left town"—*Iowa Health Bulletin*

THE LIMITATION OF DIGITALIS IN MITRAL AND AORTIC REGURGITATION *

FRANK JONES, M D
MEMPHIS, TENN

While this subject has been thrashed over and ground up before various medical societies and by numerous eminent authorities, there yet remains much to be done in the crystallizing and refining process What I have to say may seem erratic and dogmatic to some, but I shall try to show by reason of the anatomic location and the physiologic action of the mitral and aortic valves that in mitral insufficiency when compensation has failed or is failing digitalis is the sheet anchor, the general in command while in aortic insufficiency with the same condition, it too often plays the rôle like the soldier, Jack Falstaff of old

In treating any heart lesion the careful clinician must study closely the cardiac state and the condition of the blood vessels, and he must take into consideration the various organs that are complicated

The mitral valve, located as it is, at the gateway between the great arterial reservoir the left auricle and the great arterial pumping station the left ventricle can, when it fails to close with systole throw its burdens on various organs, particularly the right heart the lungs, liver and kidneys When compensation has failed or is failing the pathologic picture is that of venous stasis

The column of blood is forced back on the left auricle This chamber of the heart can not perform its functions as a reservoir, receiving the blood from the pulmonary veins and sustain this backward flow at the same time As a result the pulmonary veins are obstructed in their efforts in carrying the systemic blood to the auricle The right ventricle has to contract against resistance It has to pump the venous blood of the right side through the lung already engorged from the backward pressure through the pulmonary veins, hence the marked hypertrophy of the right ventricle which ensues The lungs are overwhelmed, this condition giving rise to dyspnea as an evidence of edema, and to cough denoting bronchitis from irritation to the terminal branches of the bronchial tree This edema and bronchitis will be in proportion to the degree of obstruction and stasis, and the condition of the cardiac muscle

This backward pressure exerts its force further on the liver, giving rise to marked engorgement of this organ through the inferior vena cava, on the stomach, spleen and intestinal tract through the portal vein, on the kidneys through the renal veins Thus it can be seen that we have hyperemia of the lungs, liver, stomach, bowels and kidneys We have stasis everywhere, beginning at the incompetent valve and ending in a great many cases in the rectum, in the form of hemorrhoids It is seldom that one sees a classical mitral regurgitation with failing compensation but what hemorrhoids are also found All these organs enumerated have important functions to perform Nutrition is profoundly disturbed as a result of this stasis and engorgement The governing band of metabolism has run off The constructive and the destructive forces are in a state of unstable equilibrium We have perverted secretions, faulty excretions, bad nutrition, low blood pressure, vitiated blood and leaking blood vessels Dropsy, in mitral insufficiency, if properly treated, very often yields readily

With this clinical picture before you, with all the organs stagnated and overflowed, is there any necessity for dwelling on the marked effects of digitalis in mitral insufficiency with failing compensation? The very location of the mitral valve when the muscle becomes incompetent is conducive to marked hyperemia and venous stasis The right heart, in other words, must suffer the brunt of nearly all the evils as a consequence of failing compensation Now let us consider the other great valvular lesion, aortic insufficiency The aortic valve stands as a sentinel at the very gateway of life, the aorta This great blood vessel arises from the great pumping station, the left ventricle When this valve becomes incompetent from disease, and when the left ventricle fails to compensate and cries for help, it has not the neighbors to call on as the mitral valve has When it does sound the alarm and cries for help it is, alas, too often too late When the aortic valve becomes incompetent and can not close with diastole, we have a backward column of blood from the aorta thrown on an organ highly endowed with muscular structure, the left ventricle For a long period of time the left ventricle is the only portion of the heart that comes to the rescue of the incompetent valve when it cries for help The ventricle responds with vim and vigor It puts forth all of its energies Its fight and struggle is something to be applauded In its efforts to relieve the leaking valve it becomes enormously hypertrophied The beef heart attains to its most classic and highest degree in aortic regurgitation In nearly all cases of aortic incompetency there is naturally a high blood tension

There frequently exists a well-defined arteriosclerosis There is not the hyperemia of all the organs which we find in mitral insufficiency, except in the terminal stage when death is close at hand With this evidence before you let me ask, Has digitalis any place in aortic insufficiency? Nearly all of the eminent authorities teach us that when the left ventricle fails in its efforts to come to the rescue of the incompetent aortic valve, and becomes dilated and relaxed to such a degree as to produce leakage at the mitral valve, then digitalis is indicated

The argument is that this secondary or relative, or more properly speaking, muscular insufficiency on the part of the mitral valve gives the mitral symptoms of engorgement and stasis added to the aortic symptoms Therefore digitalis must be given, just as we would in a frank case of mitral insufficiency with failing compensation In other words they teach that failing compensation it matters not from what source, means digitalis as a remedial agent I wish to oppose these views most emphatically Digitalis in my hands has no place at all in aortic insufficiency, it matters not what may be the condition of the muscular structure of the heart The conclusions reached have not been on theoretical grounds as some of our authorities are so accustomed to charge but from a careful clinical bedside study in the hospital wards and in the outdoor clinic

As we said in the outset in mitral insufficiency with failing compensation it is the general in command It tones up the walls of the blood vessels by its vaso constrictor action It comes to the aid of the left ventricle which does not primarily undergo that marked hypertrophy which we have in aortic insufficiency By its actions on the ventricles particularly the right and the walls of the blood vessels engorgement is relieved blood tension is raised stasis is overcome absorption of serum through the blood vessels and lymphatics takes place

---

*Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Practice of Medicine and approved for publication by the Executive Committee Drs. J M. Anders Frank Jones and W S Thayer very often symptoms disappear and the patient is made fairly comfortable

As Broadbent well says in his book on diseases of the heart "Mitral insufficiency with dropsy is the disease that brings patients to the outdoor clinic Dropsy can be relieved, then symptoms can be materially alleviated so that they can resume for a time their occupation"

My experience at the outdoor clinic voices the sentiment so well expressed by Broadbent Dropsy, however, in aortic insufficiency means preparation for a funeral in a short while

It can readily be seen why this is so The ventricles, particularly the left, become hypertrophied and dilated, relaxed, worn out and degenerated *to such a degree* that the administration of digitalis is of no use

To give digitalis in aortic insufficiency, where we have secondary mitral leakage from ventricular dilatation, calls to mind the fable of the crawfish and the worm They became engaged in a heated argument Harsh words followed They challenged each other to a duel When they met on the field of battle the worm entered a protest that the crawfish had all advantage of him because he (the worm) *could not tell which end of the* crawfish to attack, because, as you know, the crawfish can move as freely backward as forward

So it is in giving digitalis *in aortic insufficiency with* failing compensation You do not know which end of the circulation the digitalis is going to attack In aortic insufficiency with failing compensation, where the mitral valve is relatively incompetent, we have leakage both at the mitral and aortic openings The leakage at the *mitral valve spins its force* backward with systole on the pulmonary veins, lungs and the right heart The backward current from the aorta through the incompetent aortic valve spends its force on the left ventricle

Let me ask the authorities who contend that digitalis is as much indicated in aortic insufficiency with failing compensation as in mitral insufficiency Does not the digitalis by its action drive as much blood back through the incompetent mitral valve as it does forward through the incompetent aortic valve? Does it not in this way increase the already existing stasis in the left auricle, pulmonary veins, lungs, right heart and liver? The authorities will answer by saying that digitalis will contract the ventricle, and by so doing will close the mitral valve, thus checking this backward flow, thereby relieving stasis

Let me ask When you close the mitral valve do you not put too much work on the left ventricle already overburdened from its continued efforts to come to the rescue of the incompetent aortic valve? Is there not danger by increasing this pressure within the *ventricle of* paralyzing the left ventricle already dilated to its utmost degree? Do you not put too much work on it while the coronary arteries are crying out for blood to maintain nutrition in the muscle? You are giving the heart more work to do and a stone for food while it is crying out for rest and bread

Dropsical symptoms in aortic insufficiency are very late manifestations They are the expressions of a heart tired *and fagged in its efforts to relieve* the incompetent valve and in the majority of cases the dropsical manifestations have their origin in the mitral and not in the aortic valve To give digitalis in these cases is like trying to make a wick burn when there is no oil in the lamp, or like trying to make an engine pull a heavy train up grade with the brakes on, with the flues burnt out and no steam in the boiler When compensation fails in aortic insufficiency *the left ventricle goes to pieces very much* after the fashion of Dr Holmes' masterpiece, "The Deacon's One Horse Shay"

Let me quote from our own Dr Babcock, in his most excellent book on diseases of the heart You may read between the lines just which way the pendulum is swinging in his analytical mind He says "In cases, therefore, of aortic defects manifesting dropsy, the indication is for the administration of cathartics and digitalis the same as in mitral disorders I believe, however, that the latter should be administered with judgment There are some physicians who advocate the employment of large doses of digitalis in all cases of aortic regurgitation with broken compensation My experience leads me to agree with Broadbent when he says that a distinction should be made between cases of aortic insufficiency with edema and those without When loss of compensation is shown *by* symptoms pointing to the left ventricle's feebleness, rather than by edema and back pressure consequent on relative mitral regurgitation, then I am emphatically of the opinion that digitalis must be given with caution" He cites the following case The *man had aortic* insufficiency with failing compensation He says "Edema was not present, yet the state of the heart seemed to call for heroic doses of digitalis in the forlorn hope of lessening the dilatation of the left ventricle Instead of doing *this, however,* the digitalis appeared to aggravate the back pressure, and at last death came suddenly and unexpectedly"

There is no more eminent authority on heart disease than Dr Babcock If you will follow him closely you will note that he qualifies to a great extent, the reference to digitalis in the treatment of aortic insufficiency with failing compensation He wants a string tied to the digitalis so that he can guide it

In my own experience, as I said at the outset, I can see no rational reason why digitalis should be given in this great valvular lesion Broadbent says in his book on diseases of the heart "In the absence of mitral symptoms it is rarely that digitalis is indicated in aortic incompetence or is of service, and it may undoubtedly do harm It may set up sickness, which is an ominous symptom in this form of disease and induces a condition of asthenia difficult to remedy"

In my opinion, this argument as set forth above can best be applied in aortic incompetence where mitral symptoms are present There is *more reason for* discrimination as to the indications for digitalis in these two valvular lesions than there is for the administration of quinin in the various malarial disorders The subject has always been of particular interest to me and I have reached the conclusion, after a careful study from *bountiful clinical material* that there is but one valvular lesion where digitalis is indicated, and that is mitral insufficiency, and not until compensation has failed

---

Tuberculin in Diagnosis.—The *Beiträge zur Klinik der Tuberkulose* is a new periodical just *entering its second* volume It is issued by Professor L Brauer of Heidelberg No 4 contains an article by Bandelier, of the sanatorium at Kottbus, who states that out of 500 persons to whom the tuberculin test was applied, 92 6 per cent responded positively All those who failed to exhibit the specific reaction have remained apparently healthy to date Out of 114 patients tested as they left the sanatorium, *38 per cent gave no reaction* and 22 of these patients tested again twelve to twenty months later, were found permanently cured with but 2 exceptions He urges the application of the tuberculin test as a current measure not only by specialists, but in hospitals and *in general* practice *In order to have a uniform* standard for comparison he pleads that Koch's technic should be followed

SOME POINTS IN THE ACOUSTICS OF RESPIRATION *

CHARLES E QUIMBY, M D

NEW YORK CITY

The first attempt to define, even relatively, the pitch of respiratory sounds was made by the late Austin Flint in a prize essay published in 1852 The opening sentences of that essay are as follows

> Very little attention has hitherto been paid to variations in pitch of sounds heard in the practice of percussion and pulmonary auscultation By most writers on physical exploration pitch modifications, except in râles, are not recognized, no allusion whatever being made to them

Flint makes essentially no attempt to explain the production of respiratory sounds, or to offer physical evidence in support of his purely dogmatic affirmations His statements as to the pitch of normal and pathic respiratory sounds, quoting verbatim, are these

> On placing the stethoscope over the trachea the respiratory sound is found to be notably high in pitch The relative altitude of pitch is immediately perceived on comparing the tracheal sounds with the vesicular respiration, heard on listening over the chest Two sounds are heard uniformly in this situation, viz, inspiration and expiration. The sound of expiration is higher in pitch than that of inspiration In vesicular respiration the pitch is uniformly and notably lower than that of tracheal and bronchial respiration The pitch of the bronchial sound is high, probably not much below that of the tracheal sound. In the more important elements the tracheal and bronchial sounds are similar, they are both high in pitch, and the expiration in each is higher than inspiration

The foregoing statements, made over fifty years ago are identical with those found in the standard works on physical diagnosis to-day, and have evidently been accepted through the intervening years by one author after another without question or investigation

In a former article[1] I presented a comprehensive discussion of the laws governing the formation of respiratory sounds and their pitch relations, and, as I believe, not only demonstrated the fallacy of accepted beliefs, but established, on a strictly physical basis, the truth of the exactly opposite propositions regarding the pitch and pitch relations of such sounds

It is the purpose of this present paper, reserving the right of reversion to the former article for exactness of statement under criticism, to present anew, in brief outline, a demonstration of the following propositions

1 The tracheal note represents the inferior pitch limit of respiratory sounds, and that limit may be defined by a letter of the musical scale, as may every other respiratory pitch

2 In vesicular respiration the inspiratory sound represents the superior pitch limit of respiratory sounds

3 The passage from vesicular respiration to bronchial breathing is attended, at first, by a lowering in pitch of the inspiratory note, and later by lowering of both inspiration and expiration

4 In vesicular breathing the inspiration is of a higher pitch than expiration, in rude, bronchial and tracheal breathing the inspiration is of a higher pitch than or the same pitch as expiration There is no respiration resulting from consolidation in which expiration is of higher pitch than inspiration

In the proposed demonstration it is necessary to consider first the formation of respiratory sounds Whatever modifications they may undergo later, there can be no question but what they depend primarily on vibrations excited in the respiratory air column by its motion through the tubes Any such confined column of air will be thrown into sonorous vibration when it meets or passes an obstruction whereby it is suddenly compressed Such points are found in the respiratory track only at the larynx and bronchial bifurcations At the larynx sonorous waves are produced by the primary compression of the air in passing the vocal chords, and the subsequent expansion as it enters the laryngotracheal tube, at the bronchial bifurcations similar waves are developed, on inspiration, by the deflection and compression of the air column, and on expiration by the impact of the two columns of air as they meet in a common tube Now, it is an established law of acoustics that the pitch note of any vibrating column of air is determined essentially by its length, and that the greater this length the lower the resulting pitch note In stating this law I am not unmindful of the measures employed by musicians in tuning such instruments as the clarinet and flute, they are but seeming contradictions of this law Hence, since pitch depends on length, the only supposition under which normal or vesicular respiration could be of low pitch, and bronchial breathing of higher pitch would be that the respiratory air column vibrates as a whole from the larynx to the ultimate tubes, which column would be at its longest, i e, lowest pitch in health and shortest, i e, highest pitch when its terminal was cut off by consolidation of the lung

If this were the case, however, there could not be two notes in the same tube, and vesicular and tracheal respiration must be of the same pitch, which we know is not true It is also made an impossibility by the physical conditions, since there is no constant tube length from the larynx to the terminal tubes, and the main air column could not vibrate in harmony with the various terminals Moreover, we know that a sonorous air column vibrates as a unite only within the limits of uniform compression These limits within the lung are the points of bronchial bifurcation It is thus evident that the normal respiratory sound, as heard at any given point, is a composite sound made up of the tracheal sound and an added term from each and every tube in the line of passage to and within that part of the lung under examination, and that each and every one of these component sounds has its own fixed pitch, determined by the length of the tube in which it is developed By reason of the manner of bronchial bifurcation the notes of the several components of this sound may fairly be represented by lines, of which one represents the trachea, progressively shorter ones the single branches, and multiple short lines the terminal tubes Now of these component notes, which combine in normal respiration and which represent all the possible respiratory notes, the trachea is the longest, and hence gives the lowest possible pitch note to be heard in respiratory sounds Whereby is established the first of our propositions For proof that the pitch note of this sound is, in the majority of persons, not far from G of the musical scale, I could quote high musical authority, but prefer to leave it to the decision of your own musical friends

In considering the question of pitch in the composite sound of vesicular respiration it is evident that there are three possibilities

1 These several components may be heard separately or in groups thus making vesicular respiration not one but two or more sounds each of distinct pitch As it

---

*Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Practice of Medicine and approved for publication by the Executive Committee Drs. J M. Anders Frank Jones and W S Thayer

[1] Medical Record March 25 1893

most certainly is not thus heard by the majority of diagnosticians we leave this contingency as not pertinent to the present discussion, merely stating that it is the case with those whose ears are acutely trained in the differentiation of pitch

Assuming, then, that but a single sound is heard in respiration, its pitch must be determined by some one or by a combination of similar-pitched components about which all the others are gathered as quality This dominant tone or tones will be that which reaches the listening ear with the greatest intensity

Therefore, we have for our other possibilities 2 One of the single notes, either that of the trachea or a primary bifurcation, may dominate the multiple short tube notes, in which case vesicular respiration will be of relatively low pitch 3 The multiple short tube notes may by reason of their combination, be the louder, in which case vesicular respiration will be not only relatively high, but the highest pitch respiration to be heard Which of these possibilities is the truth can be determined only clinically by the ear But leaving that point for the moment, some conclusions can be deduced from what has already been shown

It is obvious that, if the second assumption be true and vesicular respiration of low pitch, whether from the trachea or an early bifurcation, the short tube high pitch sounds are heard only as quality of the respiratory sound and their elimination under the processes of consolidation can only affect quality, and can not by any possibility make the resultant bronchial breathing of higher pitch than was the vesicular On the other hand, if the third assumption is the correct one, and vesicular respiration is of high pitch, by reason of the dominance of the multiple combined short tube sounds, then their elimination by consolidation can only leave the longer tube low pitch notes to supply pitch for bronchial breathing

Hence, under either contingency, vesicular inspiration represents the highest pitch of any form of breathing, it being under the second assumption, that of one of the single branches, and under the third relatively high from the terminal tubes, but in neither case admitting the possibility of a rise of inspiratory pitch during the consolidation of the lung

A justification for the decision of the ear in favor of the third possibility is found in a consideration of the factors determining intensity of the inspiratory notes As the air current is more rapid in the trachea and primary bronchi, their notes are primarily the more intense Each of these notes, however, is single and suffers a loss of both intensity and clearness by interference as its waves pass into succeeding tubes, while the terminal tube notes not only suffer no such disturbance, but gain relative intensity by their number and production close under the listening ear It is thus that ular

inspiration becom not only relatively and ly
of high pitch, b highest respiratory I e
heard, which gi ation for our s
third proposition

Turning now we see, since th
a composite soun in the same man
spiration, that ar of higher pitcl
spiration requires t of multiple
notes in still shorte inspiration

Two things, how is impossib
the manner in whic ations are
at any given bronchi On inspi
is by impact of the ai junc
bronchial walls condu

tion of such vibrations, on expiration it is by the colli sion of the two columns of air from the distal tubes, con ditions most unfavorable to the production of such vi brations Hence the note produced at any given point must be more intense on inspiration than expiration, and for this cause alone, other things being equal, it is evi dent that the distal point of sound production must be deeper in the lung, i e, in shorter tubes, on inspiration than on expiration

Second, the intensity of sonorous vibrations depend, other things being equal, on the pressure or rate of flow of the air column This is greater on inspiration than expiration, so that both factors of intensity thus combine to make the point of ultimate sonorous vibrations in respiration such as will give an expiration of lower pitch than that of inspiration What acoustics thus demon strates to be a necessity the ear confirms clinically, and establishes the fourth and last of our propositions in so far as it relates to vesicular breathing

It can hardly be necessary to repeat the demonstration for rude or bronchial breathing, since the same condi tions governing intensity are in force after the elimina tion of the short tube notes, until the sound heard i purely a transmitted note from some tube without the affected lung In such a case the inspiratory pitch may fall until it is the same as that of expiration, but it is impossible that it should fall below the expiratory pitch Thus we have established our final proposition for al forms of respiration

A brief word as to the manner in which inspirator pitch falls under varying grades of consolidation If th bronchial bifurcations and the consequent notes whic they contribute to the respiratory sound, were in geom rical ratio, i e, two at the first, four at the second, an thus on through, say, eight, sixteen, thirty-two and sixt four, and it was found that sixteen tubes, of any c note, were sufficient to dominate the lower notes, it wou then be easy to see that normal inspiration must h the pitch of the 128 notes, and that, as consolidation vanced from the surface, the inspiratory pitch wo drop successively and gradually through the pitch of 64 and 32 to that of the 16 But our assumption a bifurcation is not true, for, in fact, the bronchi, hence the respiratory notes, going to any given pa the lung, show two, or at the most three, large si branches and then a multitude of very small ones difference between these last and the single branche ing extreme from the acoustic standpoint As a r the dominance of these high pitch tubes in the res tory sound is not destroyed by the occlusion of a po of the number, but when such pitch control is fi lost by more extensive occlusion the change in in tory pitch is not gradual, but by a sudden drop to of one of the large single tubes, while such small as may still give sonorous elements now appear in t spiratory total as quality This explains how grades of rude respiration, which means rete higher pitch notes without pitch dominance, may pitch nearly if not quite so low as that of pure bro

bre With this change the pitch relations b
ins n and expiration remain unchanged
so ed am I that no form of pulmonary co
a respiration with relatively high pit
t for nine years I have had a standi
City Hospital for a case showing
That reward has yet to be claimed
ever in ten years I have heard such
hat was apparently for the individua

mal respiration In each case it was evident that the expiratory pitch was due to a peculiarity in the second branch on the right side, whereby the inspiratory high pitch notes were weakened and the expiratory current from the lower lobes impinged on the angle of bifurcation, as is the rule in inspiration

CONCLUSIONS

In conclusion, I beg to answer the question so commonly asked "Admitting all this to be true, of what good can it be to revise all our ideas, since men are making diagnoses by present methods?"

To this I reply 1 If it is the truth, it should be known accepted and taught 2 It makes available for purposes of diagnosis the full value of the element pitch in respiratory sounds, which, if the position taken is correct, has never been so employed heretofore 3 An experience of fifteen years in the teaching of physical diagnosis, making practical use of these principles with students, has shown that it enables students to acquire a far greater skill and confidence in diagnosis, within a much shorter time, than under the present methods of teaching"

DISCUSSION

ON THE PAPERS OF DRS STEELE, GREEN, JONES AND QUIMBY

Dr. James Tyson, Philadelphia—We should bear in mind that "the proof of the pudding is the eating," and I will simply state what I am doing in cases of aortic regurgitation with loss of compensation, which means that there is also regurgitation at the mitral orifice My first step is to place the patient in bed, I believe one half the battle is won by securing a complete relaxation and reduced demand on the heart—taking off the breaks as has been suggested—and this can often be accomplished only by rest in bed In bad cases I fortify this treatment with small hypodermic injections of morphin, scarcely ever exceeding one eighth of a grain, with probably some atropin added which softens the effect of the morphin These two measures will sometimes produce the most satisfactory and even unexpected results Having done this we are prepared to take more active measures toward the relief of the dropsy, and this can be done by active purgation, I go even further than this sometimes and puncture the dropsical tissues to allow the fluid to drain off and relieve the tension After this is done, and compensation remains unrelieved, I add digitalis, not in large but in small doses, say five minims every four hours, slowly increasing the dose, after waiting a reasonable time to get the primary effect I think very often physicians want to see the effects of digitalis before they should expect it I prefer to give moderate sized doses and then wait two, three or even four days sometimes, after which, if there is no contraindication, I may increase the dose In this way I think digitalis is helpful Dr Jones' illustration of the forward and backward movement of the crab is applicable, but I do not think the parallel is exact Of course, if there was an equal balance between the regurgitation at the mitral orifice and that of the aortic orifice, i e, if the blood came back as fast as it went forward, his position would be strikingly sustained, but so long as there is a chance of getting the blood to go forward more strongly than backward, I think we are justified in using digitalis I believe the general principles announced by Dr Jones are correct, and I agree with him, but I think we meet many cases which are successfully treated with digitalis, when there is mitral regurgitation with loss of compensation associated with aortic disease

Dr. Richard Cabot, Boston—Experience seems to show that digitalis may do good in uncompensated mitral disease, stenosis or regurgitation, in the vast majority of cases, and that it does not do good in aortic regurgitation I think a distinction should be made within the group of cases, known as aortic regurgitation, in elderly persons, with degeneration of the arteries and with high peripheral tension digitalis will do harm, but there is another and much smaller group of cases, occurring usually after rheumatism and in young persons In this group the disease attacks primarily both valves, mitral and aortic, the change being not merely a muscular one, but affecting chiefly the valves Here digitalis will do good, though not so much good as in cases of primary mitral disease I was struck with one of Dr Jones' figures about trying to haul a train up hill with the brakes on and with very little steam in the boiler Better let off the brakes than to try to make the engine do more work Better lower the peripheral resistance, if it is high, than try to stimulate the heart I have seen many cases where compensation had failed, and yet the heart seemed to be pumping strongly In these cases good results may be obtained by using purgatives and diuretics, and, when the dropsy is reduced, digitalis We should first deplete, reducing the load, and letting off the brakes, after that stimulation may be followed by improvement I take issue with Dr Quimby in all the points he has raised Music has interested me for many years, and particularly matters of pitch, and I wish to state that before writing my book on "Diseases of the Chest," I went through Flint and verified point by point everything that he stated regarding the pitch or respiratory sounds Dr Quimby is of the opinion that the pitch of bronchial breathing ought not to be higher than that of vesicular breathing, but he does not prove that to be the case My ear tells me that bronchial breathing is higher than vesicular breathing Also, it is my experience and that of my friends with musical ears that in bronchial breathing the expiratory sound is usually higher in pitch than the inspiratory one Therefore, I believe that what Flint has stated in his book is correct Anyone who is to consider this subject should have a musical ear, and should not base his remarks on the theory of the production of sound

Dr. DeLancey Rochester, Buffalo—I am in accord with what Dr Jones has stated regarding the use of digitalis in mitral and aortic insufficiency I think Dr Tyson will get better results with rest in bed than by placing his patients on digitalis in cases of aortic insufficiency There is one thing I wish to disagree with Dr Jones stated that the only place for digitalis was in failing compensation in mitral insufficiency, if he had stated "mitral disease" I would have agreed with him I think it has a great use in mitral obstruction In mitral obstruction the heart has great difficulty in forcing the blood from the left auricle to the left ventricle, digitalis will lengthen the time of diastole and will energize systole. Therefore the auricle is given more time in which to empty itself I think that there is a clear indication for digitalis in mitral obstruction We do not give drugs in cardiac diseases simply because we find a murmur, the use of drugs should be controlled by the condition of the circulation and evidences whether or not it is failing I am glad that Dr Cabot took issue with Dr Quimby, I also take issue with him, and I agree entirely with Dr Cabot Change of pitch is more easily recognized in the violin than in any other instrument known, and I must say that, clinically, Dr Quimby is wrong in the position he takes in this matter

Dr. S C James, Kansas City, Mo —A very unfortunate element in the make up of the heart is the fact that the valves are too close together, if I had the making of a heart I would like to separate the valves, five or six inches, then we western doctors would know when to use the whip, digitalis, and when not to use it The average physician, when he comes in contact with a case of heart disease, immediately thinks of digitalis I think that digitalis has done more harm in the world than it has done good On the other hand, I think that digitalis is one of the grandest remedies in the hands of medical men to day The lack of the intelligent use of this drug has placed many an unfortunate, though trusting patient, in his coffin If the cardiac condition were more carefully studied by the physician he would know better how and when to use digitalis I think if I was to lay the whip on a horse I would not do it at the foot of the hill I believe in the use of blarney, by its use a horse may be much encouraged and helped in pulling his load. Digitalis should be used, but with intelligence I believe, too, in taking off the brake, and, as Dr Tyson says, use digitalis moderately and with a great deal of caution

Dr Edward F Wells, Chicago—In the discussion and reading of Dr Jones' paper it must have been clear to everyone that the keynote to the situation in failing compensation in cardiac disease, so far as the management of the condition is concerned, is that of opportunity In the severer cases of lost compensation our opportunity for doing good is sometimes remarkable Take, for example, a man who has been sitting in his chair for days, with no sleep, with advancing swelling of the limbs, labored breathing, etc, and the management of such a case should be something like this Minute doses of morphin, 1/16 of a grain, administered hypodermically, will allow the patient to sleep for hours Cathartics should be given, and watery bowel movements should be obtained by giving elaterium, 1/8 or 1/10 grain doses every three hours, until eight or ten watery movements have been produced Then, if necessary, several punctures may be made in the feet or legs and you may allow quarts, or even gallons, of water to pass off within twenty-four, forty eight or seventy two hours Now comes the opportunity for the use of digitalis, and with the greatest benefit I am sure that if the members of the section will review their experience they will corroborate all that I have said

Dr Joseph Sailer, Philadelphia—Dr Steele's theory of the causation of hydrothorax is not capable of direct proof, and, therefore, depends on the accumulation of presumptive evidence There are certain facts which appear to be against it I believe that in the majority of cases of cardiac disease, hydrothorax is present when the left auricle is distended more than the right This opinion is based on careful percussion and examination of the heart Moreover, it is difficult to understand how sufficient pressure can be made on the vena azygos major to obstruct it without producing symptoms of pressure on some of the other important viscera of the thorax The dilatation of the cutaneous veins on the right side, which we should expect to occur on account of their anastomosis with the branches of the azygos vein, is not present, and, as Dr Steele has said, the theory is hardly applicable to the left sided cardiac hydrothorax, although there is little reason to believe that the etiology in the two conditions is different In regard to Dr Jones' paper, it has been my experience that aortic disease is more common than mitral disease, the proportion being about three to two When severe edema occurs in the course of aortic regurgitation and fails to clear up in three or four days after the patient has been put to bed, the prognosis is extremely grave Dr Cabot spoke of taking off the brakes The older writers, commencing with Laennec, used venesection freely and apparently with great benefit In those cases in which I have used it I have never known bad results

Dr Alfred T Livingston, Jamestown, N Y—The heart, as a pump, is a peculiar pump, being practically two double pumps combined and connected with each other One of the peculiar conditions which makes it differ from an ordinary pump is that it does not pump from a reservoir to a given point, but from the termination of one circuit into the beginning of the other Now, it is generally conceded that disorders of the heart have their primary cause in disturbances of the circulation If the two circuits are in perfect condition the pump will have easy work to perform and will not get out of order If it does get out of order, it is because something has gone wrong in one or both the circuits Therefore, it seems to me that the primary indication is to correct the abnormal conditions in the circuits Digitalis has been spoken of by Dr Jones as acting on the general circulation, but he regards it as a difficult creature to control and, therefore, to be used only with great skill My general experience with ergot leads me to say that I find it to be the best drug for correcting the fundamental conditions on which these cardiac difficulties arise Its action is certain, and is chiefly on the disordered tissues, unstriped muscular fiber, in using it you need not stop to consider where the circulation is disturbed If an overdose be given it will not do harm Its effect is to tone and contract the relaxed unstriated muscular fibers in the walls of the blood vessels from the crown to the toe, in so doing it helps the circulation I am quite sure that you will agree with me, when I say that if the general circulation is helped the heart will have a better chance to recover itself

Dr George W Webster, Chicago—Dr Jones has stated that digitalis should not be used in any case of aortic regurgitation, here I think we should discriminate and think of the condition which causes it In aortic regurgitation, when this is the only valvular lesion present, it is, as a rule, due to syphilis and therefore, is often accompanied by a general arteriosclerosis, here there might have been a widespread disease that started in the blood vessels and ended in the aortic valve On the other hand, aortic regurgitation is frequently found as a complication of, or exists with, other valvular disease, an obstruction at the aortic valve, as well as a regurgitation We should differentiate carefully between these cases of aortic regurgitation due to infection and aortic regurgitation secondary to syphilitic infection In the latter, Dr Jones will find that where there is a general arteriosclerosis of specific origin, there is no drug in the materia medica capable of doing more harm than digitalis On the other hand, where there is a simple infection and involvement of the aortic valve, or an involvement of the mitral valve as well, without involvement of the heart muscle, blood vessels, or kidneys, then it is possible to show that digitalis not only may but occasionally does good I think we should discriminate more than we do

Dr J M Anders, Philadelphia—Hydrothorax is a form of dropsy, or venous stasis, dependent on a passive hyperemia For its production there must be some obstruction to the venous circulation, and on the distal side of the obstruction fluid exudes from the lumen of the small veins The reason dropsy begins in the feet is because the venous obstruction is here reinforced by another causative factor, i e, the effects of gravitation In hydrothorax the influence of gravitation is not manifested, and yet we have all met with cases of pleural dropsy in which general dropsy was slight, or even entirely absent For an explanation of some of these cases, at least, it seems to me that the theory advanced by Dr Steele is tenable, namely, that within the thorax there is an obstruction to the venous circulation produced by abnormal pressure by the enlarged heart on the azygos veins Popoff and other clinical observers, and I myself, have observed inequalities of the radials in valvular disease of the heart, and I think this is explained by assuming that the right auricle exerts pressure on the large vessels within the thorax It is reasonable to suppose that the azygos veins might be pressed on and produce hydrothorax, although absolute proof is still wanting Cardiac dropsy is more common on the right than on the left side of the thorax, although it may be more marked on the left than on the right side Recently I saw a case in which it was confined entirely to the left pleural cavity There is a principle in the treatment of hydrothorax that should not be lost sight of When a cure results some of the fluid is obviously absorbed through the lymphatics, but it should be borne in mind that the fluid in hydrothorax is very poor in proteids, and may, therefore, be absorbed also through small veins As a matter of fact, there is no better way of getting rid of the dropsical fluid in hydrothorax than by systematic daily purgation by means of saline laxatives Venesection has a similar influence and exerts its good effects in the same way These measures rid the blood vessels of some of their serum and thus stimulate absorption from the pleural sac through veins and lymphatics to replace that which has been lost This should be done before the administration of digitalis The delirium which occurs in chronic heart disease is difficult to explain I have seen a number of cases which occurred after failure of compensation and where there was a general venous stasis I had occasion not long since to state that venous stasis should be looked on as a pathologic condition, it means, as Lazarus Barlow has pointed out, starvation of the tissues, the retention of waste products, and finally an anatomic alteration in the various viscera in the body, in just the same way as we have disturbances of the liver, gastrointestinal tract and the kidneys, so we may have disturbance of the function of the brain, or delirium There is another class of cases in which a different causative factor is at work, I refer to the blood changes—the toxic materials in the circulating blood These may produce heart lesions and general arteriosclerosis, and this sclerotic process may affect the cerebral vessels Here, coexistent cardiac disease and delirium may be met with before rupture of compensation has occurred In these cases I think the delirium is rather due to arterial changes within the brain than to any cardiac lesion per se, and that both of these organs suffer in consequence of the action of a common cause, namely, the altered blood state I believe with Dr Webster that we should classify our cases of aortic regurgitation into those due to endocarditis and those due to general degenerative changes before we begin to use any special method of treatment. I agree with Dr Jones that in aortic regurgitation, with marked arteriosclerosis, it is bad practice to give digitalis, and especially unguarded, in these cases it should be used cautiously only when indicated, and be guarded by the use of the nitrites or nitroglycerin, so as to diminish the arterial resistance

Dr N R Coleman, Columbus, Ohio—There are conditions in which digitalis does good, this has been my experience When we have a condition approaching a normal cardiovascular system, then we may secure good results from the cautious use of digitalis, but if there is a degenerative change in the blood vessels, such as an arteriosclerosis or some marked change in the heart, such as a granular degeneration then digitalis will not only do no good, but in the majority of cases it will be found to be a dangerous agent I take issue with Dr Quimby's theory While I am not a musician I believe my ear will detect matters of pitch pretty correctly I have studied physics, and especially acoustics, with care, and I do not believe the normal vesicular murmur is higher in pitch than the bronchial or tracheal respiration I will even go farther and say that the tracheal and bronchial expiration is higher than the tracheal and bronchial inspiration sound

Dr. J Dutton Steele—I agree with both Dr Sailer and Dr Anders in thinking that there has been no theory thus far advanced that can be called entirely satisfactory to account for pleural effusions in heart disease The theory that there may be some pressure on the various venous trunks within the thorax causing congestion and consequent effusion of fluid has a wide acceptance The vena azygos major curves around the root of the right lung and is, therefore, specially liable to be compressed The only point of practical value that can be drawn from our present knowledge of the subject appears to me to be that long continued congestion may cause effusion not as a mere obstruction to venous circulation but by reason of the long continued congestion causing some atrophic change, therefore, the effusion may not be entirely a transudation, but an exudation and therefore in these cases of hydrothorax I think we had better not wait and give purges digitalis, etc to relieve the dropsy but do early and frequent tapping

Dr E M Green—As has been stated in the discussion the cause of the delirium in pericarditis may be, 1, from hyperpyrexia which generally exists in these cases 2, from venous congestion 3 from the existence of some toxemia in the blood The fever however was not exceedingly high in the case reported and the delirium seems to have been caused by venous congestion

Dr. Frank Jones—I was glad to hear what Dr Sailer said regarding the frequency of mitral and aortic lesions It has happened to me to encounter more aortic lesions than mitral My experience has not been in keeping with the text books in this respect In regard to Dr Wells' statement regarding the general types of aortic insufficiency and the conditions which bring them about, I wish to say that, according to my own observation, when it occurs in early life the prognosis is invariably good In the endocardial form, the integrity of the heart muscle is not necessarily lessened, the coronary vessels are intact and the circulation is clear With regard to the remarks of Dr Tyson, I understand the position he takes in reference to the injudicious use of digitalis Particular stress should be laid on its use in approaching dissolution, when there is sleeplessness dyspnea much anxiety, etc

Dr C E Quimby—I am neither surprised nor disturbed that the gentlemen take issue with my statements I only regret that they have been unable to meet a logical demonstration of specific propositions with anything more interesting or pertinent than dogmatic personal opinions, as it affords me no opportunity for a reply

INTRACRANIAL NEURECTOMY FOR TRIGEMINAL NEURALGIA

CASES AND COMMENTS *

HARRY M SHERMAN, M D

SAN FRANCISCO

At this time and place one may not report opinions or cases which are merely conventional, and the report of the following five cases in four patients is permissible only because of the exceptions to the rules in two of them All were cases of trigeminal neuralgia, in all the pain had been of considerable duration, and had gradually become so severe as to be unbearable In all four patients the third branch was involved, in two the second branch as well, and in one all three branches In two patients the results were conventional Complete and lasting relief followed the operation In two patients, one of whom had two operations there were exceptional, unconventional accompaniments

In the first case the exceptional element was a complete and permanent paralysis of the facial nerve, noticed first the morning after the operation In this patient the pain had been limited to the third branch, but the intention at the time of the operation had been to remove the entire ganglion However, all that I did remove was the outer half of the ganglion with the second and third branches to their foramina of exit The wound healed aseptically, the pain was gone, but the seventh nerve was paralyzed Studying the possible traumatisms to the nerve during this operation, it is easy to exclude pressure on the pes anserinus, as the operation was done six or seven years ago, and on the lines of the original Hartley-Krause technic, so the zygoma was not cut and it stood between the nerve and any instrumental pressure by retractors, indeed, the osteoplastic flap of skin, muscle and bone was folded down over the zygoma and protected this very area On the other hand, while it is possible to reach back, inside the skull, into the posterior fossa, it is not conceivable that I let my finger wander so far as to pick up and tear the seventh nerve before it entered the petrous bone, and I am, moreover certain that I did not do this Finally, the man has had no trouble with his ear, nor anything to indicate disease of nor injury to the nerve during its passage through the bone

Excluding trauma to the nerve in its superficial location, put the case outside that class of which Pershing wrote and to which Wyeth the other day referred, and in which pressure or pull on a superficial nerve during the period of anesthesia resulted in temporary or permanent paralysis It is a satisfaction to do this, for the advent of the paralysis suggested this as the first and most obvious explanation and had it proved to be the true one, it would have had to be accepted as a fault in technic The integrity of the nerve before the operation and the lack of any pathologic ear or temporal bone process make it most probable that some injury inside the skull caused

the condition. I am aware that a man working by touch in the dark may easily reach farther than he intends, especially if he does not keep his eye on the external wound, but in this case the work was done by sight and not by touch, so that I can be sure an errant finger did not do the damage. The case was reported in The Journal some months ago, but no explanation has been offered and for this reason I include it with the other operations and submit it for discussion.

In the other patient the pain began in the supraorbital branch and was associated with an attack of herpes facialis. Primarily it acted as a definite neuralgia and the nerve was cut finally just above the orbit, but without giving relief. Then, because of a history of plumbism some years before, which had yielded to potassium iodid, because of miscarriages by the patient's wife, and because of non-response of the pupils to light, the potassium iodid was again given in doses of 5 grm. daily, with no local relief and with a distinct loss in general health. Thus the consideration of the case took cognizance of syphilis, but as treatment for syphilis proved of no avail and as the pain had extended to include all three branches, an exposure of the ganglion was decided on. It was also decided to cut the root of the nerve behind the ganglion and to go no further, unless some distinct pathologic process like a gumma should disclose itself. That this might be the outcome was the hope of Dr. Clark J. Burnham and Dr. L. Newmark, when they turned the patient over to me.

As I intended merely to cut the root, as has been practiced by Frazier, I prepared for the possible cutting of the sensory root only, so made my incision to circumscribe the temporal muscle. The muscle was then separated as a whole from the pericranium down to the point where the bone was to be cut. This also avoided unnecessary stripping of the pericranium from the skull in a putative syphilitic. At the proper level, about 1.5 cm. above the zygoma, the pericranium was cut and the skull bared. The zygoma was left untouched. A small trephine opening enlarged by rongeurs gave ample room. the exposure of the ganglion was uneventful and the fasciculi of the root were hooked up and cut, the cutting causing a reflex movement by the patient. It was not possible to discriminate between sensory and motor filaments, but the fact of the section of the entire root was satisfactory and the ganglion was tipped forward out of its bed to make this proof clear.

On coming to close the wound it was seen that the brain did not expand immediately to occupy its original space, and so, to avoid leaving an air space in the skull, normal salt solution was poured in and the head rolled over so as to keep it there while the suturing was done. For two days the man was free from pain and there was paralysis of the temporal and pterygoids. On the third day, however, he began to have pain, and this pain gradually increased in its old area and intensity. For two months the anesthesia, to light touches and to pin-pricks over practically the whole of the area of the fifth nerve, persisted and was verified by several examinations, while the temporal and pterygoid paralysis also persisted. In the third month sensation returned, to my surprise, and light touches and pin-pricks could be felt everywhere over the whole area excepting the supraorbital branch area which had been anesthetic from the time of the superficial section of that nerve. The sensation as it returned was not of normal intensity. It was described as being dull, but it was demonstrably present and evidenced a union of the cut nerve root beyond any doubt. The paralysis of the pterygoids, however persisted.

This is the supposedly exceptional point in this case. I do not know the number of cases operated on by Frazier and others in which the nerve root alone has been cut and nothing interposed between the ends, as was suggested by Abbe, but I was impressed with the simplicity of the plan when Frazier, on Spiller's suggestion, tried it and with apparent success. I report this case to call attention to the fact, which I am obliged to accept as proven, that the nerve root may unite and resume its function, and that this most simple operation is not, in itself, to be wholly trusted for the production of an anesthesia and an analgesia which will be permanent.

Because of the persistence of the pain, and also and chiefly, because of the return of sensation, I again exposed this man's gasserian ganglion, three months after the first operation. The point of interest here for me was the possibility of encountering such firm adhesions of the dura mater to the bone as to interfere with the operation. I followed, from the skin to the ganglion, the old line of operation. The incision was, therefore wholly in scar tissue, which nowhere was it impossible to discern. The dura mater was but normally adherent to the bone and consequently separated easily, and I attributed this to the salt solution, which presumably did not absorb quickly, which diluted any escaped blood, and so resulted in a light areolar tissue bond between dura and bone. A little hook, passed under the root of the fifth nerve, behind the ganglion, demonstrated that the ends had, by some kind of a bond, anatomic or cicatricial united. The union was broken, the ganglion tipped forward and wholly removed. Salt solution was again poured into the skull and the wound again closed and healed aseptically.

There is now a permanent anesthesia to tactile, heat cold and pain sensations except along the borderline between the fifth nerve distribution and areas of contiguous nerves, a line that is never a typical one and which permits because of its anatomic irregularity, of easy explanation of physiologic anomalies. It may be added that in this last operation the zygoma was cut and pushed down but that the addition to the field of view did not seem to me to be great.

Since this second operation the patient's subjective pain has continued unabated.

REMARKS

The points of the case are the variations of the incision so as not to injure the fibers of the temporal muscle nor strip more than the necessary amount of pericranium from the skull. The use of physiologic salt solution to fill the space to be occupied by a slowly expanding brain and exclude air. The fact that a ganglion can be exposed a second time, three months after the first time, with no difficulty and no hemorrhage, by following the lines and planes of the first incision. Finally the fact, on the evidence of this case, that the cut root of the fifth nerve may unite and resume its physiologic function. Other cases may be added to confirm this statement, but even if they are not forthcoming the fact of union in this one case can not, to my mind, be gainsaid.

Dr. Hoffa's Tribute to American Surgery.—In Dr. Hoffa's recent visit to this country he found much to commend in American surgery. He was greatly impressed with the completeness of American hospital appointments, especially the corps of nurses found in every large hospital. He praises the nurses for their intelligence and efficiency.

PHYSIOLOGIC EXTIRPATION OF THE GANGLION OF GASSER

FURTHER REPORT ON DIVISION OF THE SENSORY ROOT FOR TIC DOULOUREUX, BASED ON THE OBSERVATIONS OF FOUR CASES *

CHARLES H FRAZIER, M D
Professor of Clinical Surgery, University of Pennsylvania Surgeon to the University Hospital

AND

WILLIAM G SPILLER, M D
Professor of Neuropathology and Associate Professor of Neurology University of Pennsylvania

PHILADELPHIA.

From the William Pepper Laboratory of Clinical Medicine (Phœbe A Hearst Foundation)

REMARKS BY DR FRAZIER

In June, 1901, three years ago, I reported to the Section on Surgery of the American Medical Association then in session at St Paul, the results of a series of experiments on dogs conducted by Dr Spiller and myself, with a view toward determining the feasib of dividing the sensory root of the gasserian ganglion for the relief of tic douloureux

RESUME OF EXPERIMENTAL WORK

These experiments consisted in carrying out this operation on a number of dogs and subjecting the structures removed several months later to a rigid histologic examination to determine whether regeneration of the sensory root after simple division could occur The results of these investigations admitted of but one interpretation, namely, that there was not the slightest evidence of regeneration within the central nervous system. More recently,[1] Dr Spiller and myself pursued this line of investigation in a series of experiments on the sensory roots of the spinal ganglia with equally positive results

Having established by experimentation in lower animals beyond a peradventure of doubt the inability of the sensory root to regenerate at least within the central nervous system, it only remained to obtain equally positive results in the human subject before any substantial claims for the operation as a rational, practical and "tried-out" procedure could be made These we present to-day as a result of our experiments with four cases, all have remained free from recurrence

ADVANTAGES OF THIS OVER OTHER PROCEDURES

Extraction of the ganglion Certain theoretical claims were advanced in favor of the operation, and these have been substantiated by our clinical experience

1 *Control of Hemorrhage* —It minimizes the amount of hemorrhage No one can speak the truth and say that hemorrhage is not a troublesome feature Hemorrhage from the middle meningeal artery is of little or no moment, and it can be controlled easily whether the vessel be injured as it courses along the temporal bone or at the foramen spinosum On the contrary, hemorrhage from emissary veins is distinctly troublesome The greater the number and firmness of dural attachments, the greater will be the hemorrhage from this source, and the nearer we approach the ganglion the firmer the adherence and the freer the bleedin Inasmuch as the ganglion receives its greatest blood supply from below, surgeons are advised to put off elevation of the ganglion to the last To divide the sensory root the base of the ganglion is left undisturbed and this cause of free and persistent bleeding avoided

The only other source of hemorrhage worthy of consideration is the cavernous sinus Injury to this sinus has caused hemorrhage, if not serious and alarming, at least necessitating suspension of the operation for a day or more This vascular channel being in intimate relation with the internal aspect of the ganglion, is exposed to danger once the operator begins to free it from the ganglion Confining, as we do in practicing division of the sensory root, our manipulations to the root itself and to the posterior aspect of the ganglion work at the point of greatest safety, insofar as the sinus is concerned, and need never give it a thought

2 *Simple Technic* —Its execution is comparatively simple It goes without saying that the exposure of the ganglion is by far less difficult than its extraction. Once the ganglion is exposed, we have made all the preparations necessary for the division of the sensory root, thus this operation is complete before the difficulties common to the extraction of the ganglion have been approached

3 *Avoidance of Injury to Adjacent Structures* —The cavernous sinus is not exposed to injury The abducens is in such intimate relation with the ophthalmic branch that division of one is almost impossible without division of the other In the extirpation of the ganglion it is a matter of great difficulty to preserve this cranial nerve intact The motor root is always destroyed in extraction of the ganglion, whereas, in division of the sensory root, the motor root may be preserved intact

4 *Reduction in the Rate of Mortality* —If the troublesome difficult features attending operation for the extraction of the ganglion are, to a great extent, eliminated, there should be an appreciable reduction in the time required to complete the operation, and it is only reasonable to predict that the operation, which is more economical as to time and attended with considerably less hemorrhage, will be attended with a lower mortality

TECHNIC

This phase of the subject has been treated fully in previous papers[2] The approach to the ganglion by the usual Hartley-Krause method, the temporary or permanent resection of the zygomatic process, the exposure of the foramina ovale and rotundum as guides to the ganglion, an incision in the dura propria from one foramen to the other, the reflection of dura propria from the superior and posterior aspect of the ganglion revealing the sensory root, picking up of the root on blunt tenaculum and division of same completes the operation[3]

[*] Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Surgery and Anatomy and approved for publication by the Executive Committee Drs DeForest Willard, Charles A. Powers and J E Moore

[1] University of Pennsylvania Med Bul June 1903 p 126

[2] University of Pennsylvania Med Bul December 1901 Philadelphia Med Jour Oct. 25 1902

[3] Considerable importance has been attached to what has been called the intra arterial route and the difficulties attached to injury to the middle meningeal artery grossly exaggerated One familiar with the great variation in the course of the middle meningeal artery and its relation to the temporal and frontal bone realizes at once the futility of attempting to establish a point below which one can operate always with the assurance that the vessel will not be injured. The danger of injuring the middle meningeal vessel in opening the skull is due to the fact that the vessel sometimes runs in a bony canal, sometimes in a deep channel When the fragment of bone is removed the vessel is lacerated. Sometimes there is no canal at all usually the canal begins sufficiently high to escape injury exceptionally however the canal begins so far down that it would be impossible to make an opening large enough to enable one to carry out the necessary manipulations on the ganglion by the so-called infra arterial route Common sense prompts one to make the opening as near the base of the skull as possible not especially to avoid the artery but in order to reduce to a minimum the distance from the margin of the skull to the ganglion and to make the opening only as large as the manipulation may require No other directions to the operator are necessary he avoids injuring the artery if he can and if he can not it is a matter of no difficulty to control the hemorrhage

DIFFICULTIES ATTENDING THE OPERATION

An objection has been made to the operation we advise for the relief of tic douloureux, viz, that the sensory root can not always be exposed, and that in such a case resection of this root would be impossible Dr Spiller thinks it is extremely probable that resection of the posterior part of the gasserian ganglion would have the same effect as resection of the sensory root The object we strive for is the division of the central nerve processes which arise in the cells of the gasserian ganglion Many of the cells that send processes into the sensory root are cut off from this root by a resection of the posterior part of the ganglion, and the effect in the permanent relief from pain would probably be the same as though the sensory root were divided If, therefore, there is any difficulty in exposing or recognizing the sensory root Spiller recommends a resection of the posterior part of the ganglion, believing that it would be as effective as a resection of the sensory root

PHYSIOLOGIC EXTIRPATION OF THE GASSERIAN GANGLION

Up to this time the claims which have been made for division of the sensory root have been based altogether on the results of our own experimental and clinical evidence It might be well at this juncture to introduce the evidence of an impartial critic whose judgment and opinions in matters pertaining to the physiology, pathology and anatomy of the nervous system are held in great respect Van Gehuchten has published recently a most instructive and interesting paper on the surgical treatment of trifacial neuralgia,[4] and in this article he discusses somewhat at length the effects of division of the sensory root Owing to the fact that he believes this operation to be as radical in effect as extirpation of the ganglion, he has styled the former not inappropriately the "physiologic extirpation of the ganglion," and regards it as both less dangerous and more complete than the operation of Krause

His observations and conclusions on the question of regeneration or degeneration of the sensory root confirm absolutely our own Every fiber of the central nervous system, he says, attacked by secondary degeneration is a fiber inevitably lost "The nerve fibers of the central nervous system interrupted at any part never regenerate The section of the large root of the trigeminal nerve is equivalent, then, at least as regards its effects on the bulbo-spinal root, to the destruction or extirpation of the gasserian ganglion itself Whether the cause of the trifacial neuralgia resides in the semilunar ganglion, or in one or the other of the three peripheral nerves, at the moment we interrupt completely all communication between the ganglion and cerebrospinal axis, we destroy inevitably the route by which painful impressions are conveyed to consciousness

"The section of the large root of the trigeminal nerve, even though it does not constitute an anatomic extirpation of the semilunar ganglion, is equivalent, then, to a true physiologic extirpation, and is the only one which is of importance in point of view of treatment of trifacial neuralgia

"This physiologic extirpation is not only more complete and easier to accomplish than the tearing out of the ganglion recommended by surgeons, but it has an advantage over this mode of operation which is not to be despised It leaves intact the connections of the ganglion with the peripheral organs"

That the operation on the root is much more simple than the extirpation of the ganglion might be inferred from the fact that many surgeons, among them Poirier, Horsley and Lauwers, recommend tearing out the root as a preliminary measure to extirpating the ganglion If the exposure of the root were a matter of any great difficulty, this step of the operation naturally would have been postponed until the last when the ganglion was entirely freed from its attachments

It has been said that the suggestion made by Dr Spiller, in 1898, of treating tic douloureux by division of the sensory root was not original, that there was on record one instance in which, prior to 1898, the operator had deliberately torn out the root This is quite true, but it should be borne in mind that the surgeon did not perform this as an operation of choice, but did it because he was unable to remove the ganglion His patient died within a few hours, and he never repeated the operation nor recommended it to others For the conception of the idea that division of the root was equivalent to physiologic extirpation of the ganglion credit is due to Spiller alone Furthermore, those who have taken exception to the claim of originality ought to have known that there is a very distinct difference between avulsion of and division or resection of the root Avulsion of the root is not only unnecessary, but what is still more important, may be distinctly harmful Simple division of the root suffices to cause complete and persistent degeneration of the bulbospinal root of the trigeminal nerve, and the possibility of recurrence of the symptoms is therefore *nil* Avulsion may expose even the pons to concomitant lesions (Van Gehuchten), and for this reason alone the procedure should be rejected

AVOIDANCE OF OCULAR DISTURBANCES

Noteworthy in our experience is the absence of any ocular disturbances Attention has already been called to the frequency with which the structures on its inner aspect, including the third, fourth and sixth nerves, have been injured in extirpation of the ganglion, and to their escape from injury in division of the sensory root The most serious ocular disturbances of extirpation of the ganglion is corneal ulceration Although no especial pains have been taken to guard against it, our cases have been entirely free from this complication Spiller says it is probable that sympathetic fibers pass to the eye after entering the trigeminal nerve through the gasserian ganglion, and as in division of the sensory root these fibers are not injured, the danger of ocular disturbance by this operation is lessened The trophic influence of the gasserian ganglion on the eye may possibly depend on the integrity of these sympathetic fibers, but it is probable that these fibers are not so numerous in man as in the lower animals (The literature bearing on this subject has been carefully studied by Kreuzfuchs) Of this phase of the subject, Van Gehuchten writes "The persistence of the anatomic connections between the peripheral organs and the gasserian ganglion, separated from the nervous axis, without doubt, prevents the grave ocular complications mentioned by Kraus and Lauwers" The experimental investigations of Van Gehuchten himself and of Lugars and Bonne have shown that while degeneration of the fibers of the central stump follows division of the sensory root the ganglion itself does not undergo any marked modification This is equally true of the posterior roots of the spinal cord and their ganglia as of the cranial nerves and their ganglia

METHODS OF ABBE AND VAN GEHUCHTEN

Recognizing from his wide experience the difficulties and dangers that attend extirpation of the ganglion, Abbe recommended another operative procedure, because it was very much safer and, in his opinion, equally efficacious This consists in division of the second and third divisions at their exits to their respective foramina and the subdural interposition of tissue Two objections to this method of treatment at once suggest themselves The first that the operation is applicable only to those cases in which the pain is distributed only to the second and third divisions, the second that there is a possibility of the rubber tissue acting in the rôle of a foreign body setting up a reaction in the tissues, which would terminate in abscess formation and necessitate the removal of the foreign material

Abbe says "It is certainly past dispute that there is no need for the removal of the first branch of the fifth pair in any case of grave tic douloureux unless the origin is to be found in a tumor of the gasserian ganglion or behind it" This may apply to the majority of cases, but it certainly is not a rule without exception In fact, in two of the four cases which constitute this series, the pain was most intense in the distribution of the first division

It might also be said of Abbe's operation that it offers no assurance against subsequent involvement of the first division, and so far as the mortality is concerned, it should be no less than that following division of the sensory root, since both are intracranial operations, the only difference being that in one two peripheral branches are divided, while in the other the central root of the ganglion

Van Gehuchten, in his recent contribution to the treatment of trifacial neuralgia, recommends the tearing out of the peripheral branches, a procedure which, he says, is simpler and much more easily executed than intracranial resection This recommendation is based on the following phenomena Simple division of a cranial nerve nearer to or further from the base of the cranium is followed by degeneration of all the cells of origin, but with complete integrity of all or almost all of the fibers of the central end This degeneration is only temporary, however and is soon followed by reparation of the nerve and restoration of the function Tearing out of the nerve, on the other hand, produces reactional phenomena much more intense, the degeneration that follows soon becomes an achromatosis, and this, in turn is followed by atrophy and disappearance of all the injured cells These phenomena have been observed only in motor nerves, and to prove whether sensory nerves would be affected in a similar manner, experiments were conducted on rabbits, the three peripheral branches were seized with a hemostatic forceps at their exits from the supraorbital, infraorbital and mental foramina and torn away The results were positive, not only was there atrophy of the cells of the ganglion, but Wallerian degeneration of its bulbospinal root

As regards the technic of the operation, the nerve should be freed as far as possible from all its connections and seized as near as possible to the base of the cranium, in order to make the resulting traumatism more intense In reviewing the literature of the subject, Van Gehuchten found that this operation had been recommended and practiced by Blum in 1881, and later by Doyen There seems to have been some apprehension on the part of surgeons that there was danger in employing the force necessary to tear the nerve, of inflicting some serious injury to the brain centers In any other cranial nerve this complication might occur, but the gasserian ganglion is so firmly attached to the base of the skull that this accident could not be considered possible

These observations of Van Gehuchten are certainly worthy of the surgeon's consideration If avulsion of the nerve will result in such degenerative changes of the ganglionic cells and the bulbospinal root that restoration of function is impossible, this operation should be practiced as a substitute for the intracranial operations Whether or no surgeons at large would be willing to practice in those cases in which a so-called central operation is indicated, it should at least be given a trial, when circumstances call for a peripheral operation, that is to say, instead of resecting a portion of the inferior dental or infraorbital nerve, the nerve should be forcibly torn away If Van Gehuchten's observations are correct, it is reasonable to assume that there would be less chance of recurrence in the case of the latter than of the former operation Not, of course, until this operative procedure has been proven successful in its application on the human subject can it claim the support of the surgical profession Therefore, with the exception of a few isolated cases, it is supported only by the results of experimentation on rabbits[5] Davis, in 1898, operated on a case in which this idea of Van Gehuchten's was put into practice, but with unfavorable results The superior maxillary nerve was exposed as it ran from the gasserian ganglion The nerve, as it entered the bone, was grasped with a hemostatic forceps and pulled upward, with another forceps the nerve was grasped closer to the ganglion and twisted loose from it The relief which followed the operation was only temporary, the pain gradually returned and became so severe as to require a more radical operation In commenting on the case, Davis says the explanation of the return of pain is left to the experts The operation was practiced in the manner prescribed by Van Gehuchten, it might be claimed that the twisting out of the nerve was not sufficiently violent or brusque, but this view is hardly acceptable

REMARKS BY DR. SPILLER[6]

In studies of the nervous system of dogs,[7] in which the sensory root had been cut, I found that when only the external part of this root was divided the degeneration in the spinal root of the trigeminal nerve of the pons and medulla oblongata by the Marchi method was only in the dorsal part of the root This is well shown by photographs in the article referred to I believed from these investigations, published in December, 1901, that I was justified in concluding that the fibers of the lateral portion of the sensory root at its entrance into the pons, in their further course, occupy the dorsal part of the descending spinal root From this it follows that the fibers of the inner portion of the sensory root occupy the ventral portion of the descending spinal root

The investigations of Van Gehuchten on the changes occurring in the sensory root of the trigeminal nerve, after tearing out peripheral branches of this nerve are important He says, in relation to this subject "This

[6] The following observations on the relative position of the fibers belonging to the three peripheral branches of the trigeminal nerve in the gasserian ganglion and the sensory root and their continuation in the spinal root are by Dr Spiller including an explanation for the limited area of anesthesia of the face occurring after partial division of the sensory root.

[7] Spiller and Frazier University of Pennsylvania Med. Bul December 1901

The local reaction was very slight, with no necrosis of tissue and little swelling or edema, no paralysis (It will be noted here that the injection was not made into the nerve trunk, but around it, nor was the acid injected into the foramina)

The toxicity of osmic acid as shown by Naunyn, Gmelin, Husemann and Brauell is mild, and only in doses of 2 grams or more, administered by the stomach, does it prove fatal to animals But one fatal case in man was reported by Raymond, the dose not given It is safe to say that administered hypodermically it is free from constitutional reaction

Osmic acid injections for peripheral neuralgia, says Joseph Lipburger,[3] were first recommended by Neuber of Kiel Osmic acid was used by Nicoladoni in a case of trifacial neuralgia of nine years' standing, originating in the supraorbital nerve, which was resected, and the pain then appeared in the infraorbital and mandibular branches These were each resected in succession and it then recurred in the supraorbital, six years after the first resection Sensation had returned in the whole face notwithstanding the resection of all the facial nerve branches and the mandibular, even up to the angle of the jaw, though it was not perfect compared with the opposite side, it was practically restored Patient, October 16-22, received six injections of 7½ m of a 1 per cent solution into the supraorbital area There was some gangrene after the second series of six injections of 2 cm of a 1 per cent solution This was slow to heal and left a dark scar The gangrene is attributed by Lipburger to the excessive quantity used so close to the skin (In this view I concur, while I have had no such result following any of my cases, there is a deep necrosis of the area around the point of injection) The pain in this case was absent for a year after the injection was made There was no incision made in Neuber's or Nicoladoni's cases, and no effort was made to inject the solution into the nerve substance, as was done by Mr Bennett The effect was supposed to be exerted on the peripheral nerves and not on the trunks It was cheerfully commended by Leipsiger, but dropped out of general observation until restored by Bennett

Jacobi[4] treated 18 cases of neuralgia with subcutaneous injections of 1 per cent osmic acid, giving one-half to one syringeful, of these, 8 cases, among which were 5 sciaticas, were cured, 2 improved, and 8 not cured It is most efficacious in inveterate sciaticas Application is not without danger Radial paralysis followed an injection into the arm

J Mercer[5] reports favorable results from deep injections of 1 per cent osmic acid in sciatica Relief following one to four injections between the tuber ischii and the trochanter major was temporary, though in the later cases there was greater relief than after morphin injections Twelve injections were made in one case

B M Schapiro[6] treated 8 cases of trigeminal neuralgia with subcutaneous injections of osmic acid (3 males and 5 females) Two males and 3 females were cured, 2 improved 1 unimproved He recommends osmic acid 0 1, water 6 0, glycerin 4 0 About twelve injections Bad results occurred only once in an epileptic woman He believes the result to be due to corrosion (aetzung) of the terminal branches Even though there are no cures and recurrences take place, the method is to be warmly recommended

W H Bennett[7] treated 12 cases of neuralgia with injections of 10 to 15 m of 1 per cent solution of osmic acid Ten cases were trigeminal, several of them with very severe symptoms (tic) One case an amputated stump in which the popliteal and peroneal nerves were injected In one case where the median nerve was injured and thickened with paralysis of long standing, the injection was made below the point of thickening, results were favorable in all cases Bennett laid the nerves bare by a short incision and injected 10 to 15 m of the solution into the nerve trunk, changing the position of the needle three times The cases were all obstinate Symptoms were alleviated in a few hours and disappeared within a few days There were slight recurrences in 2 cases—one in a different area, e g, that supplied by the auriculotemporal branch when the original pain was in the infraorbital Bennett operated on his first case in May, 1897 He believes the method ought to be applied early

PATHOLOGY OF TRIFACIAL NEURALGIA

The changes described by pathologists who have had opportunities to examine avulsed ganglia from operations, or to make postmortem examinations of the ganglia of trifacial neuralgia cases, are almost as varied and diverse as the number of investigators Hence it would be fair to say that there is no definite well-defined pathologic lesion that is found with anything like uniformity However, this does not detract from our interest in the pathologic findings reported by different investigators There is also a great divergence of opinion as to nerve changes proximal to division of the sensitive fibers or of the posterior roots of the spinal nerves, as well as the regeneration and degeneration of the trifacial

G Marenghi[8] made 127 experiments on animals, using the sciatic nerve He believes the following conclusions are established

1, Electric inexcitability in the scar, 2, impossibility of transmitting electric excitation through the scar, 3, excitability of the central stump, 4, excitability of the peripheral stump above the scar

The re-establishment of motor function is not indissolubly connected with regeneration of nerve fibers, but that function in a given territory may be re-established by collateral nervous paths, e g, the crural after-division of the sciatic

Keen and Spiller[9] remark that in six of their seven cases the lesions were intense in degree and unquestionable In the ganglia the medullary sheaths and axis cylinders were much swollen, the fibers atrophied, the sheaths empty, with nerve bundles in which the nerve elements had been destroyed and only connective tissue was left The ganglion cells were atrophied and stained faintly the blood vessels were sclerosed and even in some cases without a lumen

Garre,[10] in writing on nerve regeneration after extirpation of the gasserian ganglion, and the cause of the return of trifacial neuralgia, says the majority of trigeminal neuralgias are located in the peripheral nerves, therefore, recurrences after resection are not surprising and are due to this regeneration In one of Garre's cases, in spite of resection of the gasserian ganglion the second and third branches of the trigeminus were regenerated, the former twice He offers as explanation of the recurrences

1 Hysteria (I do not consider this of any value, merely another expression for an absence of definite knowledge)

2 Seat of neuralgia in the brain center

3 Regeneration of nerves through anastomosis or imperfect resection of the ganglia

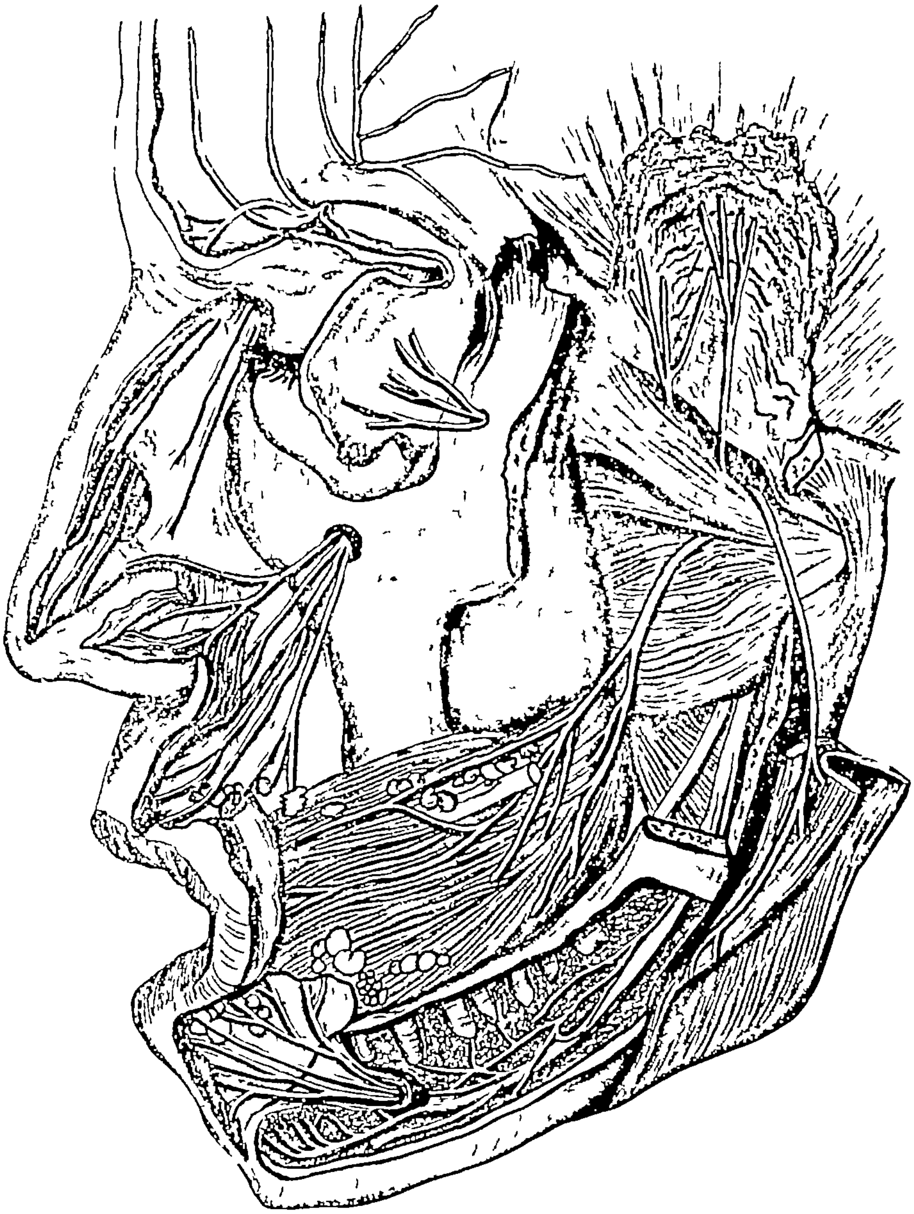

Fig 1 —Shows the supraorbital in two divisions the infraorbital the submaxillary or mandibular and the lingual branches (From Toldt)

In his cases cited above there was no question as to complete removal of the ganglia

I F Barker[11] examined two cases using Nissl's method There were scarcely any normal appearing cells in some there was an absence of tigroid bodies Some of the nuclei were swollen there was no typical Marchi degeneration no pigmentary changes in cells, no vascular changes and no interstitial hypertrophy Concentric bodies were present

T C Renton[12] reports examination of two ganglia in which there was absolutely no abnormality

Schafer[13] states Van Gehuchten and Nelis observed that sensory nerve cells of the vagus ganglion disappeared after cutting fibers If this were true of other sensory nerves it would be difficult to see how they could ever regenerate Restoration of function would have to be explained by ingrowth of sensory fibers from other areas of distribution Other observers have not confirmed these statements as far as the spinal root ganglia are concerned

Sidney I Schwab[14] collected 20 cases from the literature in which ganglia were examined after removal Few of these cases will stand criticism He also examined two cases, in one of which the nerves had been resected ten years previously In both cases the nerve cells must be regarded as pathologically altered, but in neither to such an extent as to consider them permanently affected The definite changes usually found in acute or long-standing parenchymatous nerve cell affections are absent The more marked changes in one of the cases lose significance from the fact that the nerves were previously resected Neuritis and atrophy were probably present The concentric bodies of brain sand found in one case and which have been described by Barker and Spiller are probably corpora amylacea Their pathologic significance is probably *nil* He concludes that trigeminal neuralgia has no definite pathologic entity That it is

[13] Text book of Physiology London 1900

[14] Annals of Surgery vol xxxiii 1901

1 A neuritis beginning in the terminal divisions of the fifth nerve, and having a tendency to ascend to the ganglia

2 An interstitial inflammation, chronic and progressive, of the ganglion itself

3 Central neuralgia or neuritis, affecting the sensory root as it leaves the pons

He believes also that wherever the process is located, removal of the ganglion must be the first means of relief

Krause in his report (Die Neuralgie des Trigeminus), of the study of four cases of trigeminal neuralgia, remarks that the ganglion cells showed pigmentation, vacuolization and atrophic appearances There were no changes in the blood vessels and no interstitial neuritis He believes that the changes are, first, parenchymatous in nature, and, second, that the myelinized nerves are involved later

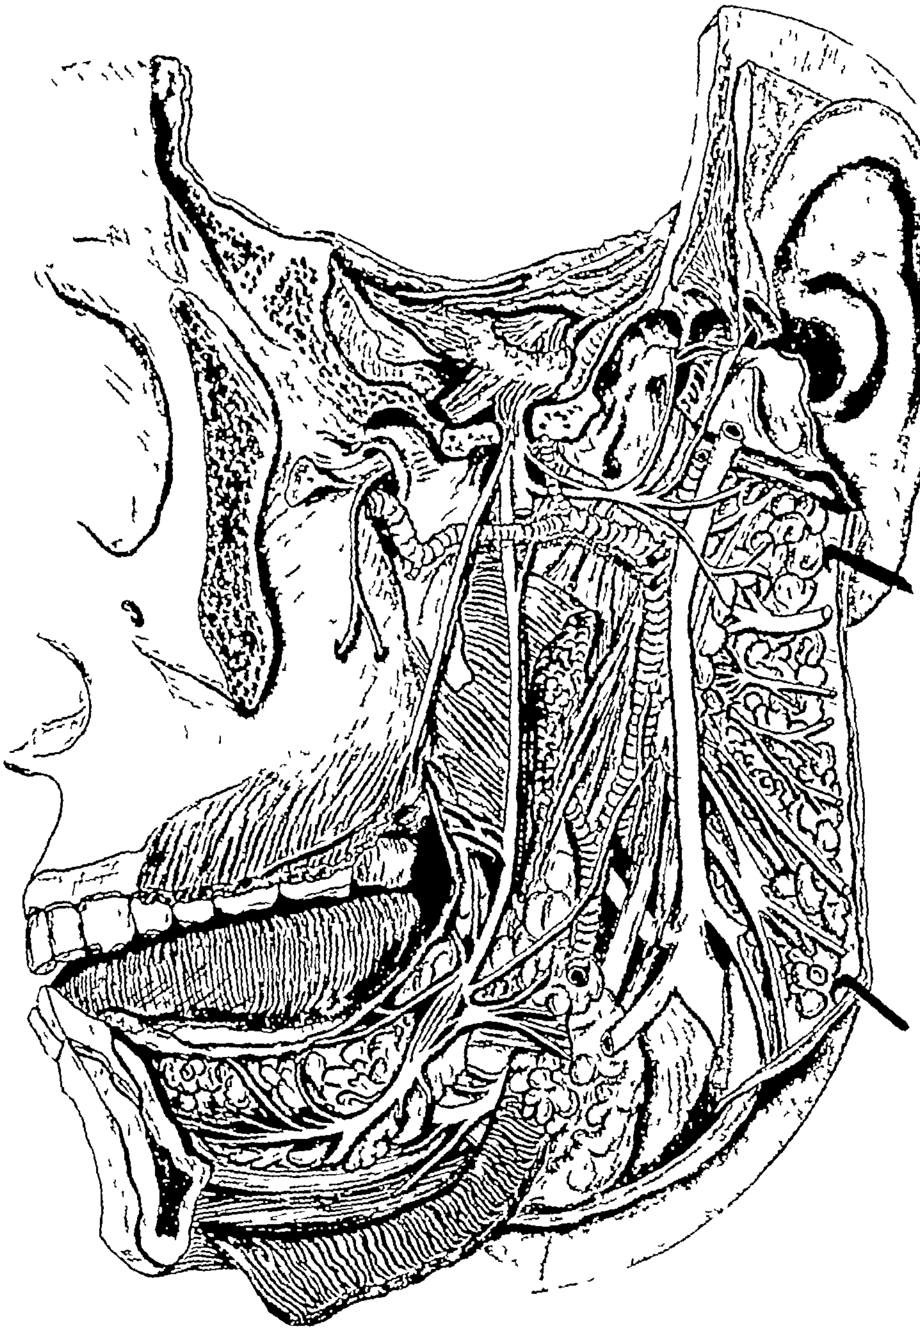

Fig 2—Shows the ganglia and the relations of the branches at the exit from cranium as well as the glandular divisions (From Toldt)

P L Friedrich[15] reports a case of recurrence on both sides after complete successful exsection of the ganglion on one side He explains this—according to Garré's hypothesis—that by means of nerve regeneration and collateral nerve branches the sensory trigeminus center is certainly brought into communication with the periphery (This, we believe from our observations, comes nearer to the true explanation of the recurrences of trifacial neuralgia)

W G Spiller and C H Frazier[16] report the division of the sensory root of the trigeminus for the relief of tic douloureux The sensory roots of the trigeminus were resected in dogs Experiments were not conclusive, but rather contradicted regeneration A canvass of the literature convinced them that regeneration had not been established in man and that no recurrence of its function was known after resection of the sensory root

[15] Deut Zeitschrift für Chirurgie, vol III p 360

[16] Univ of Penn Medical Bulletin, December 1901

They again report[17] the division of three posterior roots in dogs The animals were killed at the end of ten months There was absolutely no trace of regenerated nerve fibers in the cord The intramedullary portion of the roots was completely degenerated

Spiller and Frazier[18] further report on the treatment of tic douloureux by division of the sensory root of the gasserian ganglion The rationale of the operation depends on the inability of this root to undergo regeneration They proved that only those nerve fibers provided with sheaths of Schwann have the possibility of regeneration This was confirmed by Ballance and Stewart[19] Therefore, regeneration of peripheral nerves is common, while regeneration of the nerve fibers of the central nervous system is rare, if it occurs at all This leads to revival of the old theory of peripheral regeneration

After resection of the sensory root, if nerve fibers have grown out from the sheath of Schwann, they can only go as far as this sheath is present, i e to the point of entrance of the sensory root into the pons They report one successful case with complete anesthesia at the end of one year

The findings reported by Spiller and Frazier from the division of the posterior roots in dogs do not correspond with those obtained by Y Bikeles in the Physiologic Institute of Prof A Beck[20] in Lemberg This author showed by experiments that after compressing the posterior roots there are slight attempts at regeneration, contrary to the theory advanced that there is no intramedullary regeneration

No positive evidence has been obtained to show that regeneration of nerve fibers takes place within the nerve centers after artificially produced lesions It is remarkable, however, that outside of the nerve centers or ganglia the nerves are regenerated and that the regenerated fibers find their way along the old nerve sheaths to the same structures to which they were distributed before section or degeneration occurred Regeneration on the distal side of division of a nerve cylinder is readily understood, as the cylinder is merely an extension of the cell from its nucleus, and cell portions do not long survive when they are disconnected from their nucleus It is well recognized that distal degeneration takes place early in motor fibers after division and that proximal degeneration advances slowly, probably from non-use, as after amputation This may account for the absence of degeneration in specimens obtained in our first experiments, as the time was so short, but the paralysis was complete and continuous The portion of the nerve cut off from the central cell nucleus always undergoes degeneration Even after division ascending degeneration is limited to a small distance, after division of a sensi-

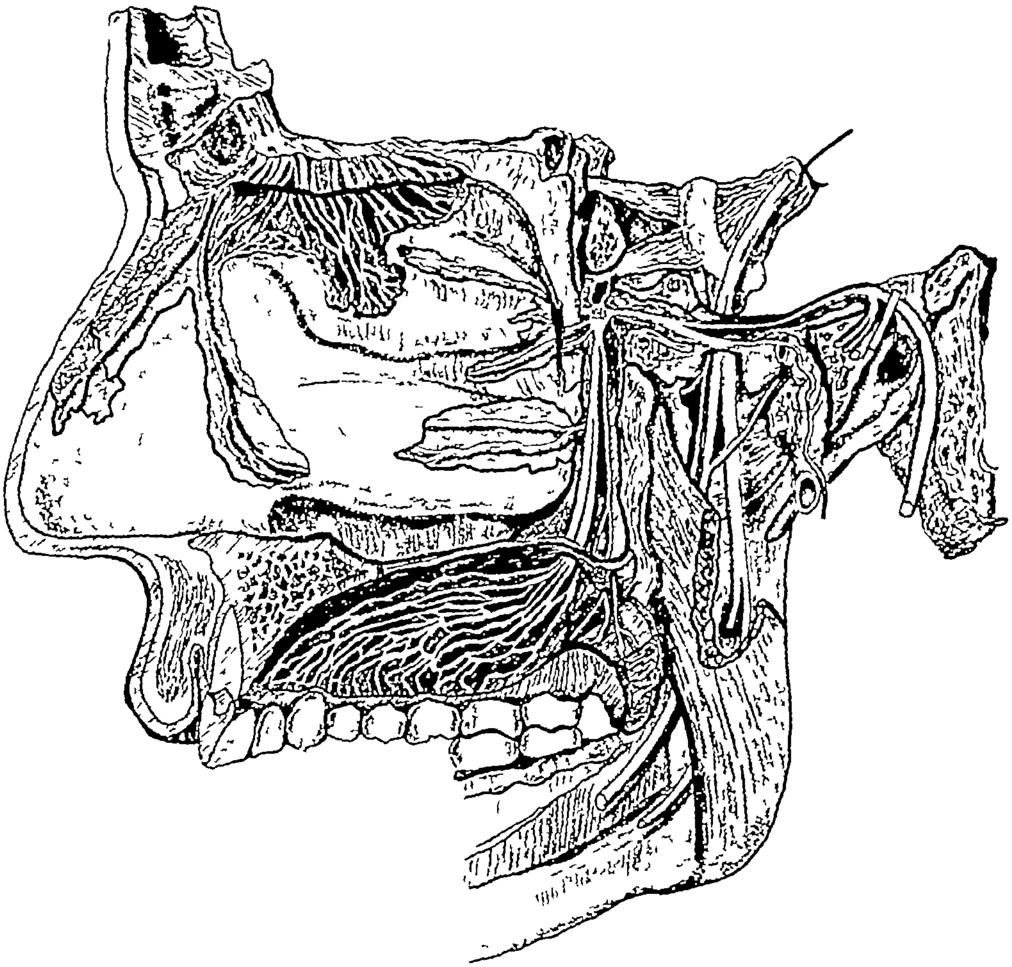

Fig 3—Shows the posterior palatine the posterior palatine foramen and the mandibular branch (From Toldt)

tive nerve, chromatolysis can not be attributed to loss of function or action. It has not yet been satisfactorily explained why, after complete division, some nerves are rapidly (by primary adhesion) restored to function, others by secondary regeneration are restored, while still others, either after division and after reapproximation (either immediate or remote), or after "pressure paralysis" without division, never regain function, still these facts exist clinically, and we must accept them in our empirical treatment of diseased, divided and contused nerves, as well as to hope that chemical substances may permanently interrupt conduction from the periphery to the center and *vice versa*. It is on this clinical basis that we are justified in hoping the trunk injections may produce more lasting inability of transmission of impulse than neurotomy or neurectomy. From Goltz's experiments it is fair to assume that bodily pain can be of central nerve origin and this is supported by irritative lesions of the thalamus (Schafer).

[18] Philadelphia Medical Journal October 1902

[19] The Healing of Nerves, Macmillan & Co 1901

[20] Neurologisches Centralblatt 190[illegible]

Last year[21] I made a preliminary report of a case operated on June 8, 1903, with the technic which has been followed, practically the same, in all subsequent cases except that I am using a 2 per cent. solution of osmic acid, where formerly I used a 1½ per cent. solution. The case reported at that time has continued free from pain up to date. In that communication I have the results of Sir William Bennett's cases as published in the London *Lancet*, Nov. 4, 1899. I have now the pleasure of reporting his more extended experience with results down to Jan. 22, 1904, as given in a personal letter, for which I express my sincere appreciation. It is as follows:

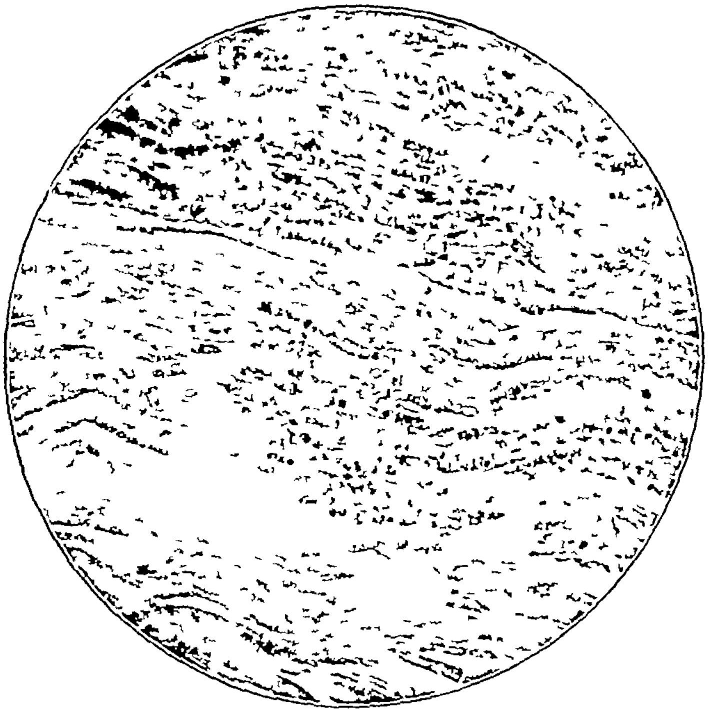

Fig. 4.—Shows a section of the nerve trunk with osmic acid discoloration and granulation condition of axis cylinder.

Results of first 20 consecutive cases operated on.

First case treated July, 1897.

2 patients remained altogether well at the end of 4 years.
2 patients remained altogether well at the end of 3 years.
3 patients remained altogether well at the end of 2 years.
2 patients remained altogether well at the end of 1 year.

Two cases may be regarded as failures, i. e., the relief was only temporary (3 months and six months). Two patients died without recurrence (1 in 9 months and 1 in 6 months) from causes unconnected with the condition for which the treatment was adopted. Six were lost sight of within 9 months after the operation.

In the other cases operated on, the time which has elapsed since the treatment is not sufficient to justify any conclusion.

In 3 of the successful cases recurrence of pain occurred: 1 at the end of 6 months, 1 at the end of 8 months, 1 at the end of 12 months.

The symptoms subsided in one of these cases after a second injection, and no further trouble had arisen when the patient was last heard from.

EXPERIMENTS.

In order to determine, if possible, the *modus operandi* of cure I have made the following experiments:

Dog No. 35.—Large size, male. Operated on Aug. 14, 1903. Osmic acid solution 1.5 per cent., freshly prepared, injected into trunks of both brachial plexuses, 5 nerve trunks were injected on each side and both supraorbital nerves. Incisions closed with subcutaneous catgut sutures.

August 18.—Extensor muscles of both fore legs paralyzed. Dog walks with paws doubled under legs. Paralysis appeared on second day and was complete on the third.

August 25.—Paralysis continues as on 18th.

September 11, 1903.—Paralysis has continued. Anterior surfaces of fore feet ulcerated from pressure of the flexed paws in attempt to walk. Dog killed with chloroform, and specimens from supraorbital nerves and brachial plexuses secured for microscopic examination. No gross changes except at points of injection where tissues were blackened.

Dog No. 37.—Small, male. Operated on Aug. 14, 1903. Osmic acid injections in trunks of both brachial plexuses, 3 on right side and 2 on left, and in right supraorbital nerve. Incisions closed with subcutaneous and over and over catgut sutures.

August 18.—Right foreleg paralyzed in extensor muscles as in dog No. 35. Left not paralyzed.

August 25.—Condition same as on 18th. Right axillary wound open and granulating but clean. Paralysis same.

Sept. 11, 1903.—Paralysis has continued. Ulcerations on anterior surface of fore feet (larger on right) from walking with paws flexed. Left cornea opaque with whitish secretion. Nutrition poor. Dog killed with chloroform. Brachial plexuses dissected to cord and specimens taken from following situations for microscopic examination: 1, at site of injection, 2, proximal to injection, 3, anterior nerve roots and posterior roots with ganglia, 4, sections of cord at levels of these roots. Both supraorbital nerves dissected out and following specimens taken: 1, at site of injection, 2, proximal to injection, 3, gasserian ganglia, 4, sections of pons and medulla with sensory roots and nuclei. Specimens put in Mueller's fluid. No gross lesions except at points of injection where nerves were blackened.

The microscopic findings on the slides made from the injected nerves as given by Prof. F. R. Zeit and Dr. A. A. Goldsmith of the Pathologic Department of the Northwestern University and concurred in by Professor Hill are as follows:

Stains were made both by the Weigert Pal, and also by the usual hematoxylin and eosin method. All the tissues were fixed in Mueller formalin. The Marchi method was not used in these specimens to show the degeneration of the nuclein sheath but was used in the experiments conducted for me by Dr. Dunn.

Dog No. 35.—Anterior roots and posterior ganglia of roots of left side, normal. Injected trunks of right plexus: Many of the medullary sheaths of the nerve fibers stained brownish black by the osmic acid. Anterior roots and posterior ganglia of left side normal. Injected trunks of left plexus: Many of the medullary sheaths of the nerve fibers stained brownish black with the osmic acid. Anterior root and posterior ganglion of right side normal. Injected part of the right supraorbital nerve: Some of the medullary sheaths of the nerves are stained brownish black by the osmic acid. Injected part of left supraorbital nerve, practically the same as right. Ophthalmic division of the 5th nerve proximal to injected supraorbital nerve of left side normal. Gasserian ganglion and ophthalmic division of the fifth nerve (left), normal Gasserian ganglion and part of sensory root (right), normal

---

[21] The Journal A. M. A., Aug. 2[illegible], 1903.

Dog No 37—Right gasserian *ganglion normal* Ophthalmic division of the 5th nerve and gasserian ganglion not injected (left), *normal* Pons and medulla with sensory root of 5th nerve, normal Injected trunk of brachial plexus (right) Many of the nerve fibers show their medullary sheaths stained brownish black with osmic acid Trunks proximal to injection in brachial plexus (right), normal Cord at level of brachial plexus, normal Trunks on proximal side of injection in brachial plexus (left), normal Anterior roots and posterior ganglia of brachial plexus (right), normal Injected trunks of left brachial plexus The medullary sheaths of many nerve fibers show a brownish black stain from the osmic acid Anterior roots and posterior ganglia of trunks of left brachial plexus, normal

While the motor nerves were paralyzed by the injection the microscopic report does not show that there was an ascending or descending degeneration or any change other than the local ones at the site of the injections in the nerve This is not sufficient to account for the clinical phenomena as obtained in our cases nor is it what should be found after a chemical destruction of a motor or combined nerve Still the fact remains that there was complete paralysis of the motor nerve and some trophic changes as well It shows that we are not permitted to use the osmic acid injections in neuralgias affecting the motor nerves

Additional experimental injections were made under my direction by Dr A D Dunn on four dogs to determine through a second source the pathologic changes produced by the injection of osmic acid into the nerve trunks and to check the former experimental results

Dog No 1—Injected March 3 1904 About 15 m of a 1½ per cent aqueous solution of osmic acid were injected into each of the supraorbitals and the cords of the brachial plexus The supraorbital incisions were closed with horsehair The axillary incision was closed with catgut and silkworm gut The connective tissue sheath *enclosing cords* of brachial plexus and great vessels was reunited with catgut

Complete paralysis of right upper extremity occurred immediately following injection and persisted until the dog was killed on the 13th day The right supraorbital incision healed by primary intention the left with a slight amount of suppuration The dog gnawed the stitches of the axillary wound which broke open and suppurated freely

Necropsy March 17 1904—Right supraorbital incision clean, an indurated lump to be felt beneath it The supraorbital nerve is buried in a mass of blackened tissue The nerve for about 1½ inches is blackened smaller in caliber and more or less adherent to surrounding tissues No suppuration Macroscopically no change could be observed distally or proximally to point of injection Left supraorbital some suppuration from wound There is a more extensive mass of inflammatory tissue The nerve when dissected out appeared similar to the right Brachial large suppurating subcutaneous pocket Considerable inflammatory deposit After sheath, which had been reformed by suturing fascia over nerves, was dissected off the nerves were readily obtained The inflammatory process seemed to have affected them little The nerves were completely blackened for a distance of 1¼ to 1½ inches Distally the diameter of the nerve seemed diminished Proximally no changes were apparent The gasserian and cervical spinal ganglia with corresponding part of cord were removed No gross changes were noted

Dog No 2—Small puppy Injected March 12 1904 About 15 m of a 1½ per cent aqueous solution of osmic acid were injected into each of the cords of the right brachial plexus and the right supraorbital The nerves were small and the injections made with difficulty The wounds were closed with silkworm gut and with catgut to unite fascia to form sheath over brachial plexus Complete paralysis of right anterior extremity *followed and persisted* up to necropsy The wounds healed by primary intention

Necropsy March 26, 1904—Induration present under right supraorbital, the injected nerve was dissected out of a mass of recent inflammatory tissue, no pus The nerve was very small and blackened for about 1¼ inches There was considerable blackening of the adjacent tissues Distally to, and at the point of injection, the caliber of nerve seemed diminished The left supraorbital was removed as a control Axillary wound healed, a considerable amount of inflammatory tissue lay about sheath of great vessels and nerves and in the para neurotic tissues The cords were blackened for 1½ inches with some diminution in their caliber at and distal to point of the injection No gross changes in cervical cord and ganglia or in gasserian ganglia

Dog No 3—Small puppy Injected March 12 1904 About 15 m of a 1½ per cent aqueous solution of osmic acid were injected into each of the supraorbitals and into each of the cords of the right brachial plexus The nerves were small and the injections were made with difficulty Much of the osmic acid escaped into the surrounding cellular tissues The supraorbital incisions were closed with silkworm gut The fascia over great vessels and brachial plexus was carefully reunited with catgut the skin incision closed with silkworm gut

Complete paralysis of the right foreleg occurred immediately following the injection and persisted until death on the 10th day There was a small amount of suppuration of right supraorbital wound The other wounds appeared to have healed by primary intention

Necropsy March 26, 1904—Induration present beneath both supraorbital wounds Suppuration from right, stitches in situ Inflammatory masses on both sides but greater on the right The tissues about nerves were much blackened The nerves were dissected out with considerable difficulty The nerve trunks were blackened for about 1¼ inches No changes distally The caliber of the nerve was only slightly diminished at the point of injection Axillary wound healed Stitches in situ After opening wound a small pocket of pus was discovered Amount of inflammatory reaction greater than usual, but the nerves were easily freed They were blackened for a distance of about 1½ inches No diminution in the diameter of trunks No gross changes in gasserian ganglia in cervical ganglia, or in cervical cord

This dog was also a small puppy Consequently injections were made with considerable difficulty and did not prove as satisfactory as on the first dog, which was very large and whose nerves were large, so that the osmic acid was easily retained within the sheath

Dog No 4—Injected March 30, 1904—The supraorbitals and cords of the brachial plexus were each injected with about 15 m of a 1½ per cent solution of osmic acid in water The nerves were laid bare and their trunks injected under aseptic precautions The incisions were closed with silkworm gut suture The fascia in the axilla was brought together with catgut The wounds healed by primary intention There was an immediate partial paralysis of the upper extremity on the injected side This rapidly disappeared so that there was little residual paralysis at the end of two weeks

Necropsy April 14, 1904—Supraorbital nerves are buried in a mass of inflammatory tissue The nerve trunks are completely blackened for about 1½ inches No changes are apparent proximal or distal to the point of injection No suppuration in axillary wound There is a considerable amount of inflammatory tissue Some of the trunks are blackened only superficially The osmic acid has apparently not penetrated well A trunk was selected in which the penetration seems to have been good There are no gross changes in the ganglia or cord

The following pieces were taken for microscopic examination At, distal to and proximal to the point of injection, the gasserian ganglia, cervical ganglia and parts of cervical cord.

This case differed from the others in not showing any of the slight changes that were present in the ganglia There was little or no diffusion of the Nissl bodies, and the nuclei were for the most part located centrally

It may be noted in these experiments that about 15 m of a 1½ per cent aqueous solution of osmic acid were injected into each nerve trunk, under aseptic precautions The supraorbitals and cords of the brachial plexus were selected for this purpose The nerves were subjected to as little trauma as possible, and the injections were made slowly The fascia was always reunited over the cords of the brachial plexus with cat gut, and the skin wound closed with horsehair or silkworm gut

The wounds usually healed by primary intention Complete paralysis of the leg in which the brachial plexus had been injected, occurred immediately and persisted until death The dogs were killed about the 13th day after the injection There was a considerable amount of inflammatory reaction in the tissue surrounding the nerve The supraorbital nerves were embedded in a blackened inflammatory mass from which they had to be dissected with care There was a considerable amount of inflammatory reaction about the cords of the brachial plexus, but the cords themselves lay comparatively free in the reformed connective tissue sheath The nerve trunks were more or less blackened for a distance of 1 to 2 inches In several instances the size was slightly diminished at, and distal to the point of injection No gross changes were observed in the proximal portions of the nerve trunks, in the ganglia or in the cervical cord

MICROSCOPIC FINDINGS IN INJECTED NERVE TISSUE AT DISTAL, AND PROXIMAL TO THE POINT OF INJECTION AND IN GANGLIA

Dog No I —Ganglia overheated Nissl's stain was unsatisfactory

	Right Supraorbital				Left Supraorbital				Cord of Brachial Plexus			
	At	Distal	Proximal	*Ganglia	At	Distal	Proximal	Ganglia	At	Distal	Proximal	Ganglia
Diminution in caliber	Slight				?				+	?

Staining of paraneurotic fat from injection	+				+				+ +	—		

* Immediately above point of injection † Diffusion of Nissl bodies in many cells, nuclei of many cells at periphery ‡ Slight changes as recorded in other nerve § Diffusion of Nissl's bodies quite marked, also peripheral location of nuclei

Dog No IV

	Right Supraorbital				Left Supraorbital				Cord of Brachial Plexus			
	At	Distal	Proximal	†Ganglia	At	Distal	Proximal	‡Ganglia	At	Distal	Proximal	‡Ganglia
Inflammatory reaction					Slight							
Focal necrosis												
Derangement of fibers	Slight	—			+				Slight	Slight		
Degeneration of myelin	+ +	+ +			+	Slight			+ +	Slight		
Diminution in caliber	Slight	Slight			+							
Leucocytic infiltration	Occas'l				Slight							
Blackening due to osmic acid injection	+*				+				+			

* Fosin affects the myelin of a few fibers blackening the sheath uniformly † No marked changes ‡ No changes

Two pieces were taken at the point of injection, proximal to, and distal to the point of injections and put in Mueller's fluid, 90 parts, formalin 10 parts After one to two days, sections from each portion were washed in water for 24 hours, mounted in paraffin and stained with hematoxylin and eosin The remaining pieces were left for two weeks in Mueller's fluid, which was changed several times to get rid of the formalin They were then placed in Marchi's mixture, which consists of Mueller's fluid 2 parts, 1 per cent osmic acid, 1 part, and left for six days They were then washed in water for two days and afterwards remounted in paraffin By this method any fatty degeneration occurring in the myelin sheath of the nerve fibers can be demonstrated It has been found that myelin which has been mordanted for eight days or over in Mueller's fluid or other solutions of the bichromates, loses the power of reducing osmic acid, while fat retains this property unimpaired The gasserian ganglia and the cervical ganglia connected with the exsected pieces of nerve were removed and placed in Zenker's fluid and stained with hematoxylin eosin and by Nissl's method after they were mounted in paraffin Specimens were taken from the cervical cord to be examined later if changes elsewhere should warrant it

Microscopic Examination—The most important changes were found at, and distal to the point of injection The degree of pathologic alteration varied to a considerable extent dependant on the thoroughness of the injection and whether infection had resulted For example, in one nerve that to all appearances was perfectly injected and blackened throughout, degenerative processes were found only in a limited portion At the point of injection there was always more or less staining of the paraneurotic and interstitial fat with the osmic acid There was quite marked derangement of the fibers The inflammatory reaction was always less extensive than might naturally be expected An occasional area of focal necrosis, a few foci of round cell infiltration, and here and there a leucocyte, attracted thither by the foreign substance, were all that was to be noted

Distal to the point of injection the nerve trunk in some cases seemed atrophic, but there were no interstitial changes Proximally, no changes were to be found except in the immediate vicinity of the injection At and distal to the point of injection, there was more or less extensive fatty degeneration of the myelin sheath, this varied in amount from the involvement of all the fibers to an occasional fiber Proximally the myelin was unaffected, except immediately above the limit of blackening, which was our means of defining the extent of injected area

There were no signs of inflammation in the ganglia Slight changes, similar to those one would be led to expect after nerve resection, were present The nuclei of many of the cells were located at the periphery and the stainable substance of Nissl was diffused throughout the cytoplasm

(*To be continued*)

Note—The conclusion of Dr Murphy's article next week will be followed by the discussion on the papers of Drs Sherman Frazier and Murphy

BLOOD PRESSURE AND PULSE RATE

AS INFLUENCED BY DIFFERENT POSITIONS OF THE BODY *

O Z STEPHENS, A M, M D
Department of Physiology Northwestern University Medical School
CHICAGO

HISTORY

The blood pressure in the arteries was first measured with some degree of accuracy by Stephen Hales in 1733 He ordered a mare to be tied down on her back into whose crural artery, about three inches from her belly, he inserted a brass pipe one-sixth inch in diameter To this pipe by means of another brass pipe, he fastened a glass tube 9 feet long, and of nearly the same diameter as the pipe in the artery He then untied the ligature on the crural artery, as a result of which the blood rose 8 feet 3 inches above the level of the ventricle of the heart [1]

While blood pressure can be measured in this way with some degree of accuracy, there are several objections to the method, chief among which are the following 1, Through the uncomfortable position of the animal and the consequent effect on the vasomotor nerve fibers, the pressure is likely not to be the same as it would under normal conditions, 2, the inaccuracy due to the speedy coagulation of the blood, 3, the clumsiness and inconvenience of the apparatus

Poiseuille, many years later, improved this method of Hales by substituting for the glass tube a mercurial manometer The tube connecting this manometer with the artery was filled with a solution of sodium carbonate to prevent coagulation of the blood [2]

Later, Ludwig made an improvement on Poiseuille's mercurial manometer by placing on the mercurial column a float carrying a writing style, by means of which records of the variation in pressure could be taken on revolving drums By means of the apparatus a fair degree of accuracy can be obtained, but the oscillations of the mercurial column, due to inertia, render it objectionable The mercurial manometer, however, has been used very extensively and with very valuable results

Piorry, a noted French physician, was one of the first to observe the effect of the force of gravity on the circulation, i e, the effect of the change of position on the blood pressure His observations, however, were clinical Having been called to a patient who had lost consciousness, and who was being supported in a sitting position by his friends, he placed him in a horizontal position, after which the patient at once regained consciousness Hill has also found, through a trephine hole in the skull, that the intracranial pressure is negative in the sitting posture and positive when the head was bent down toward the knees [3]

Many other observations of the same nature have been observed clinically on the human subject and experimentally on the lower animals

Most of the work on the lower animals has been done by inserting a cannula connected with a mercurial manometer into the carotid or femoral artery, and then shifting the animal from one position to another, about a horizontal axis which passes through the point of insertion of the cannula In this way, quite accurate results have been obtained Of course the animals were invariably narcotized or anesthetized

So far as we have been able to learn the experimental observations on blood pressure in different positions of the body have been confined to the horizontal, vertical feet-down and vertical feet-up positions The same is true of the pulse rate The clinical observations have been confined to the horizontal, head-up and head-down at no particular angle

Since the advent of the sphygmomanometer, experiments have been performed on the healthy human subject in the standing, sitting and horizontal postures

The pulse rate in the human subject in different positions of the body, so far as we have been able to learn, was first studied by Guy,[4] who made observations on 100 men, averaging 27 years of age, in the standing, sitting and lying positions He found the pulse rate to be highest in the standing, lower in the sitting and lowest in the lying positions

[2] Rech sur la force du coeur aortique Thèse Paris 1828, after Hill Schäfer's Text book of Physiol 1900 vol ii

[3] Hill Journal Physiol Cambridge and London 1895 vol xviii p 15

We see, then, that the subjects of blood pressure and pulse rate in different positions of the body are not new ones, that some of the apparatus used in getting blood pressure was inaccurate, that experimental observations were on narcotized or anesthetized animals, that clinical observations on blood pressure in the different positions of the body are *confirmatory of the* experimental observations

In our work on blood pressure we have dealt with the subject in a different manner, in some respects, from our predecessors insomuch as we have chosen more positions of the body and have taken the pressure on both sides of the body in each position

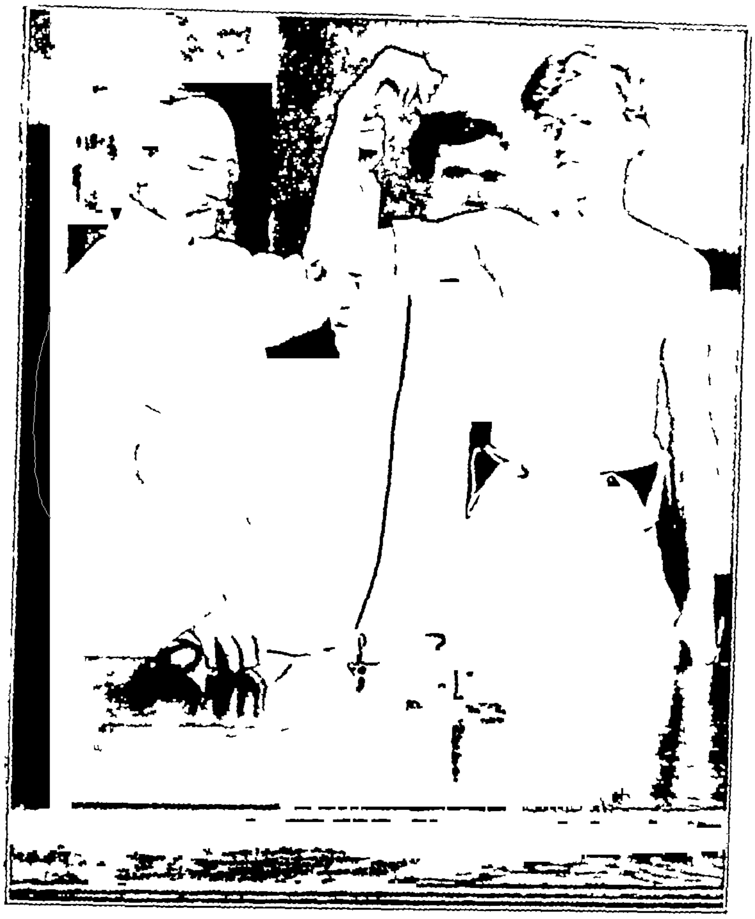

Fig 1—Standing

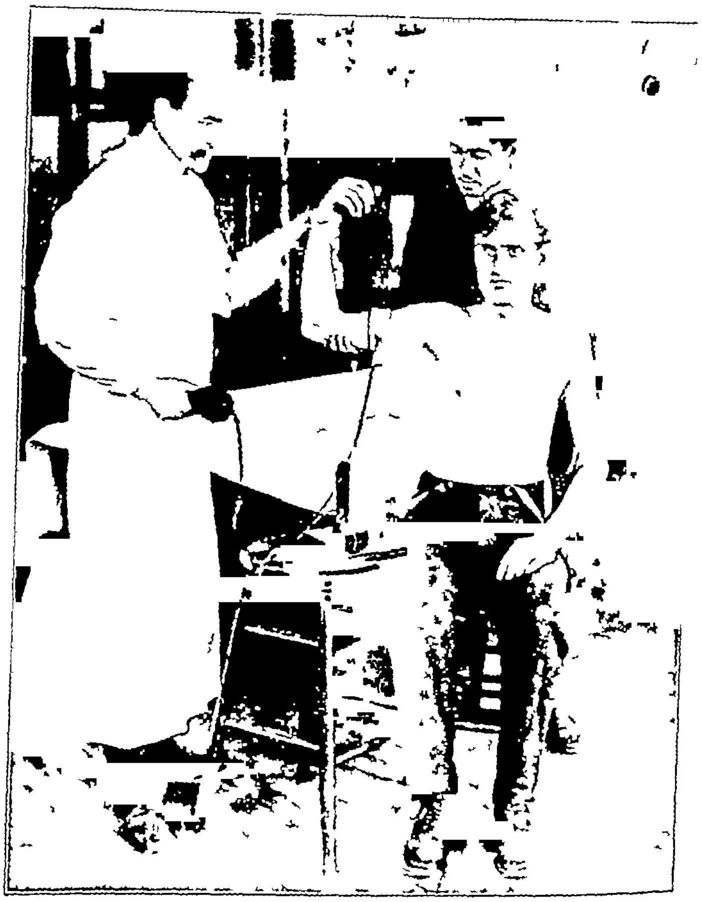

Fig 2—Sitting

METHOD

(a) *Subjects*—The subjects used in these experiments were twenty-two male medical students, with an average age of 24 years and an average height of 170 cm In one of these subjects, however, the pulse rate was not obtained, hence only twenty-one are used in making computations on pulse rate In changing from one position to another they were allowed to remain long enough in the new position for the circulatory apparatus to become adjusted to the new conditions before observations, either on blood pressure or pulse rate, were taken Every means was taken to keep them comfortable and to avoid anything which would tend to provoke excitement or muscular effort The rate of respiration was also kept normal

(b) *Apparatus*—The instrument used in taking the blood pressure was the Riva Rocci sphygmomanometer as modified by H W Cook The instrument is now so well known among physiologists that a description of it here is not demanded

(c) *Technic*—Each of the twenty-two men were taken through the following positions 1, Standing, 2 sitting, 3, supine, 4, head down at an angle of 45 degrees, 5, right lateral, 6, left lateral

The blood pressure was taken in both brachial arteries in each position by placing the band of the instrument around the upper arm midway between the elbow and shoulder

The pulse rate was also taken in each position, the count being taken through a whole minute of time

In taking the pressure in the standing position, the *patient stood erect*, the upper arm was abducted to the *horizontal* plane and the forearm flexed at right angles to the brachium and held perpendicularly, with the hand uppermost The arm was supported in this position by an assistant in order to relieve the subject of any muscular effort in sustaining the arm himself The opposite arm was allowed to hang laxly by the side

In the sitting position, the subject sat on a stool, with the thighs parallel and flexed at right angles to the axis of the body The legs were flexed at right angles to the thighs The arm in which the pressure was taken was held in the same position in relation to the body, as it was in the standing posture (the assistant supporting it) while the hand of the opposite arm lay laxly on the thigh of the same side

The subject in the supine posture lay flat on his back with legs parallel, and the arm on the opposite side to the one in which the pressure was taken lay parallel with and along side of the body The arm in which the pressure was taken was abducted to right angles with the body axis, and the forearm at right angles to the brachium and held perpendicularly Thus it is seen that the arm did not take the exact relation to the body in this position that it did in the standing and sitting postures In the latter, the brachium was so rotated that the inner aspect faced forward, while in this position the inner aspect of the brachium faced toward the feet having rotated through an arc of 90 degrees The variation in blood pressure, due to this slight difference in the relative position of the arm if there be any variation at all, would certainly be too insignificant to be taken into account

---

[4] Hill Schafer's Text book of Physiol 1900 vol ii

The subject in the head-down position was placed on a table on his back, around his ankles were placed comfortable straps, which were fastened to one end of the table The end of the table was then elevated so that the subject hung with his head down at an angle of 45 degrees The arms assumed practically the same position, in relation to the body as they did in the supine position, the forearm of the arm operated on being held perpendicularly, and the opposite arm lying along side of the body

In the right lateral position our subject lay on the right side, the head raised to the horizontal level by a pillow, the legs parallel and straight, and the left arm parallel with and on the body The right arm was extended anteriorly at right angles to the body axis the forearm flexed at right angles to the upper arm and held perpendicularly when the pressure was taken in this arm When the pressure was taken in the left arm in this posture, the right arm was allowed to assume a position most comfortable to the subject, in order to obviate any nervous influence on the circulation which might arise from the subject being uncomfortable The left arm assumed the same relation to the body as it did in the supine when the pressure was taken in it This, of course, put the forearm in a horizontal plane

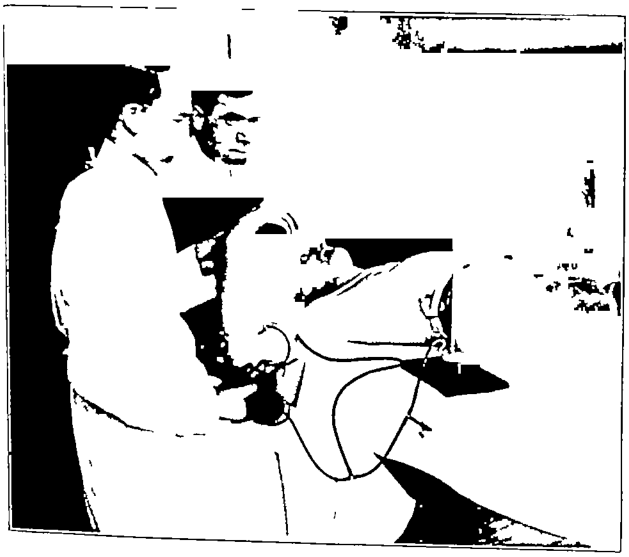

Fig 3 —Supine

The left lateral position is a repetition of the right lateral in reversed order, and need not be detailed further

RESULTS

After the pressure in each brachial was taken in a given position, the two results were averaged to obtain a mean pressure in that position The results of such observations together with the pulse rate, are shown in the following table

TABLE NO 1

No		Standing	Sitting	Supine	Head down	Right Lateral	Left Lat
1	Right arm	134	142	174	185	172	125
	Left arm	122	132	150	174	124	163

	Left arm	156	161	178	218	134	198
	Pulse rate	92	84	74	76	77	75
19	Right arm	154	151	180	198	180	127
	Left arm	151	150	169	183	112	180
	Pulse rate	82	83	78	62	71	66
20	Right arm	122	119	142	153	159	111
	Left arm	119	113	127	158	98	155
	Pulse rate	76	75	59	58	63	62
21	Right arm	127	124	159	162	143	96
	Left arm	133	127	133	161	111	157
	Pulse rate	77	72	62	58	63	66
22	Right arm	132	118	16	185	157	106
	Left arm	141	129	159	189	128	165
	Pulse rate	67	65	55	59	61	60

In summarizing the above data, we used the Hall-Quetelet method This method uses the median value, instead of the average or arithmetical mean The data collected from each individual are recorded on a card The cards from the several individuals are grouped as desired We grouped our cards according to the pulse rate and blood pressure in each arm in the different positions of the body For illustration, let us take the blood pressure in the right arm in the standing position, and let us take all those cards showing a blood pressure of 105-110 mm Hg, inclusive, and place them in one group, and all those showing a pressure of 110-115 mm Hg in another group, etc, till we have all the twenty-two cards placed in groups, the difference between the minimal values of which is 5 mm Hg pressure We shall then have the following table

TABLE No 2.

Blood pressure	105+	110+	115+	120+	125+	130+	135+	140+	145+	150+	155+	160+
No of observations	1	2	1	2	3	6	1	1	1	3	0	1

In adding the number of observations shown in the table, we get a total of 22, which corresponds to the number of subjects in whom the pressure was taken

---

5 The Journal A M A Dec. 21 1901

The next step is to find the median value, which Dr Hall defines thus "The median value is that value which is so located in the whole series of observations of a single measurement of a single group that there are as many above it as below it, i e, that the number of values which it exceeds is equal to the number of values which exceed it" Since the number of observations is 22, the median value, therefore, will have on one side of it 11 values, which are less, and on the other side 11 values which are greater than itself We must, then, find the eleventh value In counting from left to right, we find that the eleventh value lies in the group 130 mm Hg, and is the second from the minimal value and fourth from the maximal value of this group The median value, therefore lies in this group, which may be called the median group We know, then, that it must be between 130 mm Hg, the minimal value of the group, and 135 mm Hg, the minimal value of the next higher group Now, according to the biologic laws, the six values in this median group will be practically evenly distributed throughout the 5 mm Hg pressure between its minimal value and the minimal of the next higher group Hence the second value from the left must be 130 mm Hg pressure, plus 2/6 of 5 mm Hg pressure, which equals 131 6 mm Hg, the pressure for the right arm in the standing position

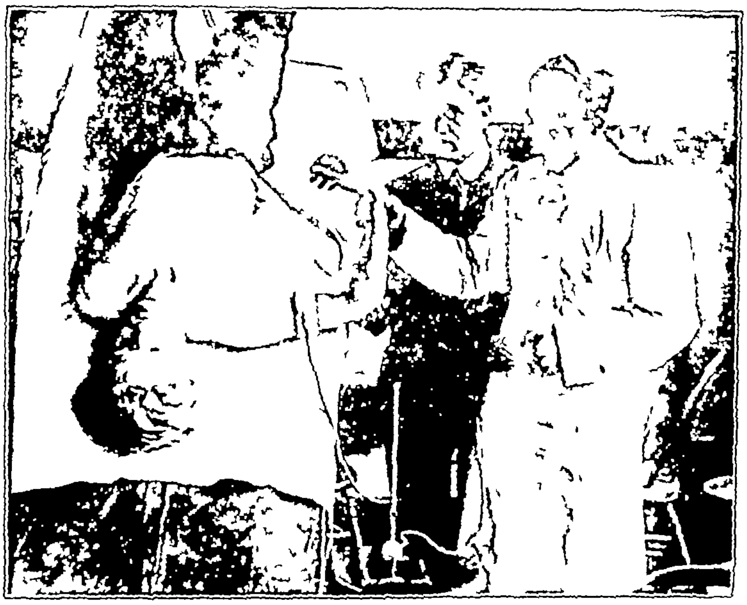

Fig 4 —Head down

Dr Hall has also reduced this process to a mathematical formula thus

Let n equal total number of observations m equal the number of observations in the median group l equal the sum of observations to the left of median group, r equal the sum to the right, a equal the minimum value of the median group, d equal the arithmetrical difference between the minimum values of the groups and M equal the median value to be determined

Then

$$M=a+[d(n-2-l)-m]$$

$$M=a+\frac{d\left(\frac{n}{2}+2-1\right)}{m}$$

$$M=130+\frac{5\left(\frac{22}{2}-9\right)}{6}=131\ 6 \text{ mm Hg pressure by substituting the values of the letters in the above cases}$$

In taking the arithmetical mean, however, we get a pressure of 132 2 mm Hg In observing the table, we see that we have one observation of quite high pressure This slight increase of the average over the median value is doubtless due to this one observation

In a large number of observations the dwarf values are likely to balance the giant values, in which case the arithmetical mean is an accurate though time-consuming method of evaluating data In a small number of observations, however, one extreme is more certain to overbalance the other, and in this case the Hall Quetelet method is the only accurate one It is also accurate in handling large numbers and is much simpler and more easily applied than the old method

Our data pertaining to the pulse rate and blood pressure in both brachial arteries, in the different positions enumerated above, were handled in this manner, the summary of the results of this evaluation being given in the following table

Table No 3

	Standing	Sitting	Supine	Head down	Rt Lat	Lt Lat

Average	130 8	131 7	125 4	165 6	134 5	133
Left arm	130	130	118 3	165	114	156
Pulse rate	86	82	65 7	65 8	68 1	69 1

DISCUSSION OF EFFECTS ON BLOOD PRESSURE

In scanning this table, it is seen that the average blood pressure in the two arms increases in the standing, sitting, supine and head-down positions, respectively, while the pulse rate decreases It has been considered that the blood pressure varies as the heart rate, times the heart strength times the resistance

Expressed in terms of a formula, we have P varies as Hr × Hs × R, where P equals blood pressure, Hr, the heart rate, Hs the heart strength, and R the resistance

This resistance may be due to arterial causes—arterial resistance, it may be due to the capillaries—capillary resistance, it may be due to contractions of the arterioles—peripheral resistance, it may be due to venous causes—venous resistance, or it may be due to the effect of gravity on the circulation—hydrostatic resistance

Now, it remains to be seen whether the phenomena observed in Table 3 can be explained by means of this formula

Standing Position—We see that the average blood pressure in the standing position is lower and the pulse rate is higher than in any other position in the series Here the current meets with the least arterial and hydrostatic resistance on the arterial side of the circulation, and with the greatest hydrostatic resistance on the venous side Both of these factors tend to decrease the pressure in the upper portions of the body by tending to allow the accumulation of blood in the lower portions of the circulatory system This is partially compensated for, however, by the abdominal muscles and contraction of the arterioles in the splanchnic area[3]

Sitting Position—The average pressure in the sitting position is nearly 1 mm Hg greater than in the standing position, a difference almost so slight in itself as to be ignored But when we observe that the pulse rate in this position has decreased four beats to the minute, more importance attaches to this slight rise *in pressure*, and we begin to wonder why the pressure did not sink with the lowering of the heart rate

According to the formula, P will vary with Hr where Hs and R remain constant Therefore, if Hr decreases, P will decrease also If P does not decrease when Hr decreases, but, on the contrary, remains *constant or* increases, it is evident that the variation of Hr is counterbalanced or more than counterbalanced by the variation of either Hs or R, or both, in an opposite direction Can we account in any way for a sufficient rise in Hs or R, or both, to produce the slight rise of P against the decrease in Hr?

It will be recalled that in the sitting position the thighs were flexed at right angles to the body axis, and the legs at right angles to the thighs, that the body was sustained erect on the pelvis, and the hand of the arm not being operated on was lying relaxed on the thigh of the same side The blood, then, must take a somewhat different course in this position from what it took in the standing position, i e, it must course around two right angles in each leg—one at the inguinal region and one at the knee It also deviates slightly from a straight line at the elbow of the arm not being operated on Thus the blood in two of the largest arteries turns two right angles in each lower extremity, and one large artery turns an angle of approximately 45 degrees at the elbow The same is true of the veins in the same localities This introduces an arterial and venous resistance which did not exist in the standing position

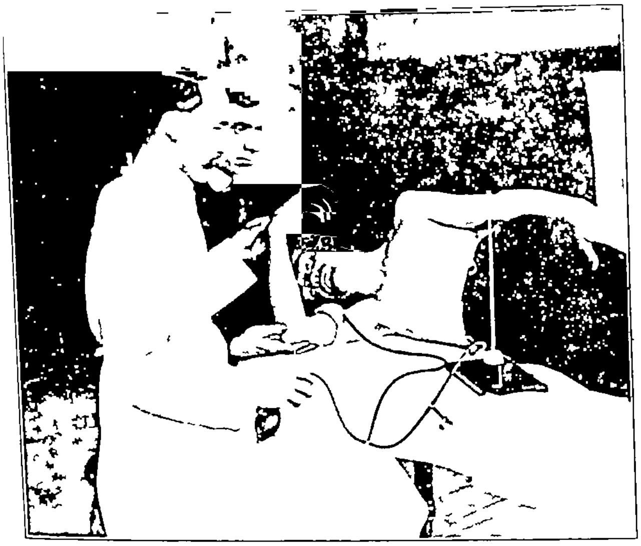

Fig 5 —Right lateral lower arm

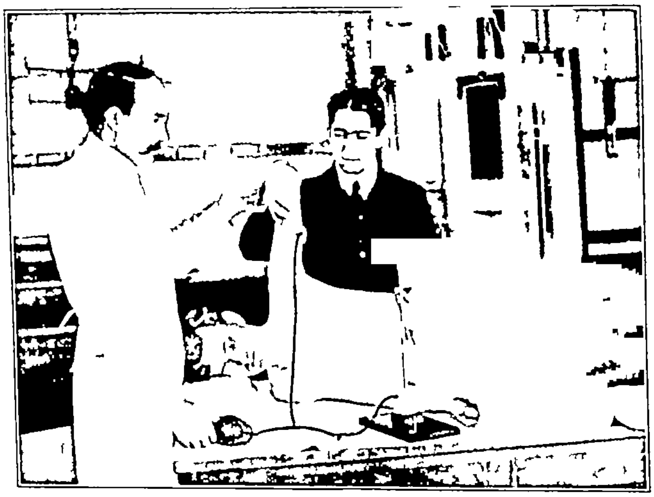

Fig 6 —Right lateral upper arm

It is possible, too, that the capillary resistance may be increased by compression of the gluteal region and upper part of the thigh by the weight of the body on them.

It has been stated that through the influence of the vasodilator nerve fibers the flow of blood to a contracting muscle is increased[6] If this be true, the flow of blood to the muscles of the lower extremities will be increased while the muscles are contracting to maintain the body in a standing position This increased flow of blood to the lower portions of the circulatory system will tend to raise the pressure here and lower it in other portions of the arterial system

The relaxation of these muscles in the sitting position, however, with practically the same tension of the abdominal muscles and the muscles of the back in maintaining the trunk erect on the pelvis, prevents the increase of flow of blood to the lower extremities, which results in higher pressure in the rest of the arterial system, i e, the peripheral or arteriolar resistance is increased in this position

The force of gravity also plays an important rôle In a man 6 feet high the hydrostatic pressure of a column of blood reaching from the vertex to the sole of the foot is equal to 110 mm Hg, and from the vertex to the middle of the abdomen about 50 mm Hg If this statement be true, the hydrostatic pressure in a man 5 feet 8 inches high—the average height of our 22 subjects—will be about 134 mm Hg Now, if the average distance from the bend of the femoral artery in the inguinal region to the bend of popliteal behind the knee be about 40 cm, the hydrostatic pressure in this position will not be 134 mm Hg by 31 5 mm Hg the pressure of a column of 40 cm There will be 10 cm of the column of 170 cm (5 feet 8 inches), on which gravity exerts a pressure downward on only the lower wall of the vessel This column of 40 cm of blood, meeting resistance to its downward tendency, has no effect through its own weight in the column in the leg below it as it had in the standing position, but tends to check the flow of the column above The latter, by its own weight or hydrostatic resistance, and the elastic force of the arteries must sweep this 10 cm of blood through a horizontal distance of 40 cm In overcoming this extra hydrostatic resistance, the column above must necessarily experience a rise in pressure Thus the decrease in the hydrostatic resistance due to the decrease in height of the column of blood, is reacted on by the increased pressure due to the hydrostatic resistance of the 40 cm to be moved in a horizontal plane This is true on both the arterial and venous sides of the circulatory system Whether or not these two factors balance we do not know However, to summarize, we see that we have an increase in the arterial, venous, capillary and peripheral resistances and also the hydrostatic resistance due to the horizontal column of blood We also have a decrease in the hydrostatic resistance due to a decrease in height of the blood column

Now, since we have an increase in P and decrease in Hr, it is evident that the increasing factors of R must more than counterbalance the decreasing factor, since the respiration was kept normal and all nervous stimuli avoided which would tend to increase Hs This increased pressure is shared by the coronary arteries, in consequence of which an increase of nutriment is carried to and increased tension placed on the heart muscle, both of which tend to increase the heart strength[7]

---

[6] Stewart Manual of Physiol 1900 p 153

[7] Roy and Adami Philosophical Trans of the Royal Society 1892 vol clxxxiii B pp 90 262

It is clear, then, that the total increase in P is not due alone to the increased resistance, but is brought about partially by the increase in the heart strength This increase of the heart strength, however, results from the increased pressure due to the increased resistance Just what proportion of the total increase in P is due to the increase in R, and what proportion is due to the increase in Hs, we do not know We conclude, therefore, that the increased blood pressure in the brachials in the sitting position over that in the standing position is due to an increase in both the resistance and the heart strength

Supine—In referring to Table 3, the median pressure in the supine position is seen to be 150 1 mm Hg, a distinct rise over that in the two previous positions We see also, that the pulse rate has decreased to 68 7 beats per minute a distinct decrease below that in the two previous positions Therefore, since P is higher and Hr lower than in the two other positions, it is clear that Hs or R, or both, have made a greater increase

Hill of London has shown that, when the body of one of the lower animals takes the vertical feet-down position, the blood pressure falls in the carotids and at the same time rises in the femorals When the body resumes the horizontal position the pressure increases in the carotids and decreases in the femorals, as compared with what it was at first When the animal is placed in the vertical feet-up position, the pressure still further rises in the carotids and falls in the femorals These phenomena he attributed to the hydrostatic pressure of the blood Again, if the phrenic nerves be divided when the animal is in the vertical feet-down position, the pressure will still further fall in the carotids and rise in the femorals Furthermore if a crucial incision be made in the abdominal walls the pressure falls still further in the carotids and rises in the femorals These phenomena he attests point to a compensatory apparatus in the splanchnic area and the abdominal walls, since compression of the latter will cause the pressure to rise in the carotids and fall in the femorals This compensatory apparatus he thinks becomes more nearly complete in animals that assume more nearly the vertical position as their natural posture, therefore, more nearly complete in man [3]

The clinical experience of Piorry, cited above, and of many others also shows the effect of gravity on the circulation in the supine position When the subject is placed on his back the blood which previously tended to gravitate to a plane below the heart, especially into the spacious venous system of the splanchnic area, now tends to become more equally distributed throughout the circulatory system, since this system has taken a horizontal position This tends to increase the hydrostatic resistance in the plane of the heart and above it, through an increased flow of blood to these regions and to lower it in the planes below through a correspondingly decreased flow to those regions

At the same time, the hydrostatic resistance is further increased by the blood in the arterial system having to be moved along a horizontal plane at right angles to the force of gravity

It is decreased, however, in the lower portions of the venous system by a force equivalent to the difference between that required to raise the return circulation to the level of the heart, and that required to move it through a horizontal plane throughout the venous system It is increased, however, in the upper portions of this system through the general tendency of the blood to become equally distributed throughout the circulatory system

The increased hydrostatic resistance in the circulatory system tends to strengthen the heart beat by increasing the nutriment to and the tension on the heart muscle This increased force of the heart "may more than counterbalance the increase in the resistance to the contractions of the left ventricle which that rise introduces, so that the ventricle may contract more completely than it did before the pressure was raised"[8]

It may be possible that the capillary resistance is slightly increased in this position by the weight of the body on the tissues of the back, this is evidently small, as the body rests largely on bony prominences, such as the sacrum shoulder blades, etc, leaving the large muscular areas of the back practically free from pressure

We see, then, that there is an increase in the hydrostatic resistance in the arterial system and upper portions of the venous system, that because of this increase of hydrostatic resistance the heart's action is strengthened that there is a possible slight increase in the capillary resistance, that there is a decrease in hydrostatic resistance in the lower portions of the venous system

Now, since P has increased, we are forced to conclude that the increase in Hs and R more than counterbalances the decrease in R in the lower venous system Furthermore, that the ultimate factor in bringing about the increase in P in this position is the hydrostatic resistance

Head-Down Position—Referring again to Table 3, it is observed that the blood pressure in the head-down position has made a leap of over 15 mm Hg above what it was in the supine, being now 165 6 mm Hg It will also be noticed that the heart rate has been lowered almost three beats per minute, the rate now being 65 8 Now since the pressure is the greatest and the heart rate is the lowest in this position, it is evident that the heart strength or the resistance, or both have experienced the greatest increase

Since the man is on an inclined plane with the head downward, it is clear that the blood will tend to course toward the head through the influence of gravity This produces an increased hydrostatic resistance in the upper portions of the circulatory system, which is greater than it was in the supine since gravity acts on an angle of 45 degrees with the course of the blood, instead of 90 degrees It is also greater than in the standing and sitting postures, since in the latter gravity acts in a straight line with the blood stream and tends to pull it to the opposite extreme of the circulatory system

The hydrostatic resistance in this position is equivalent to that of a column of blood extending perpendicularly between the plane of the feet and that of the brachial artery a distance of about 99 cm, with a pressure of about 78 mm Hg

According to Hill [3] the increased hydrostatic pressure in the carotids in the vertical head-down position is partially compensated for by a decrease in the resistance in the splanchnic area, brought about through the vasodilator mechanism but this compensation is far from complete

The same may be said in regard to the capillary resistance here as was said in case of the supine if there be an increase it must be slight

The hydrostatic pressure, being greater in the upper portion of the circulatory system than it was in the pre vious postures, will necessarily be shared to a greater extent by the coronary arteries, in consequence of which there will be a greater increase of nutriment to the heart muscle The tension on the heart will also be greater We conclude, therefore, that the strength of the heart is greatest in this position

---

[8] Roy and Adami Philosophical Trans of the Royal Society, 1892 vol clxxxiii B p 269

Lateral Positions—In Table 3 it will be seen that the pressure in the right lateral position is 134 5 mm Hg, and the pulse rate is 68 1 beats per minute in the left lateral the pressure is 133 mm Hg, and the pulse rate 69 1 per minute Here the same general law holds good—that the pulse rate decreases as the pressure increases But we notice that the pulse rate approximates that in the head-down position, while the blood pressure approaches that in the standing and sitting postures, i e, the pressure is lower compared with the pulse rate than in the other lying positions

Now since the pulse rate is much lower and the blood pressure slightly higher in these positions than in the standing and sitting positions it is manifest that both the heart strength and resistance, or either one of them must be increased to a greater extent than in the latter For convenience we shall take the average pressure and pulse rate in these positions in comparing them with the others, and later take the two separately in comparing them with each other The following table will then be useful

Table No 4 —Lateral Positions

	Right Arm	Left Arm	Average	Lower Arm	Upper Arm
Blood Pressure	134 5	133	133 8	155 5	112
Pulse Rate	68 1	69 1	68 6		

This table shows the average blood pressure in these positions to be 133 8 mm Hg and the average pulse rate 68 6 beats per minute By comparing these figures with those in Table 3 we see the pulse rate is nearly the same as in the supine and but slightly higher than in the head-down positions, while the pressure is much lower That means that the heart strength, the resistance or both, have decreased

How can we account for these phenomena? In the first place, how can we account for the slight increase in the pressure over the great fall in the heart rate from what it was in the standing and sitting positions? In the latter a comparatively small amount of blood was moved along a horizontal plane by the heart force, thus overcoming the hydrostatic resistance due to gravity acting at right angles to the blood current, while in the lateral positions the blood moves nearly horizontally through the entire circulatory system

Here also, the blood tends to become more equally distributed throughout the circulatory system This results in a lowered hydrostatic resistance in the lower portions of the body with a corresponding increase in the upper portions

In this position it will be recalled that the lower arm was extended anteriorly at right angles to the body axis Instead of the blood passing from the subclavian artery through the brachial in a straight line to the elbow it deviates 90° from this course and passes directly forward This offers a greater resistance to the blood current above, and at the same time tends to lessen the pressure in the radial below it We conclude therefore that because of this variation the systemic pressure is somewhat higher than is recorded in the above table This is a greater arterial resistance than we had in the standing and less than in the sitting positions In the upper arm the forearm was horizontal instead of perpendicular, as it was in the other positions, while the brachium was perpendicular instead of horizontal Hence these two differences balance Because of the increased resistance the heart force is also increased in the same manner as has been given above

We see, then, that the hydrostatic resistance is greater in the planes of the heart and above it, in these positions, than in the standing and sitting positions, that the arterial resistance is slightly greater than in the standing, but less than in the sitting position, that the heart strength is increased because of the increased resistance Now, since P is slightly higher and Hr much lower, Hs and R, one or both, must be much increased

Now, why is the pressure lower than, and the heart rate nearly the same as, it was in the supine? In the latter the circulatory system lies practically in a horizontal plane In the lateral positions it is "on edge," as it were, and beside the upper portion is slightly higher than the lower, since the distance from the central axis of the body to the point of the shoulder is somewhat greater than it is from the same axis to the most distant point of the crest of the ilium or great trochanter This gives a slightly inclined plane down which the blood tends to gravitate toward the feet, thus raising the pressure below the heart and lessening it above, as compared with what it would be in the supine position The resistance, therefore being less, the heart strength will be less because of lessened nutrition to, and tension on, the heart muscle The decrease in P, then, must be due to a decrease in Hs and R

The same things are true in the head-down position as in the supine, but in a more marked degree Here, however, Hs has decreased to a greater degree, hence, we conclude that P has decreased as a result of the decrease in Hr, Hs and R

Now, Table 4 shows that the average pressure is 1 5 mm Hg greater and the pulse rate a half beat less in the right than in the left lateral position How may this slight rise or pressure be explained?

The aorta passes from the left ventricle upward and slightly forward and to the right It then curves backward, upward and to the left Therefore in the right lateral position the heart lifts the greater portion of blood against the force of gravity to the perpendicular distance between the planes of the mouth of the ascending and the beginning of the descending aorta, respectively It also turns this blood through a semicircle in its course through the arch In the left lateral this resistance is absent The force of gravity alone would be sufficient to take the blood around the arch of the aorta after it reaches the top of the ascending portion This increased resistance in the right lateral in turn produces a greater heart strength It is clear, then, that the increase in P is due to an increase in Hs and R

DISCUSSION OF EFFECTS ON PULSE RATE

‘The mere fact that the centripetal fibers which call the vagus into play by reflex action come chiefly from the heart itself, shows that one part, and a very important part, of the vagus function is to reduce the work done by the heart in the interest of the heart itself We conclude, then, that the vagus acts as a protecting nerve to the heart, reducing the work thrown on that organ when, from fatigue or other causes, such relief is required by it The fact, however, that there exists centripetal fibers which call the vagus center into activity in such nerves as the sciatic and splanchnic, shows that the vagus mechanism may be called on to act in the interests of other parts of the body whose circulation requires to be diminished We conclude, therefore, that the vagus may be used by other parts of the body to diminish the blood pressure and the output of the heart, and thereby reduce the circulation

'Among the organs whose protection against over-congestion is of the greatest importance, it need hardly be said that the central nervous system takes the foremost place It is well known that if the intracranial pressure be raised artificially powerful excitation of the vagus center is produced Vagus action also results from rise in the blood pressure in the systemic arteries, and the excitation thus produced can be shown to be due to the high pressure within the vessels of the central nervous system and not to any direct effect of the rise of pressure on the heart We must, therefore, look on the vagus mechanism as a means by which the central nervous system gains protection against too great congestion

"The dependence on the blood pressure of the degree of vagus action, and the readiness with which the vagus center in the medulla is called into play by a rise of the intracranial pressure, seem to us to indicate that the mechanism in question is especially employed in the interests of the central nervous system as well as the heart itself"[7]

Now, if it be true that the vagus acts as a protecting nerve both to the heart itself and the central nervous system, it is clear that the reduced heart rate in the various positions of the body in the order named is in response to the action of the vagus in endeavoring to protect the heart and central nervous system against the increasing pressure

SUMMARY

1 The blood pressure increases in the brachials from the standing to the head-down positions, inclusively, in the following order Standing, sitting, left lateral, right lateral, supine and head-down

2 The greater the hydrostatic resistance in the upper portions of the circulatory system the greater the increase in pressure where the nervous and respiratory systems are kept normal

3 An increase of resistance is accompanied by an increase in heart strength, the strength of the heart, therefore, will increase in the different positions in the following order Standing, sitting, left lateral, right lateral, supine and head-down

4 The pulse rate decreases in the same order that the blood pressure increases

5 The decrease in the pulse rate is a conservative act on the part of nature to protect the heart itself and the central nervous system

DISCUSSION

Dr. H G Brainerd, Los Angeles, Cal —Are these data altogether from pressure in the arm, or are they taken in any other way? Can they be taken in the temporal region or elsewhere? The Riva Rocci apparatus, as I have it, is not adapted to use in the temporal region I have been very anxious to find what the temporal blood pressure is and how it compares with the pressure in the arms Would it not be necessary to use an air pad?

Dr Winfield S Hall, Chicago—The Riva Rocci apparatus, as it is furnished to us by the medical instrument houses, is not adapted to taking any measurements except those on the arms or legs A very easy adaptation can be made for taking the pressure in the temporal artery One has only to put a band around the head, insert an inflatable bulb between the band and the temporal artery, and inflate the bulb sufficiently to cut off the temporal pulse Having thus a method of determining the pressure in the temporal artery, we could, at the same time, take the pressure in the brachial artery, and also perhaps that in the popliteal artery With these three observations taken simultaneously one could compare not only the three different pressures, but could also get an idea of the average arterial pressure

TREATMENT OF FRACTURES OF THE PATELLA BY LATERAL SUTURES *

JOSEPH A BLAKE, M D

NEW YORK

The question as to the operative versus the mechanical treatment of fracture of the patella has been ably discussed in a number of papers in the last few years Some of these have been read before this Association

I do not intend to reopen this discussion, inasmuch as my contribution deals only with a detail in the technic of the open operation, yet it is only fair that, in order that I may not be misunderstood, I should state my position in the matter, the more so, since the principle of my technic is closely linked with the reasons for my views in regard to the treatment in general

Fractures of the patella are divisible into two classes —those caused by direct and those caused by indirect violence Or, as von Mikulicz[1] has very aptly put it, "blow" and "tear" fractures To this classification he also added another which was the result of both, or a "combination" fracture

The difference between the "blow" and the "tear" fracture is well known to all, yet the importance of its bearing on the question of treatment seems to be generally overlooked In the fracture by direct violence, usually the bone alone suffers, and although it may be comminuted, there is little separation of the fragments In the "tear" fracture, on the other hand, not only the bone but the lateral expansions of the quadriceps muscle on either side of the patella are likewise torn, and there is considerable separation of the fragments In the "combination" fracture the injury to the soft parts is similar

Great stress has been laid on the interposition of fibrous frills from the torn aponeurotic structures covering the patella by the advocates of the open operation This interposition does not occur in the "blow" fractures, because these structures are not frilled

The fractures by direct violence or blow fractures, then, do not offer indications for open operation, except for the reduction of otherwise irreducible displacements of the fragments, and in practice their treatment by mechanical methods will be found to yield excellent results On the other hand, the treatment of the "tear" fractures by mechanical means is extremely unsatisfactory These cases, unless contraindications exist, by reason of age or disease, should in my mind be operated on, particularly those to which a sound limb is a necessity

The indications for operation consist, then, not in the extent of injury to the patella itself, but to the lateral extensions of the insertion of the quadriceps extensor muscle The importance of these structures has been emphasized by von Mikulicz,[1] who termed them the "para patella ligaments" I have been accustomed to call them the lateral patella ligaments and for convenience shall adhere to that term They are strong aponeurotic structures which are directly connected with the tendon above and with the ligamentum patellæ below, and, in fact, extend its insertion laterally to the tuberosities of the tibia On their deep surfaces they are intimately blended with the capsule of the joint

---

* Read at the Fifty fifth Annual Session of the American Medical Association in the Section on Surgery and Anatomy, and approved for publication by the Executive Committee Drs DeForest Willard Charles A Powers and J E Moore

[1] J von Mikulicz British Med Jour, Dec 13, 1902 p 1828

In direct fractures of the patella, the lateral patella ligaments remaining intact, considerable power of extension is present, although the patient may not exercise it on account of pain In such cases when voluntary trials at extension are made or when the knee is passively flexed little separation of the fragments will result The function of the ligaments is so important that when these structures are torn as in the "tear" fractures, no operation based on the suture of the patella alone is correct The lateral patella ligaments should be sutured as well In fact, I have gone so far as to rely on suture of the lateral patella ligaments alone in the treatment of "tear" fractures, only employing enough other sutures of fine catgut to coapt the remaining fibrous tissues

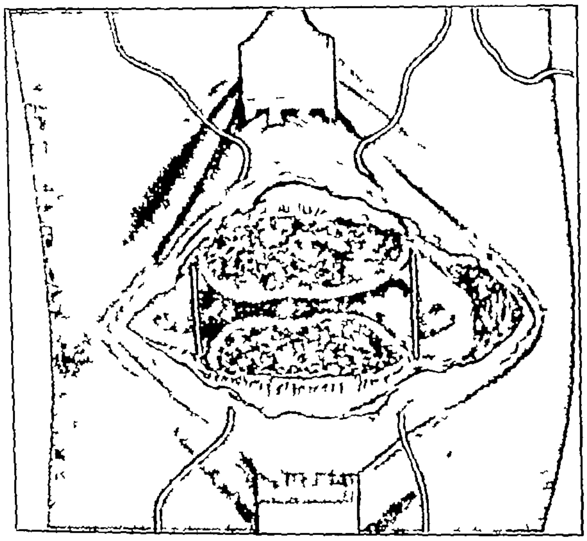

Fig 1—Showing the method of introducing the sutures close to the sides of the fragments and in front of the synovia

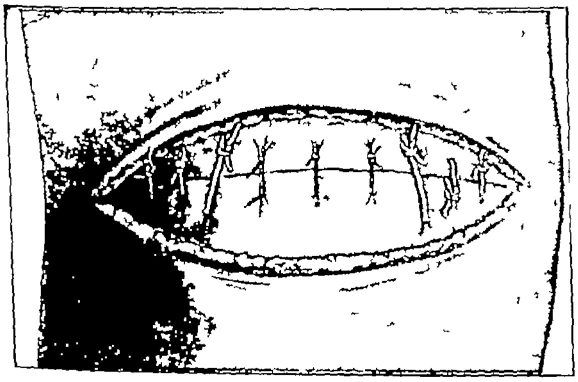

Fig 2—Main sutures tied with others to repair the extensions of the tears in the lateral patella ligaments and coapt the tissues in front of the patella

OPERATION

The steps of the operation are as follows A curved transverse incision, one centimeter below the line of fracture and long enough to sufficiently expose the tears in the lateral patella ligaments, is made The fringes of the aponeurotic tissues, which are usually found closely applied to the surfaces of the fracture are separated and trimmed off with scissors, and the blood clots washed out of the joint with a stream of sterile salt solution All these manipulations are performed with instruments, not even the gloved fingers touch the tissues Irritation of the synovia by sponging is abstained from

A suture of strong chromicized catgut, No 4 preferably, or kangaroo tendon is then introduced in the lateral patella ligament on each side of the patella in the following manner A strong, full-curved Hagedorn needle is inserted one centimeter from the line of fracture and as close to one of the fragments as is possible and brought out in the line of the tear just in front of the synovia, again introduced at a similar point at the margin of the opposite torn surface and hugging the other fragment it emerges one centimeter from the line of fracture on the anterior aspect of the lateral ligament (Fig 1) The sutures are introduced on both sides of the patella before tying It is very important that the sutures should be introduced as closely as possible to the fragments The sutures are now tightened and tied simultaneously, and the coaptation of fragments will be found to be so exact (Fig 2) that the slightest movement on one another in any direction is absolutely impossible on account of the interlocking of the slight irregularities of the surfaces

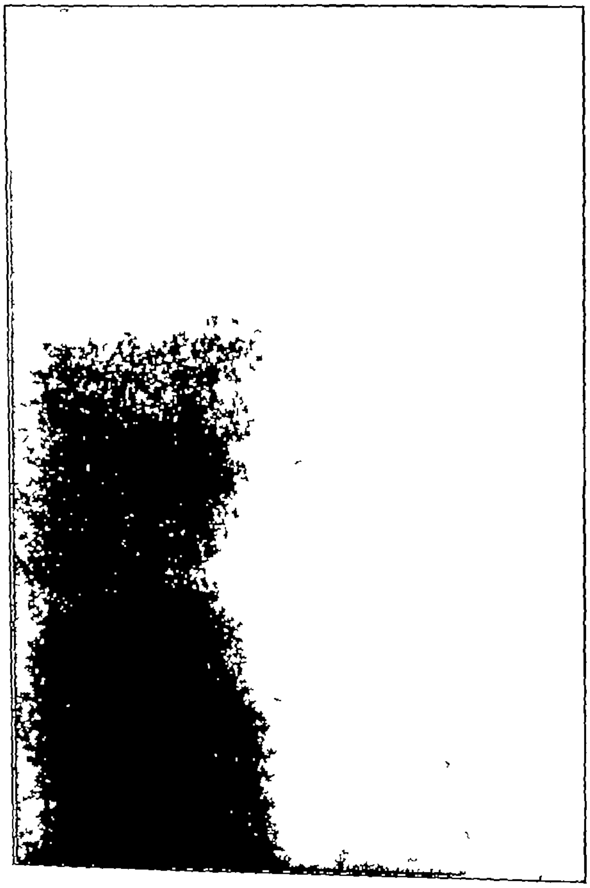

Fig 3—E W female age 35 years. Refracture of right patella X ray four weeks after second operation.

The coaptation will be good even if the fragments are comminuted, provided the sutures grasp the tissues beyond the fragments

The reason for the accurate coaptation lies in the fact that the stress of the sutures is exerted at right angles to the centers of the surfaces of the fracture, a feature which is not accomplished by any other method of suture with the exception of the purse string

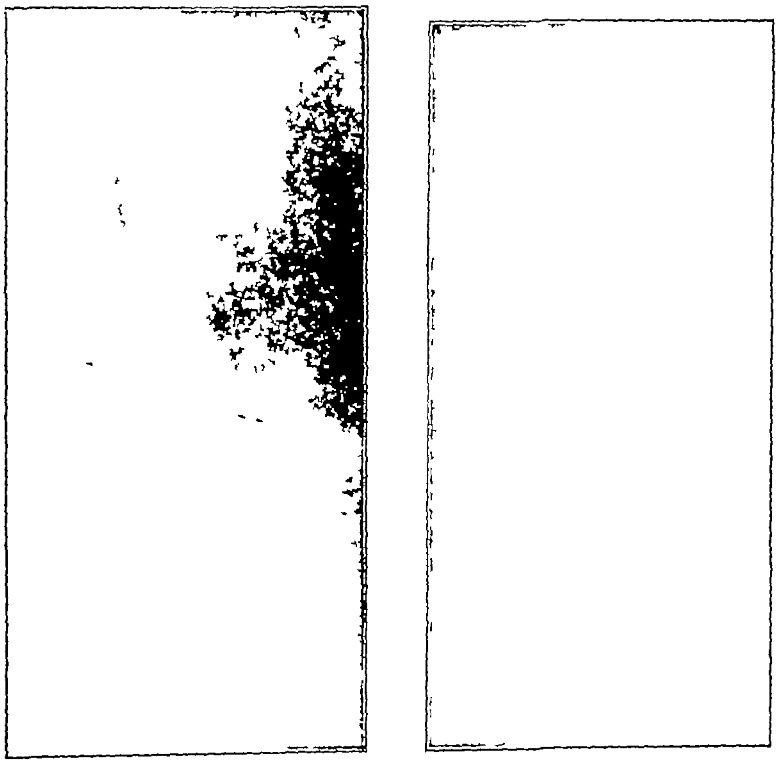
One or two additional chromicized sutures of somewhat smaller size are used to repair the extensions of the rents in the lateral ligaments, and the aponeurotic tissues in front of the patella are united with a few fine catgut stitches, the point being not to introduce any more sutures that are not readily absorbable than are absolutely necessary (Fig 2)

The cutaneous wound is closed with silkworm gut without drainage

The whole procedure should not occupy more than fifteen minutes

The advantages of the method are its simplicity and ease, the avoidance of prolonged manipulation and traumatism, which is unavoidable when the fragments are bored for sutures the exertion of the lines of the restraining force in the most efficient direction the absolute coaptation, use of absorbable sutures and its rapidity

In regard to the last point, I think that it is generally conceded that with the present perfection of aseptic technic as regards instruments and gloves, infection occurs almost in direct proportion to the length of the operation and the consequent traumatism of the tissues



(Left knee) (Right knee)

Fig 4 —F B male age 19 Fracture left patella junction lower one third and upper two-thirds Tear later ligaments ¾ inch on each side X ray 2½ years after operation Union and function perfect

The after-treatment is the usual one A molded plaster splint is put on which is removed daily for massage after the fifteenth to the twentieth day

In regard to the time for operation I consider it is well to operate as soon as is convenient after the injury I do not wait for the effusion to subside In fact, I think it a distinct disadvantage to delay opera- over four or five days since after that time the tis- begin to heal in abnormal relationship and the ulty in properly coapting them is thereby increased by then the fibrous fringes become attached to the faces of the fracture and fresh hemorrhage is pro- oked in separating them

RESULTS

used this method exclusively for three years, ing that time have sutured by it twenty-two of the patella two of them being refractures ese cases two have been done so recently that the result as regards bony union is still undetermined In the remaining twenty, bony union was obtained There have been no infections, the wounds healing in all *per primam*

In regard to the restoration of function Some have passed from observation before the motions of the knee were absolutely free, but in all the cases that I have been able to trace, three months after operation the motions of the knee have been perfect, with one exception to be mentioned later In the earlier cases I was not so particular in instituting early massage, and some of these cases were left in splints for six weeks, consequently, the motions of the joint were limited for longer periods than would otherwise have been the case

Two patients refractured their patellæ One of these was a laborer, 39 years of age The original fracture was by indirect violence, and was accompanied by considerable separation and tearing of the lateral patella ligaments The fracture was a clean transverse break Two months after the operation while walking, he slipped on some ice and refractured it He immediately reapplied for operation At the operation the surfaces of the break were found to be as rough and sharp and bleeding as freely as when first fractured, and there was not the slightest evidence of fibrous union Furthermore there had been a considerable formation of new bone on the sides of the patella at the ends of the original line of fracture Union had been bony, but the time elapsed (two months) since the first fracture had probably not been sufficient for the new bone to become as dense as it would have later The second operation resulted in good union, but there was a great deal of thickening of the soft tissues and considerable stiffness remaining when the patient passed from observation some three months afterward

The other case was a negress, 35 years of age The original fracture was a transverse one with tilting of the lower fragment, so that its fractured surface was directed forward There was considerable separation The result of the first operation was perfect as regards union and function Seven months later she fell and refractured it At the operation I was at first unable to determine whether the fracture was at the site of the original one or not, the surfaces were so sharp and rough Finally, I noticed that the fractured margin of the articular cartilage was somewhat rounded, showing that the line of the second fracture coincided with that of the first The result of the second operation was excellent Figure 3 is from a radiograph taken thirty-five days after operation

In these cases there was no evidence at the second operation of there having been any int e with the circulation in the fragments as a re mal procedure In fact in one of them able proliferation of new bone at th tella at the points where the gre sutures was exerted In some c there was comminution of the fra a marked production of new bo of repair, thus adding consider patella This is evident in th graph (Fig 4)

In the preparation of this pa radiographs of as many of the though I heard from many of th six to come for radiographs Tn were taken and the comparison teresting, particularly in regar the bone as a result of commi

DISCUSSION

Dr John H Gibbons, Philadelphia—The improved technic added to our knowledge of the pathology of fractures of the patella have gradually increased the indications for operation on this condition One supposed contraindication to operation is age, but the excellent result I recently obtained in a man over 60, operated on ten weeks after fracture, convinces me that age alone is no longer a contraindication I showed this case at the Academy of Surgery recently and demonstrated a perfect restoration of function There is one contraindication to which we should always give consideration, and that is alcoholism Delirium tremens is a common and serious complication in fractures The incision is an important point The old straight incision should be relegated to the past and Dr Blake's curved incision extending just below the line of fracture is much to be preferred to the straight one With the straight incision you can not satisfactorily perform the operation as it is impossible to get at the lateral ligaments I use a horseshoe shaped incision for all operations on the patella and its bursæ The question of sutures should be referred to and I do not believe that wire is required for the satisfactory union of this fracture I agree with Dr Blake that the absorbable suture is the better We will get practically as good results by suturing only the tendon as by suturing the bone The avoidance of rough handling of the tissue is important as traumatism of this character is more apt to result in infection than probably any other one thing Early massage is an essential in the after treatment. We are apt to keep the limb quiet too long We can make the mistake, however, of giving massage and movements too early, as I did in one of my cases The man was out of bed at the end of two weeks The result was only some swelling and ultimately the limb was just as useful as in other cases I want to lay stress on the fact that massage is an essential part of the after treatment

Dr G T Vaughan, Washington, D C—The incision depends on the case For recent cases I believe the horseshoe or transverse incision is better, but in old cases, with a good deal of separation of the fragments, the longitudinal incision is better The transverse incision can be reinforced if necessary, but a long longitudinal incision is the better This method of uniting the lateral ligaments has been usually done in fractures of the patella. I always unite the lateral ligaments when they are lacerated I have seen cases where there was very little laceration of the ligaments, as in fractures from direct violence As to the suture, at first I thought it was almost inexcusable to put silver wire into the knee cap, but I have had good results follow the use both of kangaroo tendon and catgut I have also seen some bad results, but they were not my cases Sometimes the animal suture gives way too early, and recently I have been using silver wire on this account To get patients up early the fragments should be fastened together with silver wire, though, as a surgical principle and as a rule I do not approve of the non absorbable suture The old cases sometimes give trouble when there is a great deal of separation I would like to know the best way to get the fragments together I have used two methods, one of which was to split the tendon of the quadriceps down, cutting across on opposite sides above and below, and the other was to make an oblique cut across it and slide it down. Both of these have been followed by good results, and I have had no particular weakening of the quadriceps extensor I have had 19 cases altogether of operation for fracture of the patella In one of the earliest I used the old Barker method and got a fibrous union Bony union resulted in all the other cases I had one patient with a refracture of the patella, the fracture occurring at a different site, one third of an inch above the original fracture

Dr C O Thienhaus, Milwaukee—In April of this year I operated on a man who fractured his patella two years ago in South Africa After having been confined in the hospital at Rhodesia and having been treated by conservative non operative methods for nine weeks, he left the hospital with an apparatus without union When I saw him the distance of the fragments was about 15 cm, his leg almost useless, the condition having grown worse within the last year, and he was unable to extend his leg when it was flexed The difficulty of getting the fragments together in such cases is very often enormous and different methods of lengthening the rectus femoris muscle have been proposed Some years ago von Bergmann advised chiseling off the tuberosity of the tibia with a wide chisel Thereby the inferior fragment is made movable and later heals higher up In many cases this method alone has proven sufficient to get the fragments together, but this was not possible in my case I, therefore, combined this method with one of the methods of lengthening the rectus femoris, that is, by a Z shaped incision through the muscle After this I succeeded in getting the fragments together and wired them with three silver wires, one of which was removed four weeks after operation The result has been satisfactory, bony union was obtained He walked without the aid of a cane eight weeks after the operation There is still some stiffness in the joint which must naturally be overcome by bending the knee gradually to avoid a refracture

Dr J F Binnie, Kansas City, Mo—I do not think bony union is of very much importance Thoroughly good fibrous union between the fragments seems to give every bit as good functional results as is possible I have never yet wired the patella simply because by following a method similar to Dr Blake's and getting free exposure of the lateral ligament, I have gotten just as good results There is no use bothering with wire I would strongly advise 1 early operation before there has been time for marked changes to take place in the tissue, and 2, thorough operation and suturing of the lateral ligament I use catgut, either plain or very mildly chromicized I very much dislike strongly chromicized catgut

Dr D N Eisendrath, Chicago—I was obliged to resort to a similar method to that described by Dr Blake about one year ago in a case of fracture of the patella The operation was performed twenty four hours after the injury, and my original intention was to drill the upper and lower fragments respectively, and unite them by means of a kangaroo tendon Unfortunately, just at the moment when most needed, the drill failed to act, and I was obliged to utilize simply the periosteum covering the anterior surface of the patella in order to get a basis of support for my sutures I used one kangaroo tendon over the center of the patella, inserted in a mattress fashion, and was very careful to turn outward the edges of the periosteum at the line of fracture believing that this turning in of the periosteum, thus separating the bony edges will often prevent good union I fully indorse the point made by Dr Blake as to the necessity of inserting sutures through the aponeurosis of the quadriceps lateral to the break in the patella, because the fracture of the patella is almost invariably accompanied by a more or less severe laceration of the aponeurosis I agree that fractures of the patella should not be operated on unless the most aseptic conditions prevail The early use of massage to overcome the atrophy of the quadriceps is of the greatest importance

Dr J B Bullitt, Louisville, Ky—The phase of the subject presented by Dr Blake has not had the wide recognition that it deserves, and it seems to me that we should change the nomenclature Instead of sticking to "fracture of the patella" we should say "rupture of the lateral ligaments" of the patella The attention of the surgeon has always been directed rather to the broken bone than to the ruptured ligaments We should keep our attention confined to the latter Dr Binnie says that he does not give any attention to the fracture of the patella, and he is about right. It has been demonstrated that the patella is not essential and that a perfectly strong joint can [illegible] had without it. The separation of the fragments with non union and the resulting disability has ofttimes led to the impression that it was the non union which led to the disability, whereas it was simply the lengthening that caused the trouble I am glad to report that success in this operation has no geographical limitations south of Mason and Dixon's line just as north of it. I have operated on three patellæ in two cases and have obtained quite satisfactory results As to the time elapsing before operation, Dr Blake says that four or ally exist in combination with other materials, is it not likely, in certain conditions in which the secretions are hypoacid, that when the secretion comes to the surface of the mucous membrane, owing to its chemic combination with oxygen, there is liberated NH_3, the irritating ammonia gas? Surely the symptoms, identical with those produced by ammonia gas, in many cases justify this conclusion, and the chemic study of the secretions supports this view

Many cases of hay fever illustrate this point, although in hay fever the nasal secretions may be either hypoacid, hyperacid or neutral, or irregular

ETIOLOGY

The numerous theories as to the etiologic factor in this disease prove conclusively that as yet there has not been established a definite cause It may be that different conditions act as etiologic factors, in fact, it is *my* belief that not all cases which we call hay fever, or hyperesthetic rhinitis, are due to any one cause, or, if to any one factor, that factor must be the altered chemistry of the secretions of the individual In fact, I am persuaded, after making a series of examinations of the saliva in certain individuals afflicted with hay fever and those not so afflicted, that in some cases the causes, direct or indirect, of local irritation in the nasal mucous membrane are brought about by chemic change in the constituents of the secretions of the mucus-secreting glands Treatment based on this view is certainly most effective Sensitive areas within the nasal cavities, or irregularities in formation of the cavities themselves, are factors in some cases, yet such areas or irregularities, instead of being etiologic, are merely auxiliary factors, which render the individual more susceptible to the irritant from within

It is a well-known fact that in many cases of hay fever the irritation is not limited to the nasal mucous membrane, the conjunctival, buccal, pharyngeal and laryngeal mucous membrane, and even that of the stomach and bladder, may be markedly involved This could scarcely be explained on the basis of a reflex neurosis In such cases the mucous membrane suddenly becomes engorged, and is exceedingly sensitive, with profuse, watery, irritating discharge This comes on suddenly, often without any apparent external irritant, and at times looks very much as though there was an effort on the part of the mucous membrane to rid the system of material which had just reached a certain point of accumulation.

The question may be asked Why does hay fever come on at certain times of the year? That climatic and atmospheric conditions produce changes in function and secretion, that certain diseases are prevalent at certain times of the year, and that under certain climatic and atmospheric changes individuals are more susceptible to disease, has long been observed This may be due to some condition of the individual which renders him susceptible to disease, owing to lowered cell resistance and altered chemistry, since temperature and climatic changes do affect the chemistry of the secretions As to the effect of pollen in certain cases, is it not possible that, owing to some peculiar constituent of the secretion of the mucous gland, there is deposited in or on the nasal mucous membrane certain materials which when brought in contact with certain extraneous materials as pollen, through some chemic action produces a material which brings about the irritation and causes an attack of what is known as hay fever, or that the extraneous material merely acts as a stimulant to the mucous glands and causes a flow of mucus, which, owing to its altered chemistry, acts as an irritant?

This is exemplified in the cases in which the ammonium salts bring on an attack identical with that produced by the rag-weed pollen If the administration of the tincture of rag-weed produced immunization to hay fever, it must do it through the secretory function, and the chemistry of the secretions *would* be such as to contain no materials which, when coming in contact with the pollen of the plant, would produce any irritating substance I have seen cases illustrating this point

There is no question that the irritation is caused by some product of chemic action The question involves organic chemistry, and any one familiar with the wo , recognizes the time and labor necessary to work out such chemic formulæ I have, however, done sufficient laboratory work in the past eight years to convince me that on this basis we can relieve many cases of hay fever That the chemistry of the secretions has *to do* with the causal factor I have illustrated in a number of cases by rapidly changing the reaction of the secretion either from acid to alkaline or from alkaline to acid, or rendering it neutral, and in many instances I have been able, either partially or wholly, to cure the attack

Certain individuals will have, at any time in the year an attack which is quite similar to hay fever The individual may be sitting comfortably at home, subject to no draughts or exposure whatever, when he is suddenly seized with congestion of the nostril, followed rapidly by the thin watery discharge of a decidedly irritating nature, free lacrimation, with burning and itching in the nasal cavities, eyes and nasopharynx Frequently associated with this is a slightly asthmatic tendency It can not be cold, it is something in the nasal secretion and when the secretion comes to the surface and in contact with the air there is liberated some material (chemic) which acts as an irritant to the vasomotor system (peripheral terminal nerve filaments) and causes sudden congestion Such attacks are quite like inhaling ammonia fumes, and in such cases there is present an excess of ammonium salts in the saliva Owing to some chemic change in the secretions of the individual there is accumulated material within the system which in the point of accumulation reaches that period in which it overflows, and the secreting glands liberate on the surface this material, which when exposed to the air undergoes a chemic change In many instances, on examination of the saliva and the nasal secretions there has been found an excess of the sulphocyanids and the ammonium salts When this secretion is exposed to the air, free ammonia is liberated which I believe to be in many cases the cause of the attack The symptoms produced are identical with those of the inhalation of ammonia fumes When the secretion is exceedingly alkaline the patient will often have symptoms identical with those of articular rheumatism

CASES IN WHICH THE SECRETIONS ARE HYPERACID

The following case is an illustration

Mr C, aged 42, consulted me in regard to what he supposed to be a catarrhal condition, associated with ozena His breath was most offensive, but, although pronouncedly so it was not the penetrating, clinging odor observed in atrophic rhinitis with ozena He had observed the condition rather suddenly and it had existed continuously for some four or five years His history was absolutely negative as to any catarrhal condition other than an occasional cold He had consulted specialists both in this country and abroad, not only as to the possibility of the odor coming from the nose or some of the accessory cavities, but had also consulted specialists on dieases of the stomach, as well as having had a thorough inspection of all his teeth. He had been told that he had practically no catarrh, and, as his digestion was good and nothing found wrong by analysis of the contents of the stomach, it was quite puzzling as to the source of this odor. After a thorough examination, and knowing that the men under whose care he had been were most thorough and competent in their line, I reasoned that there must be some source of the disagreeable odor outside of the parts already mentioned. As this was in the winter of 1895, and as my attention had been called to the importance of the secretions by other conditions, as well as a statement made to me by the patient, I decided to investigate the saliva. The statement which he made to me, which was most significant, was this: "That, while his appetite was very good, and when his olfactory nerve was stimulated by the odor of a delicious meal, causing his mouth to water, the disagreeable odor and taste became so pronounced as to almost nauseate him." I then collected some of the saliva. The method used for its collection I learned from my experience in a dentist's chair, that while sitting with your mouth wide open for a few minutes you have a most profuse flow of saliva. This method practiced just before meal time, enabled the collection of quite a large amount of the secretion. The offensiveness of the secretion was at once detected.

CHEMISTRY OF THE SULPHOCYANIDS

In order to explain the chemic source of the offensive odor it is necessary to take up the chemistry of the sulphocyanids. As to the sulphocyanids which are present in the saliva, it is a chemic fact that most of the cyanids are actively poisonous and that a cyanid is formed, or is a compound, of cyanogen with a metal or radical. A sulphocyanid is a salt in which sulphur takes the place of oxygen in the acid radical. Cyanogen is a radical molecule having the structure CN, an acid compound of carbon and nitrogen. A radical is a group of atoms having unsatisfied valency, an unsatisfied molecule which goes into or out of combination without change to itself and which determines the character of compounds. A sulphocyanid is a combination, then, denoting the chemic combination of sulphur with a radical. When a sulphocyanid is eliminated the secretion in which the ammonium salts are in excess is alkaline, but when it comes in contact with the air, owing to the chemic change which takes place, it becomes an acid radical. Hence in many instances in which from our test we believe the secretion to be acid, it is really hypoacid (alkaline). This is most important, and in many instances in which from the test reaction we are led to conclude the reaction to be acid, it is in reality in the system an alkaline reaction and only becomes acid when, owing to chemic action due to exposure to air, certain materials are eliminated and the reaction changed. In some of the sulphocyanid combinations in which we get the bad odor as illustrated in the above case the chemic change causing such odor is as follows: Sulphur itself is an acid element which unites with oxygen to form an acid radical, but in a sulphosalt the sulphur takes the place of the oxygen in the acid radical. The sulphocyanid itself would be a sulphosalt in which, in combination, the sulphur would take the place of the oxygen and give off sulphuretted hydrogen. In a sulphosalt the sulphur takes the place of the oxygen in combination to form an acid. A sulphocyanid is a sulphosalt and when the sulphocyanid is in excess, when liberated and coming in contact with the secretion which contains moisture (H_2O) the sulphur would unite with the hydrogen, giving off free oxygen and form hydrogen sulphid. A radical is a group of atoms having an unsatisfied valency, and is really unsatisfied molecules which go into or out of combination. It is possible then to have in a hyperacid condition many chemic combinations take place. This chemic result surely verified the olfactory diagnosis in this case.

CASES NEITHER HYPOACID NOR HYPERACID

That cell nutrition depends on the chemistry of its supply is illustrated in disease processes associated with any form of infection or rise of temperature. This opens up an enormous field for speculation and investigation. The amount of infection, the peculiar chemic change produced by temperature, the materials absorbed into the body from infective processes, or the autoinfection from the intestinal tract, would in each condition produce its own peculiar chemic compound. Yet I believe a general basis can be reached, at least sufficiently accurate, from which to draw chemic and clinical deductions.

For example of peculiar effect on various structures in the body brought about by an altered chemistry in which the secretions may be neutral or irregular, I will quote from an article which was published in *American Medicine*, Feb. 8, 1903, in which I reported a number of cases of enlargement of the thyroid gland in which the cellular elements of the thyroid structure were increased, the enlargement not being due to distended vessels, cystic condition of the gland, or new growth.

I reasoned the matter out as follows: It is a well-known physiologic and therapeutic fact that certain drugs have a selective action on certain tissues or organs of the body, e. g., belladonna, with its selective action on the pharyngeal surface, sodium phosphate, with its selective action on the liver, etc. It is also a physiologic fact that the normal chemistry of the body controls the normal secretions from the various secretory organs, that any perversion from the normal necessarily alters the character and chemistry of the secretion, and that the products of such alteration act as irritants to certain parts of the body, the difference between this and drugs administered is that one is introduced into the body and one is manufactured within the body. I, therefore, reasoned that under certain conditions there is precipitated—due to perverted chemic reaction—a certain material, which, circulating through the blood had a selective action on certain tissues, in the cases observed such selective action occurred in the thyroid gland, acting as an irritant to that gland. While the treatment of these cases reported was somewhat theoretical, I believe, however, that the drug introduced into the body, by its chemic action, altered the chemistry of the material which was acting as an irritant, either rendering that irritating material inert or forming a compound which was nonirritating.

In regard to the pathologic chemic process producing such reactions of the secretion, it is a well-known clinical and laboratory fact that a study of the products of the secreting organs, which in their excretory functions throw off waste material, gives us by deduction a fair idea of what process is going on within the body. Yet this excretory secretion or material is altered in its chemic composition and controlled by the chemic constituents within the body proper.

There is no question that under certain conditions—for example, when the secretions are acid or alkaline—the chemic process taking place within the various secretory glands must vary, and the product of such variation in these unknown quantities must be somewhat the same as the variations we would obtain in dealing in the laboratory with known compounds. In other words, that the body is largely a chemic laboratory, having on hand a certain amount of material and having added to it daily ingredients through the respiratory and alimentary tract Now, any perverted conditon from what is known as the normal chemistry may bring about a series of changes and produce chemic products which may be harmless or productive of disease processes On no other basis can we explain the various diatheses and the precipitation of certain materials in the tissues of the body

The altered chemistry of the saliva presents many possibilities from an etiologic standpoint Many forms of lesions of the mucous membrane of the nose, nasopharynx, larynx, mouth and gums, as well as diseases of the stomach and intestines, may be brought about by the altered chemistry of the saliva A great many morbid processes are traced to uric acid in some of its many forms, but I believe that many other substances, especially hyperacid conditions, equally important are deposited and eliminated, which substances act as irritants, producing apparent local lesions It is a well-known clinical fact that saliva from certain individuals is exceedingly poisonous, as is indicated by the infectious wounds produced by the bite of such individuals, showing that the saliva may be the site of poisonous pathologic, as well as physiologic, compounds This is especialy true in the sulphocyanid cases

Unquestionably the chemic reaction of the secretions of the body is an important factor in the susceptibility of individuals to disease I think there is no doubt that the fact that at one time the individual resists disease and at another time succumbs can be largely explained on this basis To be sure, it is a question of resistance on the part of the individual, but that resistance is largely controlled by the chemistry of the cell or secretion It also demonstrates the fact of the accumulative phenomena of certain of the diseases, as is illustrated in uric acid diathesis, which Haig has described as the uric acid storm There is no reason why these same phenomena could not occur as the result of the accumulation of other materials brought about by chemic changes which lessen oxidation and tend to precipitation and accumulation of various morbid products

The administration of drugs for the relief of, for example, an infective process, probably affects such a process beneficially, owing to the fact that in its action it changes the chemistry of the secretions and blood constituents, thereby producing a chemic compound which either prevents the formation of infectious material or alters the nidus of infection to such an extent that it is not suitable for the growth of bacteria

While my investigations are incomplete and fragmentary, I am convinced that from the study of the saliva we can determine to a great extent any variation in the chemistry of the body As these various secreting glands receive from the blood the supply from which they elaborate certain chemic compounds, if an analysis were made of the composition of such secretions it would give a good index to the general condition of the individual, and while in many cases the deductions would have to be based on or associated with clinical observation, I have found them to be of immense value from a standpoint of diagnosis

The fact that the reaction of the secretion may be apparently acid when there really is present an alkaline condition, explains to us many of the cases in which, from an acid basis, our treatment has failed That such [illegible]dition may exist has been shown by Douin [illegible] in their studies of the blood, that the [illegible]e plasma is really acid and if waste products are not eliminated this acidity is increased The secretions and excretions then also become of an acid reaction

The irritating gases which form in the stomach and intestines and produce laryngeal and pharyngeal irritation, are the result of chemic changes in the intestinal secretion, and such chemic change in the secretion can be demonstrated by a study of the saliva That autoinfections and chemic changes in intestinal secretions have a marked general effect on the individual is well known Such material absorbed into the system will unquestionably alter the chemistry of all secreting glands, and the compounds formed by such alteration which affect the individual can only be determined by the study of organic chemistry The asthmatic conditions which are not associated with any organic lesion, I believe can all be explained on this basis, and when treated accordingly can, in many instances, be relieved

In examining the secretion and excretion of the body, we can obtain as good an index of the systemic condition of the individual by a study of the saliva as by a study of the urine, in the urine we have only an index of the waste material, while in the saliva we have products of elimination which return into the body to perform a physiologic process

Another important factor to be worked out is the different chemic changes which take place in individuals suffering with so-called functional diseases and those suffering from organic or structural changes In the functional we have a perverted chemistry, which may be brought about by many causes, such as faulty elimination, from the kidneys or liver, and perversion of secretion from the intestinal tract, autoinfection from the intestinal tract, also chemic changes of the secretion illustrated in mental tension from fright, worry and anger, while in the organic lesions we have to deal with a structural change in tissues, with retrograde metabolic changes, in which there is also associated inflammatory processes with their accompanying phenomena and physiologic and pathologic effect on the individual

EFFECT OF CLIMATE AND ALTITUDE

The effect of climate and altitude on hay-fever individuals is interesting from a number of standpoints If the disease is distinctly a neurosis, why should the patient, as a rule, improve in a high, dry altitude, when such altitudes are decidedly irritating to a nervous individual? Why is it that an individual, after having hay fever for several years, will miss one season, or even two, having no treatment whatever? Personally, I think the answer lies in the individual, at least in a majority of cases and that the secretions of such individuals having changed under certain conditions were non-irritating The famous case of Mackenzie's, in which the artificial rose produced an attack of hay fever, surely is strong evidence in the line of neurotic origin At the same time, in a nervous individual with a perverted nutrition and necessarily perverted secretion, any particle of dust or anything whatever that would stimulate the nasal mucous membrane would promote the flow of secretion, which secretion being decidedly irritating would at once bring on an attack

INDIVIDUAL VARIATIONS IN SUSCEPTIBILITY

Another interesting fact is this That in the cases which I have watched closely for the past eight years, the hay fever was no respector of persons as to weight that some individuals who were stout had the worst form of hay fever while others who were very thin had equally bad attacks

I also noticed that in a number of such individuals, when the secretions were changed and irritation ceased in some of the stout cases, they lost flesh rapidly, one patient losing as much as 40 pounds, while the thinner individuals improved in weight This led to a comparison of the chemic examination of the various individuals The very thin individuals in 90 per cent of cases had an excess of sulphocyanids which, of course, was acting as an autotoxic infection, while in the excessively stout individuals the reaction of the secretion varied, usually neutral or acid, which, of course, predisposes or causes lessened oxidation and increase of fatty tissues Also that in individuals with an excess of the sulphocyanids, the individual always has the appearance of an autotoxic infection, deranged digestion and intestinal tract, and with the relief of this condition always shows rapid improvement

Is it not possible that certain pollens coming in contact with the nasal mucosa, thereby acting as stimulants, promote the flow of secretion, and when such secretion is poured out on the surface either, as I have stated before, as an irritating secretion or when combined with the pollen, a chemic change takes place and an irritating material is produced? Dunbar's inoculation theory surely proves this statement, and agrees exactly with what I have said as to the secretions Under this class of cases would come the rose cold, the ragweed, the horse fever, hay fever, rye fever, etc Think of the difficulty of procuring an antitoxin for horse fever! In all such cases I think that the secretion is the predisposing and the extraneous material or pollen is an associated factor

As is shown by Dunbar, the inoculation method is not successful in all cases, which is easily understood, as the chemistry of the secretions in the various individuals are markedly different, so that instead of an antitoxin for exciting factor, use preventive measures by altering the secretion My own experience surely justifies this statement Unquestionably, certain individuals, owing to the low grade of their vitality and neurotic temperament, are more likely to be subjects of this disease than persons of healthy type, nevertheless, many individuals of most perfect physical condition are the worst sufferers from this peculiar and annoying disease and while I do not wish to be understood or quoted as saying that all cases of hay fever can be cured on this basis, my own experience does show that between 80 per cent and 90 per cent of the cases can be relieved and cured When I say cured, I mean in the same sense as you would speak of curing a cold, and most certainly if the condition of the secretion changes and the irritating material returns, if the individual is exposed to the same irritants, he most certainly would have another attack

1517 Walnut Street

DISCUSSION

Dr E C Kirk, Philadelphia—My interest in this matter originated with a paper read by Dr Michaels in Paris in 1900, subsequently I spent some time with him in his laboratory and went over the subject in detail I have been studying the changes in the saliva since that period, and have become convinced of the importance of the generalizations made by Michaels that the chemical composition varies quite constantly with certain pathologic states, especially in relation to faulty metabolism My own studies have been largely confined to the pathologic conditions of the soft tissues of the oral cavity, especially of the retentive tissues of the teeth The method of study suggested by Michaels, the use of the micropolariscope, first made it possible to accurately know the chemistry of the saliva, it gives a means of analysis which is extremely delicate and is as accurate in qualitative test as the gravimetric method could be With the use of the polariscope we can detect the salts by polarized light It is quite true that a study of this subject tends to confirm the general views entertained regarding the etiology of gout and other similar conditions We have in the arthritic subject a condition of insufficient oxidation with large quantities of carbon dioxid dammed up in the blood plasma It is part of the function of the kidney epithelium to return sodium bicarbonate to the blood and eliminate the acid phosphates through the urine as a result of the mass action of carbonic acid on the basic phosphates of the blood plasma When the condition becomes excessive and chronic, it causes the loss of enormous quantities of phosphorus resulting in phosphorus starvation, and during that period other waste products, irritative in character, manifest their presence Prominent among these is oxalic acid Oxaluria generally means a state expressed in the terms of calcium oxalate Enormous quantities of sodium oxalate, however, make their presence felt about the time phosphatic starvation supervenes The patients then become neurasthenic, and in that connection also we have certain local phenomena I have watched the development of leucoplasia in the mouth and its subsequent degeneration into epithelioma I am of the belief that there is a definite relation between the irritation which these waste products produce and the conditions of the nasopharynx described by Dr Kyle I regard them as productive of direct irritation to the mucous surfaces, and that they may even stimulate the tissues to the formation of new growths

Dr Judson Daland, Philadelphia—A proper appreciation of the chemical causes of this affection indicates a plan of treatment which has given brilliant results It is not at all improbable that certain spasmodic bronchial affections that are usually considered under the name of asthma may have a like cause and a study of the disease from this standpoint may yield similar therapeutic results The profession has been gradually recognizing the importance of hyperacid conditions of the upper respiratory tract and mouth, but Dr Kyle is to be complimented on drawing attention to direct poisonous inflammation of sulpho cyanids and of the marked local irritating effects of hyperacid conditions which are frequently in association with ammonia compounds, and, at times, free ammonia These observations are of importance to the general practitioner because of their prejudicial influence on the general health, and there can be little doubt that certain cases of general toxemia are due to this cause On the other hand, I am inclined to believe there are certain cases of toxemia of intestinal origin, usually fecal, that play an etiologic rôle in the production of the morbid chemical state of the nasal secretions and saliva. If we remember that within a very few minutes after the taking of lithium, it can be discovered spectroscopically in the saliva, and that normally within eight minutes after the swallowing of a solution of iodid, iodin can be detected in this same secretion, we realize how rapidly is the diffusion of these soluble substances and how promptly the salivary glands excrete these substances which here have the peculiarity of again being swallowed to again be absorbed into the circulation I shall in the future give especial attention to the chemistry of the saliva and nasal secretions, more especially in well marked examples of auto intoxication, nervous asthma, hay fever and neurasthenia

Dr E Fletcher Ingals, Chicago—The paper recalls to my mind the remark of the professor of medicine when I was a student, who, when asked what he would do for a certain disease, replied that it would depend entirely on what was the matter It is encouraging to find some men searching among the living for the causation of disease. Pathologists deal with the dead, and hence become therapeutic agnostics In the past nearly all medicinal treatment has been empirical, but the kind of experimentation outlined in this paper is destined to do much to enable us to know for what reason we are giving our remedies It is certainly unwise to continue to give medicines, the action of which we can not satisfactorily explain The pathologic side of disease is of great importance, but we should bear in mind the fact that over 90 per cent of the physician's work is therapeutic in character, and that nine out of every ten sick people get well Our aim should be to try to cure them more quickly, and it seems to me that the greatest work before the profession in the coming years is along the line of therapeutic research In our hospitals we find bright, energetic internes, but quickly discover that they have little knowledge of therapeutics In the large hospitals with which I am familiar nothing whatever has been gained in the way of therapeutics for the past twenty five years It is difficult for the older members of the profession to do research work, and the younger men have not been encouraged to undertake it in this line

Dr W H F Fitzgerald, Hartford, Conn —I believe the position taken is correct that these conditions are due to irritative changes, basing my opinion on the history of twenty four cases I have worked at myself during the past two years There can be no question about the irritative effect on the lining membrane of the nose, and it really makes little difference where this area is located In my opinion, it is due entirely to the fact that the individual in question does not use his nose' As a class, we do not know how to breathe, and just so long as we go on breathing through the mouth we are bound to have these irritated areas

A man may go to a certain district and the irritating pollen or organism attacks a particular irritated area of the mucous membrane of the nose and produces the condition of hay fever Of these twenty four cases treated, I have had but one case return, I have heard from all of them, and they have stated that they have had no recurrence This is due largely to the fact that they are now breathing as they never did before I see that they breathe properly at night, for I plaster their mouths up during the night and make them exercise the nose during the day In the treatment of these cases I have employed no therapeutic measures at all after obliterating the irritable areas One of the worse cases I ever saw was that of a minister who was prostrated two or three days out of every week, and at one time for nine months continuously He then lived in the west, and for the past three years has been living in the east, and his trouble was as great in one locality as in the other I found he was a very bad breather, and I have succeeded in making a good breather out of him He recovered entirely, and even went back to his former residence looking for trouble; but failed to find it

Another case was that of a woman who used from forty to sixty handkerchiefs a day during a period of thirteen years The condition was complicated during the thirteenth year with attacks of asthma which kept her awake most of the night I removed obstructions, irritable areas, etc , and discharged her over a year ago She has since been averaging not more than one handkerchief a day, and says that she has had but one slight attack of asthma in the course of the year She states that she often had the feeling that if she took one breath through her mouth she would have another attack, and that under these circumstances she often resorted to the plaster during the day Since she has become a normal breather this has not been necessary

Dr W S Anderson, Detroit—Has Dr Kyle made any study of the secretions of the pharynx in mycosis leptothrica? It runs a very stubborn course and occurs usually in healthy persons

Dr J Holinger, Chicago—There is a series of experiments which have a bearing on this subject of the chemical composition of the saliva and all the juices of the digestive tract with reference to the food taken In experiments with dogs, it has been found that if a certain character of food is offered to the dog the saliva has characteristic changes going very far in the direction spoken of How can this series of experiments be brought into connection with the paper?

Dr G V Woollen, Indianapolis—I have examined the statistics relating to the surgical treatment of these cases and have not been satisfied that they offered a definite solution of the problem When Sajous' book came out, dealing with peculiar idiosyncrasies, external irritation and diseased noses, we thought we had the solution in a definite form, but the idiosyncrasy suggested did not wholly satisfy me because this condition of the system is present at all times of the year I then began, not chemically but clinically, to gather and observe these secretions I have carried this investigation to an extreme degree ever since and am convinced that the secretions do not offer a solution of the whole matter I also felt that if I could control the acid condition of the system I should have the key to the whole matter, but that was a disappointment I am disappointed to day There has been a great deal said with reference to the mouth and pharynx, but these do not explain the conditions in the nose As Dr Ingals has intimated, the discussion is in the right direction and younger men will perhaps work out the problem along the chemical line

Dr D B Kyle—Many of the points which have arisen in the discussion will be found answered in the remainder of the paper, all of which was not read on account of its length I omitted to say that the chemical reaction of the saliva is so nearly the same as that of the nasal secretion that I did not use the terms nasal and salivary each time In some cases, if tested at the same time, one will give an acid reaction and the other alkaline, but if the chemical composition is studied they will be found not to differ, the chemical reaction having changed after exposure to moisture and air

As to mycosis, if it is a genuine case of mycosis and not keratosis, it is a well known fact that bacteria grow better in alkaline media than in acid I have made a careful examination in a few cases of pharyngeal mycosis and the secretion was alkaline in reaction

---

POISONING BY WOOD ALCOHOL

CASES OF DEATH AND BLINDNESS FROM COLUMBIAN SPIRITS AND OTHER METHYLATED PREPARATIONS [*]

CASEY A WOOD, M D
CHICAGO
AND
FRANK BULLER, M D
MONTREAL

With the kind assistance of the profession in the United States and Canada, we have been able to report the following instances of methyl alcohol intoxication, most of them hitherto unpublished

The list of deaths and cases of blindness following the ingestion of "Columbian spirits" and other forms of wood alcohol, as well as methylated "Jamaica ginger," lemon "extract," "bay rum," "cologne water," "witch hazel," essence of peppermint, essence of lemon, etc , not to mention all sorts and kinds of other official, domestic and proprietary remedies into which alcohol enters, has lately grown to alarming proportions This record of death and blindness has been made in recent years only, since the cheap, "deodorized" methyl alcohol [untaxed, retail price 50 cents a gallon, ethyl alcohol, taxed, retail price $2 60 a gallon] has been put on the market

Wood alcohol and methylated spirits made by the old processes subserved useful as well as harmless purposes They possessed practically all the solvent and other properties required for the various arts in which they were employed, and no one thought of drinking them or employing them as adulterants in foods or drugs Indeed so abhorrent to the organs of taste and smell was even a small percentage of wood spirit in any mixture, that no person in his senses would drink so nauseous a compound, however diluted and disguised, or however much he craved an alcoholic drink

---

[*] Read at the Fifty fifth Annual Session of the American Medical Association, in the Section on Ophthalmology and approved for publication by the Executive Committee Drs Frank Allport, John F Weeks and R I Randolph

With the advent of preparations like "Columbian spirits,' 'colonial spirits," "eagle spirits," *et hoc genus omne*, the principal safeguard against poisoning by methylic alcohol has been removed Some of these deodorized alcohols are with much difficulty distinguished by the laity from pure ethyl alcohol Hence it is that in spite of ordinary precautions, such as labeling bottles of these preparations 'not to be taken internally," they have been and are now, through accident and design, much used as substitutes for grain alcohol

The appended histories by no means constitute a complete list of deaths and blindness from wood alcohol poisoning A more careful canvass will, we are sure, bring to light numerous additional instances of this intoxication that we have not been able to gather during the limited time at our disposal The remarks of Dr Moulton properly apply to many localities where grain alcohol beverages are difficult to procure

> Cases (of wood alcohol poisoning) are of frequent occurrence in Indian Territory, where the sale of ethyl alcohol is strictly prohibited by the United States government, so that those who crave stimulants drink anything they can get I can safely say that in that country at least fifty deaths have occurred from this cause in the last few years

The same remarks apply, though in a less degree, to methyl alcohol blindness A circular letter on this subject was addressed by Dr Wood to a large majority of the ophthalmic surgeons in the United States and Canada, and there is good reason to believe that, as a result of these inquiries, descriptions more or less complete of most of the well-defined and recent cases of wood alcohol amblyopia and amaurosis will be found in this report At the same time, since blindness from methylated liquids was practically unknown until the recent introduction of this "purified" product, medical men may well be excused for not recognizing, for attributing to other causes or for afterward forgetting cases that several years ago came under their notice

For purposes of subsequent reference we have divided these histories into four classes

Class A —Published cases of blindness or blindness followed by death, due to the drinking or inhalation of methyl alcohol The cases comprised in Class A were collected, abstracted and tabulated by Dr Buller

Class B —Cases (hitherto unpublished) of blindness or blindness followed by death from drinking methylated liquids

Class C —Cases (hitherto unpublished) of blindness from methyl alcohol absorbed through the lungs or skin, or both

Class D —Cases (hitherto unpublished) of death from methyl alcohol poisoning, without history of previous blindness

The cases detailed under Classes B C and D have been collected and edited by Dr Wood The sources of the information in the last three classes, arranged in alphabetical order, will be found at the head of each history

SUMMARY OF PUBLISHED CASES

The tabulated records (to appear later in this article) of 54 of the published cases show the ages of individuals to be from 21 to 65 years, mostly about middle life Of 51 we note Sex, males 47, females, 4 Habits of life, 8 were or had been hard drinkers, 9 admitted occasional indulgence, 3 habitually temperate 30 habits not stated but no doubt most of them were more or less addicted to alcoholism Six are reported to have used tobacco in excess, as well as alcohol Occupations Artistic painter, 1, attendant, 1, bricklayer, 1, barber, 1, carpenter, 2, china decorator, 1, convicts, 3, dressmaker, 1, farmer, 2, housewife, 2, hotel keeper, 1, miner, 1, millhand, 1, workmen, 1, mechanic, 1, soldier, 1, sailor, 3, woodsman, 1, watchmaker, 1, upholsterer, 1, not stated, 20

As to the mode of occurrence In most instances the trouble occurred as a result of a spree, generally together with friends or associates, *in a few instances* the alcohol was taken by accident The preparations nearly all undoubtedly contained the drug, methyl alcohol, as the sole or chief toxic ingredient In 28 cases methyl alcohol was specified, in 12 Jamaica ginger, in 1 Columbian spirits, in 2 essence of lemon or cinnamon, in 1 cologne spirits, so called, in 1 an unknown alcoholic mixture, in 3 methyl alcohol vapor was inhaled

As to the quantities consumed The methyl alcohol series varied from half an ounce to 16 ounces The Jamaica ginger from 3 ounces to 25 ounces, the larger quantities usually in divided doses over a period of several days Columbian spirits from 6 ounces to 8 ounces and in 2 cases quantity unknown Essence of lemon, 5 or 6 ounces in one case in the other quantity unknown Cologne spirits less than 8 ounces Of the unknown strong alcoholic liquor, 15 ounces Of the three inhalation cases quantity inhaled conjectural

As to general effect Headache was mentioned in 19 cases as a conspicuous symptom, gastric pain in 11 nausea and vomiting in 26, dilated pupils in 20

The results as to visual disturbance were 16 total blindness, 3 total blindness of one eye, 15 partial recoveries, 7 recoveries, 10 remaining cases terminated fatally, sight became dim in three hours in one case, six hours in 1 case, eight hours in 1 case, ten hours in 1 case, twelve hours in 2 cases, twenty hours in 1 case, twenty-four hours in 19 cases, forty-eight hours in 5 cases, three days in 2 cases, six days in one case, seven days in one case, sight became lost in twenty-four hours in 10 cases, in thirty hours in 2 cases, in twelve hours in 2 cases, in forty-eight hours in 3 cases, in three days in 3 cases, in four days in 3 cases in five days in 2 cases, in six days in 2 cases in seven days in 1 case, in eight days in 1 case, in seventeen days in 1 case Of the remaining 21, facts in this connection are not definite

Certainly few members of the medical profession, and practically no one of the general public are as yet aware that methyl alcohol taken into the system in moderate or considerable quantity not infrequently causes death, after the manner of the cases just cited More than this, the people are still less cognizant of the fact that a certain proportion of those who survive the poisonous effect of the drug are condemned ever afterward to the miseries of greatly impaired vision, and, indeed, not infrequently to absolute blindness It is a remarkable circumstance that notwithstanding the accumulated evidence of many similar recorded facts, there still exists a widespread unbelief in the toxic action of wood alcohol Not long ago, with the object of discovering cases of methyl alcohol poisoning known to have occurred in Canada, Dr Buller wrote to thirty or more Canadian oculists, asking each one for his experience in this direction One sent this reply, which is worthy of record It runs as follows

> I have not met with any case of blindness from drinking wood alcohol nor heard of any, *notwithstanding the fact that*

I live quite near one of the largest distilleries of methyl alcohol in Canada The prevalence of the habit of intoxication from wood alcohol must be greatly exaggerated

The italics are Dr Buller s Two only sent records of cases they had seen, some fifteen replied that they had no experience

Altogether, Dr Buller knows of only five reported and three unreported cases in Canada, and has heard of four others, without so far having been able to obtain facts regarding them Of the five reported cases three if not four actually occurred in the United States giving, therefore, up to the present time only one reported and three unreported cases which have happened in Canada It would thus appear that wood alcohol poisoning occurs much more frequently in the United States than in Canada, since of the 54 cases of which Dr Buller has collected details some 47 occurred in the United States and two in Europe

B —CASES (HITHERTO UNPUBLISHED) OF BLINDNESS OR OF BLINDNESS FOLLOWED BY DEATH FROM DRINKING METHYL ALCOHOL

CASE 1 —(From Dr James A Bach and Dr Joseph Schneider Milwaukee Wis)

D McK Ashland, Wis, on Nov 26, 1903, was taken ill with abdominal pains and diarrhea, while engaged in "scaling" lumber in the northern woods of Redcliff, Wis Being far from any doctor, he secured a bottle of Hinkley s bone liniment and took the same internally according to directions a teaspoonful every hour for a few hours, then less often This treatment he continued from November 26 to November 27 inclusive On November 29 Mr McK found his sight leaving him Within twenty four hours he became totally blind in his left eye and partially so in the right eye He thereon consulted a doctor in Ashland, Wis, who told him that the "liniment" had probably "done the work" The patient is now (May, 1904), a man of about 46 years old, strong and robust in appearance and apparently has no bad habits There is nothing in his history to account for his condition but the fact that he took the quack medicine as above stated, which was followed so promptly by practical blindness The left disc is gray white and the smaller papillary capillaries and vessels are absent with the exception of the lower macular artery, which is still seen The larger arteries and veins are reduced in size about 20 per cent V = no perception of light The right disc is also whitish, with a decided diminution of capillary circulation, but not so marked as the left V = 3/40 The visual field in the right eye shows a large, absolute scotoma not quite central, with concentric limitation marked[1]

CASE 2 —(From Dr Wilfrid Beaupré Quebec Canada Reported by Dr Frank Buller, Montreal)

J D aged 42, machinist, was in the habit of indulging in liquor to excess every month or two After one of these "sprees" on March 6, 1898, having no more whisky on hand, he drank about half a tumblerful of methyl alcohol from a bottle in the house He took this one drink only and in a few hours drove to the doctor's office nearly blind His vision in either eye was finger counting at nine inches He had intense photophobia and pain in the head, the papillæ were white, but the retinæ showed no particular change He was immediately put on potassium iodid with bromids For a time there was considerable improvement in his vision so that he returned to work On March 20, however, he again noticed failing sight and when Dr Beaupré saw him on March 21, V R =15/40, V L =15/200 The iodid was continued and he returned on the 31st when V R =15/20, V L =15/40 April 18 1898 V R =15/40, V L =15/100 April 25, V R =15/50 V L =15/100 Then citrate of iron and strychnia were prescribed On May 9 the nerve heads were decidedly white V R =15/75, and V L =15/200 The patient's eyesight now became so defective that he was obliged to abandon his work and engage in selling candy in a small store. Even then he found it difficult to recognize coins or to distinguish the figures on bank bills When Dr Beaupré last heard of him he had entirely lost useful vision

CASE 3 —(From Dr M H Bell, Vicksburg, Miss)

M B, man, white, aged 50, occupation, blacksmith Now in the Mississippi State Charity Hospital under Dr Bell's care. V, each eye, = light perception, eyes look entirely normal externally Ophthalmoscope shows no marked changes There is more pigment scattered over the fundi than is usually found Nerve heads normal, vessels, both veins and arteries, are small, two-thirds usual size Two years ago he was working in a "dry" county and, as was the habit there, used "peruna," Jamaica ginger, etc, as stimulants The patient's usual drink was the ginger, and he told Dr Bell that he had been taking an occasional drink of it for three or four months While at work one day he suddenly became blind, so that he had to be led home by another man This was followed by nausea lasting two or three hours On the same morning he had taken two or three drinks of ginger, rather indefinite as to quantity On the following day his sight returned, but since that time gradually failed for eighteen months, after which it has remained the same He can not now go about without some one to guide him Although no analysis was made of these beverages the clinical history and the other facts in the case point directly to methyl alcohol intoxication

CASE 4 —(From Dr George H Bicknell, Omaha, Neb, Dr George B Simpson, Sheridan, Wyo Dr Casey Wood Chicago)

G W A, ranchman, Scotch, aged 35, had always had good health An examination by Dr W A Evans of Chicago proved him to be free of syphilis rheumatism, or any disease of his internal organs Blood, urine, etc, normal On July 4 1899 in company with a number of companions, he proceeded to celebrate the day by getting gloriously drunk It is not known exactly what sort of alcohol the party imbibed, but it was considerable in amount For the following four days he suffered from severe and constant frontal headaches, nausea, pain in the abdomen, frequent fits of vomiting and difficulty in breathing About forty hours after the spree began he noticed a "dazzling" sensation in front of his eyes and in two or three hours more was totally blind Dr Wood saw him in consultation with Dr Bicknell on July 28 1889, when he said that on July 25 he first noticed his returning eyesight This improvement in vision continued for a while, but there was a relapse about the time he left for his home in Scotland, the following November On July 28, 1899, V R =no p l, V L =hand movements in the lower third of the field Pupils widely dilated Tension normal Light reflexes absent doubtful as to accommodation Lenses showed a few striæ Both fundi exhibited blurred papillary outlines with loss of the usual transparent appearance of the nerve heads Retinal veins somewhat engorged, arteries smaller than normal This patient was vigorously treated by Dr Simpson with potassic iodid, electricity and, later, was ordered full doses of iron and strychnia Improvement for a time set in with enlargement of the small eccentric field for white in the left eye In July, 1899, he was able to see shadows and the outlines of large objects in the upper part of the right field and to count fingers at six inches with a small area in part of his upper left retina On Nov 13, 1899, his vision was much worse He, at that time, perceived hand movements in the left eye eccentrically, but there was no light perception in his right eye The fundus pictures were then greatly changed The nerve heads showed shallow atrophic excavations, the discs being whitish, veins of normal size, arteries small Tension normal in both eyes The patient was given a letter to Dr Argyll Robertson, Edinburgh and has not been heard from since

CASE 5 —(From Dr Emil Bories, Seattle, Wash Reported by Dr Hamilton Stillson, Seattle, Wash)

A German, aged 27, cabinetmaker by trade, drank about two ounces of wood alcohol that was used in a saloon for filling cigar lighters Seen about an hour afterward Was in deep stupor, snoring, stertorous breathing, could not be aroused by his companions Features pale body cold bloody froth from mouth, pupils dilated, no reflexes Had him taken to city jail, where, after heroic rubbing, applying of hot packs, and hypodermic *injections* of strychnia, he was sufficiently aroused to answer his name Recovery Vision, as well as his gait, was affected for several days

---

[1] An examination of the proprietary remedy referred to in this report was recently made for me by a competent chemist and found to contain a large percentage of methyl alcohol —C A W

Case 6 —(From Dr A H Brundage and Dr James W Ingalls, Brooklyn, N Y)

Mrs M, living at East Brooklyn N Y, aged about 35, was addicted to the excessive use of alcoholic drinks and occasionally drank grain alcohol with water and sugar Having heard that wood alcohol was about the same thing but much cheaper she purchased half a pint and drank most of it

She was found partly unconscious and sweating profusely She was nauseated, vomited severely and was delirious, with pupils dilated Seemed chilly Vision gradually became blurred Died in about thirty six hours from the time the wood alcohol is supposed to have been drunk

Treatment—Free syphonage of the stomach, cold effusions to head, caffein, digitalis, pilocarpin, external heat, oxygen, rectal injections of hot coffee, and also of normal salt solution

Case 7 —(From Dr Henry D Bruns, New Orleans La)

A man, about 50 years of age came to the clinic in 1902 with the following history He had made toddy one evening with Columbian spirits, of which he took several drinks, *using at* least an ounce of the wood alcohol Shortly afterward his vision completely failed him He then regained much of his sight for a brief period but finally became totally and permanently blind[2]

Case 8 —(From Dr Henry D Bruns, New Orleans, La)

This case,[2] is that of a man of middle age who ingeniously concocted a "highball" whose spirituous portion consisted of a popular 'antiseptic" He promptly became blind but when seen a week later had somewhat improved in vision He left the clinic and it is not possible to say whether the improvement held or not Dr Bruns had the proprietary article employed by this patient analyzed by the chemist of the board of health It contained a large percentage of wood alcohol

Case 9 —(From Dr A. E Bulson, Jackson Mich , Dr Pray, physician to the State Prison, Michigan, Dr J F Byington, Battle Creek, Mich)

John C convict, aged 48, appeared March 5, 1903 at morning sick call and asked to be excused from work He walked unsteadily and the pupils were somewhat dilated He said he had eaten no breakfast and had vomited On accusing him of having taken some drug he admitted that he had drunk wood alcohol This was used in the prison shirt shops for dampening collars for the purpose of turning them The mixture was equal parts of wood alcohol and water with glycerin, 2 ounces to the pint. On March 3 patient consumed 10 ounces of this mixture, and on the next day 4 ounces He was sent to the hospital and treatment, consisting of large doses of bismuth given to quiet the intense, burning pain in the stomach At 7 p m although the electric light at the head of his bed was turned on, he asked to have a light in other words, he was apparently blind Dr Pray says the blindness came on quite suddenly He instituted alternate hypodermics of pilocarpin and strychnia every four hours (1/16 gr pilocarpin, 1/30 strychnia) and potassic iodid grs 20 On March 10 the patient could distinguish the hand held close to his eyes March 15 he could see quite plainly March 18 again failing vision, and on March 24 very poor vision Discharged from hospital March 27 Strychnia and potassic iodid continued in pharmacy Vision 7/30 Dr Bulson examined this case later and found only light perception in the right eye with blue white discs and marked retinal changes, the former more pronounced on the temporal side In the left eye V = 3/20 for central vision about the same changes in the papilla There was a decided contraction of the peripheral field In September, 1903, Dr Byington again examined this man who, then a blind peddler, presented himself with the request that the physician, as a matter of charity give him a "statement of his case" so that he could the better dispose of his small stock in trade Dr Byington *made only* the superficial examination demanded by the patient and found V = finger counting at 3 to 4 inches in each eye, associated with white atrophy of both nerve heads—each lamina cribrosa being distinctly visible at the bottom of a shallow, atrophic excavation

Case 10 —(From Dr *Homer* Collins, Duluth, Minn)

J A, aged 40, carpenter, Cromwell, Minn , was in the habit of going on *several sprees yearly*, but avoided liquor between these sprees Used tobacco, smoking or chewing about 'ten cents' worth a week" On Nov 22, 1901, with a companion, he drank about one dozen bottles of *Jamaica* ginger bought at Cromwell The following day the companion vomited freely, but his eyes did not suffer The patient vomited "everything' the next day and his eyesight began to fail at once On the second day he could distinguish only light from darkness, and remained in this condition for two days Then improvement of vision began and continued until about Dec 12, 1901, when V = 2/200 (white letters) in either eye Right half of each field was covered by a scotoma, the most acute vision being eccentric, to the nasal side of the fixation point In the left eye the field is very little contracted, central vision is best. There is some tenderness above and behind the eyeballs The patient gave the history just outlined and stated that immediately after the poisoning he had considerable pain in his eyes, which were too sore to touch He was put on pilocarpin treatment, under care of the county physician, and on December 22 thought he could see a little better but tests showed no improvement, and there has since been little change in his condition Bilateral post neuritic optic atrophy

Case 11 —(From Dr Coote of Quebec, and Dr Frank Buller, Montreal, Canada)

A man between 28 and 30 years of age, well built and healthy in appearance, without any history of a serious illness, while working in a lumbering camp, caught a slight cold To cut the trouble short he took what he considered a big dose, about a wineglassful of methylated Jamaica ginger He commenced to suffer from violent headaches and retching shortly afterwards Some twelve or fourteen hours later his sight commenced to grow dim A second dose was then taken and his sight grew worse He was taken home and, with the exception of his eyes, he was shortly well again About three months later, when he appeared at the hospital, central vision in both eyes was completely lost Toward the periphery of the field of vision in both eyes a few patches of retina remained sensitive to light and fingers could be seen at a couple of feet The pupils reacted to light and on convergence Both discs were pale (not white) and the margins well defined, the arteries and veins were contracted, but not equally, the media were clear He was kept in the hospital for some weeks, but the treatment was of no avail

Cases 12 and 13 —(From Dr Homer Collins, Duluth, Minn)

In the year 1900 (exact date unobtainable), an Indian from one of the Minnesota reservations accompanied by an Indian attorney (G H B), consulted Dr Collins The history of the case showed that at least six Indians, having procured a supply of essence of lemon, drank freely of it Three died promptly, evidently from the direct effects of the beverage, one of them becoming blind before death Two others suffered considerably, but recovered without apparent damage to any of their organs The sixth Indian, the patient under discussion, survived, but became totally blind An ophthalmoscopic examination revealed marked atrophy of both optic nerves[3]

---

[2] This case, as well as the next one, is entered in the tables published by Dr Bruns in the annual report for 1902 of the New Orleans Eye Ear Nose and Throat Hospital

[3] Through the kindness of Dr J W Chamberlin of St. Paul, Mr G H B wrote me the following note, giving further information regarding this matter 'Your letter of inquiry reached me at White Earth Minn In reply an Indian trader named Malone (afterward prosecuted by the U S) sold to several Mille Lac Chippewa Indians a number of bottles of essence of lemon on June 28 1897 which they drank in lieu *of alcohol* when that had been exhausted A large number of Indians drank alcohol only six or eight drank the essence of lemon The latter were all taken seriously ill within an hour after they began to drink the essence and three of them died before morning I can recall the *name of only one of* those who died a chief Mah-che-kewis. Another Indian Bud dub-ay keshig became blind and has not since recovered his sight. He is still living at Mille Lac. Minn. The others although very sick. recovered without any bad effects It was thought at the time that the death of the Indians was due to the wood alcohol in the essence of lemon C A W

Case 14—(From Dr W G Craig, Hartford, Conn)

M J, colored, aged 50, was given as a beverage a mixture of sugar, water and Columbian spirits, about three fluid ounces in all This was on April 30, 1902 The dose was followed by nausea and vomiting and in twelve hours by complete loss of vision She recovered her sight to some degree, but a month later it was only 1/8 in each eye Nerve heads chalk white

Case 15—(From Dr M M Cullom, Nashville, Tenn)

While acting as interne in the Manhattan Eye and Ear Hospital, New York City, the following case came under Dr Cullom's care

In October, 1897, a workman was brought into the hospital with the following history Two nights before he drank some wood alcohol in his room It threw him into a stupor and, as he expressed it, "When he waked it was so dark that he supposed it was still night" He groped his way out into the hall and asked some one the time and was informed that it was about 9 o'clock in the morning The following day he was brought to the hospital His pupils were widely dilated and did not respond to light He had only perception of light in both eyes The ophthalmoscope showed both nerve heads to be milk white in appearance and the entire fundus was blanched, the vessels being much smaller than normal He was put on increasing doses of strychnia nitrate, administered hypodermically, which were carried to the physiologic limit. The vision improved for a short time until with his left eye he could count fingers, but the improvement was soon lost and he was discharged as hopelessly blind There was no attempt made to secure a sample of the alcohol

Case 16—(From Dr I F Dickson, Portland, Ore)

Two teamsters, strong, healthy men, under 30 years of age, who had been working hard all night, arrived at a friend's house in the early morning, much fatigued The friend offered them a drink of something that, he said, "would make them feel better" He accordingly prepared a mixture of wood alcohol and water sweetened with syrup One man died toward evening The other took only a few mouthfuls and spat some of it out, as he did not like the taste Shortly afterward he became unconscious and remained so till next morning When he awoke he could only distinguish light, and within three weeks the sight was entirely lost About this time the discs began to show signs of atrophy, otherwise the fundi were normal He was first seen by a physician shortly after taking the drink, when it was noticed that the pupils were slightly dilated, but nothing abnormal was then seen in the background of either eye and no fundus changes appeared for about three weeks The latest report from the patient is that he is still totally blind

The following case is of great interest owing to its early occurrence (1898) It was one of the first examples of blindness due to bay rum made from Columbian spirits

Case 17—(From Dr J A Edwards, Columbia, Tenn)

In February, 1898, he was called to Centerville, a town thirty one miles distant, to see a young lawyer, W A K, aged about 26 years, who gave the following history Living in a "dry" town and being in the habit of going on periodical sprees he called on a friendly physician who was in the habit of giving him a prescription containing alcohol and any other simple drug which would protect the druggist filling it from prosecution for violation of the liquor laws On this occasion he was given, to supply the needed alcoholic beverage, as well as to protect the druggist against the provisions of the prohibition law, the following prescription

℞ Bay rum	2 fluid ounces
Alcohol	4 fluid ounces

Sig To be applied externally

He drank all this in an hour or so, and was afterward seized with violent pains in the stomach, nausea and vomiting, which continued about 24 hours, when he became totally blind Dr Edwards found him with pupils widely dilated and some tenderness of the globe on firm pressure Having obtained the above history of his case the diagnosis of retro bulbar neuritis or toxic amblyopia was made At that time very few reports of such cases had been published, but he was given an unfavorable prognosis, and was told that his vision would probably clear up in from ten to twenty days, but that blindness, either partial or complete, might recur from secondary changes in the optic nerve The patient promised to call on Dr Edwards in a few days, but saw, instead, another very competent oculist, under whose care for three or four weeks his vision cleared almost to normal Very soon thereafter his sight again declined to 20/60, with scotomata in parts of the visual field He still sees only well enough to read very large print, and that with much difficulty, on account of the scotomata. He practices his profession, but is very much handicapped, his wife being obliged to assist him in his legal work Investigation developed that the "bay rum" in this prescription with which he was poisoned, was put up by a firm in Buffalo, N Y, and made of Columbian spirits

Case 18—(From Dr W E Driver, Norfolk, Va)

J B, male, white, age 25, U S sailor, brought July 12, 1898, from the U S Naval Hospital, by the surgeon in charge He gave the following history One week since the patient and two of his companions, who were in charge of a naphtha launch, indulged freely in the wood alcohol used in starting the engine He and his companions were made desperately sick, and he became totally blind

The pupils were widely dilated, but there was no visible pathologic change in the fundus The diagnosis was wood alcohol amblyopia Treatment was potassium iodid, ten grains three times a day at first, increased doses later July 16, 1898, pupils still widely dilated Had something more than light perception in each eye Optic nerve, each eye, decidedly paler than at the previous visit July 23, 1898, decided improvement in vision of each eye Can now recognize large objects Both pupils widely dilated Eyes very bright Both optic nerves show decided pathologic changes, and very much whiter than at previous visit Dr Driver learned from the Naval Hospital that soon after the last visit to his office, the patient was discharged from the Navy and nothing further was heard of his case His two companions died during the debauch, from the effect of the intoxication

Case 19—(From Dr W E Driver, Norfolk, Va)

A H S, male, white, aged 25, came Feb 2, 1903 Referred to Dr Driver by Dr Holland of Holland, Va The patient became suddenly blind ten days before When he went to bed he could see as well as ever, on waking was totally blind Had been drunk from cider purchased from a country store.

Right eye Cornea very bright and glistening Pupil widely dilated Optic nerve pale, but no other pathologic change in fundus No light perception No reaction of pupil to light

Left Eye Cornea clear and bright Pupil widely dilated Nerve white No reaction of pupil to light

Diagnosis Wood alcohol amblyopia

Patient was sent to hospital and given potassium iodid, 10 grains three times daily, and twentieth of a grain of strychnin On February 9 vision began to return in left eye Has light perception No improvement in right eye. February 15, counts fingers one foot from left eye Light perception only in the right eye Optic nerve, each eye, decidedly paler than normal February 23 patient went home, with *no* improvement in the right eye, but counts fingers at three feet with left eye Nerve, each eye, white, bluish tint Pupils widely dilated Corneal reflex extremely bright

This man has consulted Dr Driver three times since he left the hospital the first time There has been no improvement in vision of the right eye With left eye vision is 6/200

Case 20—(From Dr William H. Dudley, Easton, Pa)

Ralph W, single, aged 30, an essence pedler, about June 15, 1903, took for a "cold," diluted with water, four ounces of what he says he bought for grain alcohol Two days later his vision became very bad, and when seen three months later his optic discs were quite white, fields were narrow vision 1/200 right and left Seven months later his condition remained practically the same Patient states that as soon as he had drunk the alcohol he discovered his mistake, realizing then that he had taken wood alcohol

CASE 21—(From Dr H P Engle, Newton, Iowa.) G F of Mingo, Iowa, aged 45, drank at least half a pint of Columbian spirits diluted He lived forty eight hours, but before death there were present gastrointestinal irritation, blindness, delirium and collapse

CASES 22, 23 and 24—(From Dr W H Ford, Sulphur, Ind Ter)

As detailed elsewhere in this report, four men, aged from 30 to 40 years, went on a spree with methylated bay rum Two, who consumed large quantities of the poisonous perfume, died There is no history of blindness in one case, but the other, S B B, age 24, who succumbed to the poison, lived about eighteen hours, and suffered the most excruciating pain in stomach and bowels Even though heroic doses of morphin, administered hypodermically, were given him he had to be held in bed He was totally blind most of this time About an hour before death his pulse became imperceptible at the wrist, his heart being very rapid all the time The odor of methyl alcohol was very noticeable in the perspiration, which was very profuse The two that survived, aged 20 and 37, suffered for some twelve to fourteen days with marked ocular disturbances Vision was very indistinct, it seemed at times as if they were 'looking through a moving screen" Again, in a few hours there would be a total loss of the outlines of objects After two weeks vision appeared to return

CASE 25—(From Dr P G Goldsmith Belleville, Ont, and Dr Sprague Stirling, Ont, and from the *North Hastings Reporter*, June 15, 1904)

William Sutherland of Monteagle met his death under very distressing circumstances on Monday night He had returned from working with the chemical company near Orillia and brought a bottle of wood alcohol with him to let his neighbors see it Not suspecting its poisonous nature he let some of them taste it Finding it too strong, they were all satisfied with merely tasting it But Sutherland, it is estimated, took about a wineglassful In a short time he complained of difficulty in breathing, then of blindness, and asked for a physician, who was sent for He soon lapsed into unconsciousness and died before medical aid could arrive Deceased was a respectable farmer about 45 years of age, and a widower, having two sons The sad event cast a gloom over the community

CASE 26—(From Dr A H Gordon and Dr Frank Buller, Montreal, Quebec)

B K aged 40, female domestic, alcoholic On Jan 18, 1904, had been drinking for two days Drank one quart of whiskey, a half pint mixture of gin and spruce gum, as well as nearly eight ounces of wood alcohol Vomited all one morning and in the afternoon became excited, partially delirious Complained of severe headache, pain in arms and fell to floor unconscious Later, general convulsion and death in half an hour after convulsion Half an hour before falling she groped about the room calling for light, evidently completely blind Pupils widely dilated and inactive The cause of death was undoubtedly the wood spirit drunk within twenty four hours of her death The autopsy showed no brain or kidney lesion

(*To be continued*)

An Aid to the Comfort of Bedridden Patients.—*American Medicine* says that in cases of severe heart disease with orthopnea it is often extremely difficult to keep the patient in the semi upright position as the direct pressure on the tuberosities of the ischium is not only uncomfortable but is conducive to bedsores, and there is also a tendency to slip down in the bed In such cases a hard bolster is placed under the mattress at the level of the thighs forming with the pillows a double inclined plane in the trough of which the back rests The support and the removal of a part of the weight from the tuber ischii to the fleshy part of the thighs affords great relief to the patient

---

FATAL POISONING DUE TO SKIN ABSORPTION OF LIQUID SHOE BLACKING (NITROBENZOL)

WITH AUTOPSY REPORT

WILLARD J STONE, B Sc, M D
TOLEDO, OHIO

A report of the clinical and autopsy findings in the following case is of interest, first, because of its rarity, it being, so far as I have been able to ascertain, the only case recorded in which the fatal result could be attributed to skin absorption of this poisonous agent, and, secondly, since it reiterates once more the danger attendant on the use of the various cheap products of coal-tar distillation as solvents for the anilin dyes in certain commercially manufactured articles

Dr A W Wheeler and Dr Peter Donnelly have kindly furnished the clinical history of the case

History—W R, aged 22, male, salesman, in excellent health so far as could be ascertained, was taken suddenly ill in a café about 12 30 a m March 20 He had attended a dancing party earlier in the evening in company with some friends After the party he and four or five of his associates went to the café for a lunch His friends were with him during the entire time after he left his room earlier in the evening He remarked while in the café that he did not feel well, but his friends noticed nothing unusual about his appearance except that he seemed very pale In the café each one drank four or five glasses of beer While standing up to put on his coat, which one of the men present was holding for him, he suddenly seemed to faint and fell to the floor He was carried into an adjoining room, and a medical student who happened to be present dashed cold water in his face, which seemed to revive him He complained of no pain, but felt dizzy and faint and shortly after vomited the beer, crackers and cheese eaten but a few moments before He was assisted to a carriage, and arrived at his room at about 2 a m

A physician was not called until about 3 30 a m, since his roommate supposed him in a drunken stupor The physician, Dr Wheeler, was informed that he had passed into the comatose condition on arrival at his room about 2 a m, and that he had not recovered from it

Examination—Dr Wheeler found him in collapse, very pale skin, eyes glazed, cyanotic lips, ears and finger tips, corneal reflexes absent, no peculiar odor to breath, no convulsive tendencies, heart action fairly good, both sounds clear, pulse rapid, 130, skipping about one beat in 25, respiration 28 His friends were unable to throw any light on the cause of his condition, except that they thought him drunk

Death—After giving 1/30 strychnin and 1/10 apomorphin, Dr Peter Donnelly was called in consultation, but shortly after his arrival (4 45), a slight convulsion occurred, and with a sudden dilatation of the left pupil the heart stopped beating (not heard by auscultation or perceptible at wrist) Slight respiratory efforts continued for about five minutes, after which the patient died, in all, about four and one half hours after the fainting attack in the café

Autopsy—This was made by me about six hours later, March 20 Length, 71 inches, weight about 160, good muscular build, no scars or deformities, no signs of trauma or surgical wounds, skin and all visible mucous surfaces very pale, ear lobes and finger tips cyanotic, hair black, both feet discolored black to above ankles, resembling the crock of black colored hose, rigor mortis just beginning in jaw, no postmortem lividity of under surfaces, slight body heat present, no distention of abdomen, no edema lower extremities

Thorax Mediastinal tissue small in amount, lymph glands normal, no fluid in pleuræ, pericardial sac not distended, fluid normal

Heart Fatty covering normal, section muscle normal color, left ventricle wall hypertrophied, 20 mm thick, mitral valve admits two fingers, valve flaps thin, normal, aortic opening admits thumb, valves normal, coronary openings patent, traced to smaller ramifications, no thrombus or embolus, right heart normal, dark fluid blood and small mixed clot in right auricle, pulmonary artery traced to small ramifications, no embolus, thoracic aorta normal

Lungs Pleuritic adhesions both lungs behind and at apices, section, old scar right apex, anthracosis moderate, dark red in color, yields slight fluid on pressure, crepitant throughout, slight hypostasis lower lobes, bronchial lymph glands negative

Abdomen Omentum and peritoneum normal Stomach Ligated cardia and pylorus—removed entire Spleen 12 by 10 cm , capsule normal, dark red on section, follicles, pulp and connective tissue normal Liver Not enlarged, brown red on section, mottled appearance in areas, consistency normal, shows cloudy swelling, parenchymatous degeneration Gall bladder and ducts Normal, no calculi Pancreas Small, otherwise normal Adrenals, Normal, small Right and left kidneys Identical in appearance, large capsules strip off readily, do not drip blood on section, though they appear congested, dark red in color, cortex paler in color, congestion (?), parenchymatous degeneration, acute nephritis (?) Ureters Patent throughout Bladder Normal, 150 c c urine withdrawn by catheter for examination Duodenum Small intestine and colon normal, serosa not injected Appendix Long, free entire length, contains small, hard concretion

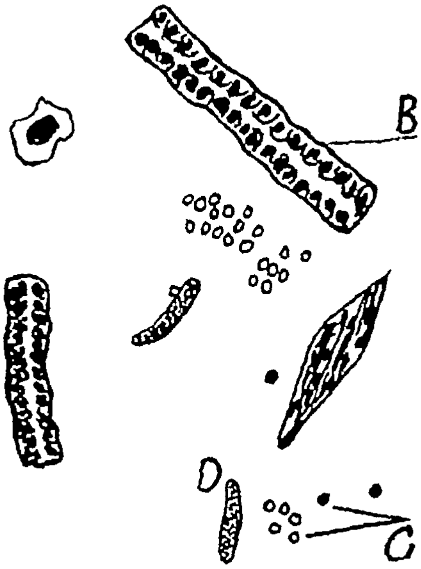


Fig 1 —Camera lucida Acute desquamative nephritis from nitrobenzol (Zeiss, oc 4 obj A A) A True epithelial cast of medium sized tubules B True epithelial cast of larger tubules C Red and white blood cells D Fine granular cast.

Brain Meningeal vessels congested Internal capsule normal Vessels traced to finer branches, no embolus or hemorrhage Ventricles normal Basal sinuses, cerebral ganglia peduncles, circle Willis, cerebellum, pons and medulla, normal

Stomach contents About 40 c c opaque, rather thick, dark red fluid Absence of free HCl to Congo red and di methyl amido azo benzol papers Sour odor Microscopically, much amorphous débris, cellulose fibers *en masse* (crossed striation), many finer cellulose particles Many fat globules, large and small, many small non motile bacilli, few shreds gastric mucosa (columnar celled), no crystals of any kind seen Negative guaiac test for blood

Urine Amount withdrawn by catheter, 150 c c , specific gravity, filtered urine, 1013, reaction, acid, heat plus HNO_3, slightly positive, acetic acid plus potass ferrocyanid, positive, Fehling's, negative, Nylander's, negative Microscopic examination Many white (see illustration), and red blood cells, many finely granular casts (medium size) many larger hyaline and leucocyte casts, few very large epithelial casts of the larger tubules (about one in every two fields with low power) bladder epithelium and spermatozoa (death phenomenon)

Microscopic examination of liver Congestion slight cloudy swelling (parenchymatous degeneration) and fatty degeneration quite general throughout sections, necrosis in areas

Microscopic examination of kidneys Stained in eosin hematoxylin and Van Gieson Cloudy swelling (parenchymatous degeneration), general throughout sections Necrosis in areas Much débris in larger tubules Partly exfoliated epithelial lining of tubules in many areas

Diagnosis —Acute desquamative nephritis and acute hepatitis (toxic?)

Etiology —Subsequent inquiry four or five days later into the circumstances surrounding the death by the coroner, Dr C Storz, revealed the following facts The young man had purchased, a few days before his death, a pair of shoes at a sale being advertised in the city These shoes were black patent leather lowers with cloth tan tops On the evening of the dance above mentioned he had applied a liquid shoe blacking, made in Chicago, to the tan cloth uppers of the shoes These shoes were worn that evening The cloth uppers absorbed enough of the blacking to entirely cover up the tan color, and, moreover, since the shoes were put on before the tops were dry, to stain his feet and ankles black

The coroner found in the man's room part of the bottle of blacking used and also the shoes Both the shoes and blacking emitted a strong odor, not unlike oil of bitter almonds, the shoes having this odor a week after death A portion of the blacking and the shoes were turned over to City Chemist G A Kirchmaier Through his kindness I am able to append his report

Chemical Examination —About three drams of liquid shoe blacking was received from the coroner Suspecting nitrobenzol from the odor, the blacking was distilled after adding H_2SO_4, according to the method of Jacquemin[1] To the distillate zinc and H_2SO_4 was added to reduce to anilin, after which the liquid was treated with excess of sodium carbonate and filtered On the addition of a drop of carbolic acid and then some sodium hypochlorite a brown coloration, rapidly changing to blue, appeared, due to formation of sodium erytrophenate, and which indicated the presence of nitrobenzol The amount of pure nitrobenzol obtained was nearly as much as the total amount of blacking received from the coroner The shoe tops were also extracted with solvents and marked traces of nitrobenzol obtained

Reinsch's test for poisonous metallic salts was applied to stomach contents with negative results

Nitrobenzin (or nitrobenzol $C_6H_5NO_2$) was discovered by Mitscherlich in 1834 Casper,[2] cited by Blyth, first called attention to its poisonous properties Its importance as a commercially used article lies in the fact that it is a cheap solvent for the various anilin dyes and that it is used as a flavoring or odoriferous agent, under the name "Essence de Mirbane," in cheap perfumes soaps and confections Nitrobenzol is an intermediate product between benzin a constituent of coal-tar, and anilin It is in reality formed from the action of nitric acid on benzin ($C_6H_6+HNO_3=C_6H_5NO_2+H_2O$) and anilin the next step in the process, is formed direct from nitrobenzol (Allen[3] and Lloyd[4])

Pure nitrobenzol is a pale yellow liquid, having an odor closely resembling that of the essential oil of bitter almonds It differs, however, from that body in many respects the oil of bitter almonds being benzoic aldehyd (C_7H_6O)

SYMPTOMS

Jubell[5] collected, between 1848 and 1876 42 cases of poisoning by nitrobenzol 13 of which were fatal R

Bachfeld,[6] cited by Gould,[7] has collected 63 poisoning cases by anilins and benzols. He concludes that there is danger of poisoning if clothing soaked with anilin or nitrobenzol remains in contact with the body. Nitrobenzol is a powerful narcotic poison, whether taken in the form of vapor or as a liquid. The fatal dose for an adult is probably about 1 gram, although numerous examples exist of serious poisoning by much smaller doses. The quantity which would be fatal if breathed is not known with any accuracy. Husemann[8] mentions several cases of poisoning associated with the symptoms stated by the various authors mentioned as common to all: 1, fainting; 2, cyanosis, and 3, coma. A case cited by Taylor[9] is typical:

> A woman tasted a liquid used for flavoring pastry (it was afterward chemically identified as pure nitrobenzol). She immediately spat it out, swallowing probably not more than a drop. In replacing the bottle about a tablespoonful was spilt. As it was a small room the vapor rapidly permeated the atmosphere in it, and caused illness in herself as well as in a fellow servant. In about three hours, when seen by a physician, she showed symptoms of prussic acid poisoning. The features were pale and ghastly, skin clammy, lips and nails cyanotic, pulse feeble but mind clear. She became suddenly unconscious a few moments later, consciousness returning in eleven hours. Recovery not complete for weeks.

This case is exceptional, since recovery in instances where coma has developed is very rare.

Blyth[10] states that the symptoms are almost identical with prussic acid poisoning, except that in nitrobenzol poisoning there is a much longer interval between taking the poison and its effects. "This is, indeed, the strangest phenomenon of nitrobenzol poisoning, for the person taking it may appear well for periods varying from fifteen minutes to three hours, or even longer, and then there may be the most alarming symptoms, followed by coma and sudden death." (Note similarity to the present case, also Dr. Collamore's case below.)

Cases vary but little in their main features; in a few the blue skin and deep sleep are the only symptoms noted. This, of course, is quite typical for excessive doses of any of the coal-tar products, i. e., antipyretics, naphthalene yellow, metanil yellow, orange II or picric acid combinations. These latter have been used as constituents of butter color along with anilin yellow (dimethyl-amido-azo-benzin), and from the use of which several fatal poisoning cases have been recorded.

Nicholson[11] reported a case of fatal poisoning by liquid nitrobenzol. He stated also that the vapor from "almond glycerin soap" had caused in a friend of his who used it while taking a warm bath symptoms of mild poisoning (fainting and illness for some time afterward). It would seem that the circumstances surrounding this last case were favorable to skin absorption of the poisonous agent and that the symptoms of poisoning which followed could be attributed to absorption in such a way.

Dr. G. A. Collamore, Toledo, about ten years ago attended a man who, when intoxicated, touched a small bottle of nitrobenzol to his lips under the impression it was whisky. The accident happened in the home of a local soap manufacturer, who had brought the stuff to the house from the factory and deposited it on the mantel because it imparted a pleasant (sic) odor to the air of the room. Shortly after, the man became unconscious and was cyanotic. After twenty-four hours he regained consciousness and insisted on returning to his work, though still cyanotic. He died suddenly while attending to work twenty-four hours later. The skin was dark colored and the breath exhaled the odor of bitter almonds.

Letheby[12] relates the case of a man who spilt some considerable quantity on his clothes. For several hours afterward he went about breathing an atmosphere of nitrobenzol. He then became drowsy, expressionless, and, with unsteady gait, presented the symptoms of intoxication. The stupor suddenly developed into coma and the man died, the fatal course being altogether nine hours, i. e., four hours before coma and five hours of total insensibility.

The first symptoms usually are headache, drowsiness, flushing of the face (which is shortly followed by extreme pallor, with cyanosis of the ears, finger-tips and lips), dyspnea (not present in the case under consideration), dilation of pupils, loss of voluntary power, and sometimes convulsions. These symptoms are followed by coma, which usually appears suddenly and increases in intensity till death ensues in five or six hours. When the stage of coma is reached there is but little chance of preventing a fatal termination (Allen). Death is usually stated to be due to paralysis of the respiratory centers. In the present case death was evidently caused by paralysis of the circulatory centers, since the heart stopped beating about five minutes before respiratory efforts were discontinued.

POSTMORTEM FINDINGS

It is such an insidious narcotic poison that indications pointing to severe irritative action on stomach or bowels—when swallowed—are usually absent. The kidneys and liver may show extensive parenchymatous degeneration, as in the present case, this being probably mere evidence of the attempted eliminative process on the part of these organs. The changes are, however, no different from the action of many other actively poisonous agents. When swallowed the breath may give off an odor resembling the oil of bitter almonds. Filehne[13] states that the blood gives the spectrum of acid-hematin. A dark brown to black color of the blood has been noted in some cases—the blood not being coagulated.

Cushny[14] says that the oxygen-carrying power of the hemoglobin, when combined with nitrobenzol, seems to be lost. Its carbon dioxid is also decreased. With the spectroscope methemoglobin has been found, although in two cases—not fatal—cited by Huber[15] the blood was chocolate colored, but gave in both instances normal blood and spectroscopic tests. An absorption band which does not seem to correspond to any of the usual hemoglobin products, often appearing between the yellow and red, has been noted in several cases. It has been designated the nitrobenzol-hemoglobin line.

Weyl[16] mentions that sugar is found in the urine in nitrobenzol poisoning, although in the present case (and in Huber's cases, mentioned above) no reducing substance was present which reacted to Fehling or Nylander solutions.

TREATMENT

Since death occurs from narcotic action, with subsequent paralysis of the respiratory and circulatory centers, in this as well as in poisoning with other coal-tar anilin preparations, a prompt emetic should be given or the stomach tube used The stomach tube should be used, since, as in the case of morphin, the possibility of the drug being excreted into the stomach and bowels should be borne in mind An effort should be made to ward off the impending coma, constant exercise, flaggellation with wet towels and rubbing being employed Hypodermically, atropin 1/100 to 1/60 gr and cocain 1/4 to 1/2 gr might be used for their stimulative action on the respiratory and cardiac centers Evidently the process of elimination is attempted by the kidneys (as in the present case) and possibly also by the bowels Large quantities of hot normal salt solution per rectum or intravenously would undoubtedly assist in this process The depressant action of and danger attending the use of pilocarpin to assist elimination by the skin, in cases of already depressed circulatory activity, would seem to be contraindicated because of the danger of pulmonary edema

CONCLUSIONS

This case reiterates the danger of the promiscuous use of nitrobenzol by manufacturers How they are able to prevent poisoning among the workers in their factories is somewhat of a mystery Its use should be still more strenuously prohibited as entering into the composition of liquid shoe blacking, cheap soaps, confections and similar articles of widespread usage The conditions present in this recorded case were unfortunately such as to permit of absorption by the skin The shoes were put on before the blacking was dry, and shortly afterward the exercise incident to the dancing party probably aided its absorption Nitrobenzol is probably used as a solvent for the anilin dyes in many liquid shoe-blackings on the market The reason that the small boy shoeblack is not more frequently poisoned lies in the fact that but a very small quantity of the liquid comes in contact with his fingers, brushes being used instead while the fingers are usually used for the application of the "polish" The "polish" is probably an anilin-black in most cases and probably contains nitrobenzol as a solvent Why fatal poisoning is comparatively so rare among shoe-blacks is not quite clear Perhaps but extremely small quantities are absorbed and that this absorption extends over a considerable time

SPLENECTOMY FOR SPLENIC ANEMIA

J H CARSTENS, M D

DETROIT

Splenic anemia is a distinct variety of anemia, and entirely different from the various conditions characterized by enlargement of the spleen and classified under various names The distinctive features are enlargement of the spleen without enlarged lymphatics, evidence of pigmentary deposits, and if long continued, disturbance of the liver and ascites So far as etiology is concerned nothing definite is known

The special features of the condition are 1, Slight diminution in the number of red corpuscles, 2, reduction in hemoglobin and 3, a most remarkable reduction in leucocytes This last seems to be the pathognomonic condition

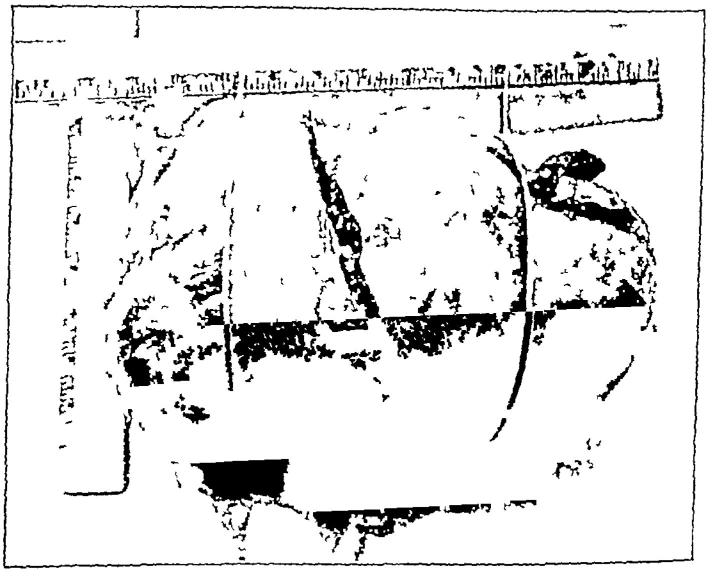
H C Wood[1] first described this in 1871 He says "I now desire to show that there is still a third form of pseudoleukemia, a splenic variety Under the names of tumor of the spleen, splenic cachexia, etc, medical records furnish accounts of cases which I believe represent this affection" Griesinger, in 1866 describes a case in a child and called it anemia splenica, although it has since been shown that enlargement of the spleen in children is different from that peculiar enlargement found in adults

Sippy has given us an excellent resume on the subject and reported in full a case which ended in death He gives all the blood examinations and careful microscopic examination of the spleen with illustrations

Osler, in two papers, reports 18 cases, some of them having extended over a period of many years, the patients being in fairly good condition Harris has also reported quite a series of cases

My case is as follows

History—Mr B, aged 38, had always been well until last winter, when his abdomen began to enlarge He became weak and pale, digestion was poor and he was unable to work Various remedies were tried without much benefit The enlargement of the abdomen increased until it reached the symphysis, crowding the abdominal viscera toward the right It was diagnosed as an enlarged spleen He was brought to me by Dr Peterson of Ruth and I had his blood examined by Dr Sill of the Detroit Clinical Laboratory The report is as follows



Spleen removed by Dr J H Carstens

Blood examination—Erythrocytes	3 804 000
Hemoglobin	75 %
Color index	0 94 %
Leucocytes	1 250
Polynuclears	10 %
Mononuclears	90 %
Eosinophiles	

There was a marked reduction in the number of leucocytes and an enormous increase in the proportion of the lymphocytes The red cells showed no degeneration

Operation—July 21 An incision was made along the outer edge of the left rectus a large incision being necessary on account of the size of the growth I found some slight adhesions of the omentum but otherwise no complication The spleen was very soft, almost like jelly In trying to lift it out of the wound I turned it a little so that the apex would come out first It broke and a severe hemorrhage occurred which was controlled by clamping the pedicle I removed the spleen ligated the blood vessels separately and then the pedicle There was one vein the size of an ordinary pencil Several bleeding points in the omentum were ligated the abdominal cavity washed out and the wound closed He was given an enema of two quarts of saline solution and put to bed

---

[1] American Journal of Medical Science

During the first few days there was a temperature varying from 99 to 101 degrees, with the pulse 120 On the 26th the temperature went higher, and a blood examination made by Dr Edmunds showed leucocytes 11,000 On the 29th temperature went up to 105 degrees, pulse 132, and the increase of leucocytes indicated sepsis

REPORTS BY DR C W EDMONDS

July 28—Reds	2 745 000
Leucocytes	11 204
Mononuclears	27 %
Polynuclears	73 %
Hemoglobin	70 %
July 29—Reds	2 019 200
Leucocytes	1 077
Mononuclears	18 %
Polynuclears	82 %
July 30—Leucocytes	4 777
Mononuclears	19 7 %
Polynuclears	80 3 %
July 31—Leucocytes	4 526
Polynuclears	85½ %
Mononuclears	14 %
Eosinophiles	½ %

August 26 I removed the dressing and examined the abdominal incision, which had been closed with sterilized catgut I found a red spot which indicated a stitch abscess This was opened and a small quantity of pus removed The leucocyte count again dropped He had been irrational for a day or two, and one night in the temporary absence of the nurse, he got up and walked around the room He was put to bed and a restraining sheet applied The next morning, during a violent effort at coughing, something gave way and on examining him I found that the edges of the abdominal wound had separated and the intestines were protruding An anesthetic was administered, the abdomen thoroughly washed out and the incision closed with silkworm gut sutures

Results—His recovery after this was rapid and uninterrupted He developed a voracious appetite, his mind became perfectly clear, and he returned home four weeks after the operation perfectly well A few days after sewing the abdomen I had another count of his blood made and the report by Dr Sill was as follows

August 1—Erythrocytes	4 128 000
Hemoglobin	60 %
Color index	0 75 %
Leucocytes	2 600
Polynuclears	77 77 %
Mononuclears	22 23 %
Eosinophiles	

In comparison with previous examination the blood showed a marked change The red cells had increased, but the hemoglobin had dropped in percentage There was an increase in the number of leucocytes with a startling change in the proportion of the varieties the polynuclears regaining their normal proportion

The spleen weighed fourteen pounds The pathologic examination of the growth made by Dr H Gibbs, is as follows

Examination of Tumor—Hyperplasia of splenic tissue without increase in the capsule or trabeculæ The whole tissue is infiltrated with blood, in some places amounting to extravasation There is no appearance of malignancy

Further blood examinations were made occasionally by Dr F Edmunds as follows

August 8—Reds	[illegible] 000
Hemoglobin	65 %
Leucocytes—	
Mononuclears	28 %
Polynuclears	71
August 12—Leucocytes	[illegible]
Polynuclears	71 1/3
Mononuclears	18 1/3
Eosinophiles	1/7
Hemoglobin	70 %

The peculiarity of the blood in these cases is the very small number of leucocytes That seems to be distinctive of splenic anemia, but the most remarkable change was 10 per cent polymorphonuclears and 90 per cent mononuclears before he was operated on, while ten days after the operation the proportion was nearly normal

In order to throw more light on the subject I asked him to come for another blood examination He came and eight months after the operation the blood report, by Dr Joseph Sill, is as follows

Date received April 5—Erythrocytes	5 448 000
Hemoglobin	100 %
Color index	1 0
Leucocytes	9 250
Polymorphonuclears	58
Mononuclears	42 %
Eosinophiles	

This specimen of blood was practically normal

Beside this the man's appearance was remarkably improved I did not have him weighed when he arrived at the hospital but when he left he weighed 97 pounds, and the day the last blood examination was made he weighed 193 pounds, was the picture of health and in every way well, except having a slight bulging at the line of incision, and hence was incapacitated for hard physical labor

SUMMARY

1 Splenic anemia is a distinct variety of enlargement of the spleen

2 It can be diagnosticated by blood count, which shows an abnormal and small number of leucocytes It is, as a rule, slow in its development, and is but slightly relieved or retarded by treatment

3 Splenectomy seems to offer the only chance for a permanent cure

---

X-RAY THERAPY IN LEUKEMIA

A PRELIMINARY REPORT WITH SPECIAL REFERENCE TO LYMPHATIC LEUKEMIA

JOSEPH A CAPPS, M D, AND JOSEPH F SMITH, M D, CHICAGO

EDITOR'S NOTE The article with the above title in THE JOURNAL, Sept 24, 1904, page 891, was marred by the inadvertent omission of the accompanying table The readers of the article easily recognized the fact that something was omitted, as the table was referred to in the article

CASES OF LEUKEMIA TREATED BY THE X RAY

Case No	Type	Acute or Chronic.	Effect of the X Ray on			Time of Observation under X Ray	Present Condition
			Spleen	Glands	Leucocytes		
1*	Spleno-Myelogenic	Chronic	Enormous mass reduced to small size Recurrence	None	261,000 to 10 000 Recurrence 230,000 to 9,400	18 months	Dead
2	Spleno-Myelogenic	Chronic.	Much reduced	None	409 000 to 46,500	12 weeks	Improved
3	Lymphatic	Subacute	Much reduced	Reduced nearly to normal size	70,500 to 25 000	10 months	Dead
4	Lymphatic	Subacute	Not noticeable	Not noticeable	80,000 to 64 500	6 weeks	Dead
5	Lymphatic	Acute	Not noticeable	Not noticeable	69 000 to 299 000	10 days	Dead
6	Lymphatic	Chronic	Reduced	Much reduced	208,000 to 48,300	16 months	Dead
7	Lymphatic	Chronic	Reduced	Much reduced	150 000 to 4,200	5 months	Improving
8	Lymphatic	Chronic	Reduced nearly to normal size	Reduced nearly to normal size	295 000 to 6,800	8 months	Improving

*Case previously reported by Dr Senn

THE VALUE OF CYTODIAGNOSIS IN DISEASE OF THE CENTRAL NERVOUS SYSTEM

During the last two years a number of articles have appeared, particularly in journals devoted to neurology, dealing with the so-called cytodiagnosis. This procedure, which is a natural outgrowth of the differential blood count, consists of a differential count of the cells in an inflammatory exudate, or in one of the natural secretions of the body, as the cerebrospinal fluid. The introduction of a test of this sort is almost invariably followed by a certain number of articles based on an insufficient number or an insufficient variety of cases, and as a result of this false though often very attractive conclusions are reached, and too many of us are too apt to accept the various claims set forth for new methods without the necessary saline flavoring.

In the case of cytodiagnosis, the most work has been done on the central nervous system by staining centrifugalized cerebrospinal fluid withdrawn by lumbar puncture. It is in diseases of the central nervous system that the procedure has been claimed to be of the greatest value. The main claims, briefly stated, of the majority of French, German and American writers, have been that an increase in the lymphocytes in the cerebrospinal fluid is pathognomonic of a meningeal irritation and that such an increase is characteristic of the early stages of general paresis and tabes dorsalis and of cerebrospinal syphilis.

In a recent article,[1] Niedner and Mamlock have drawn attention to some of the fallacies which are apparent in the technic and in the interpretation of the results of cytodiagnosis as it is now done. As these observers point out, if we are to compare the results of different workers with a test of this sort it is necessary to base all observations on a common technic, and so far this has not been done. A measured quantity of the fluid should be taken, it should be centrifugalized in a centrifuge having a given number of revolutions per minute, and should be left in the centrifuge for a given length of time. Further, the method of making spreads, and the method of staining should be uniform, and the technic as a whole should be as simple as possible. The present lack of uniformity of technic makes it difficult if not impossible to compare the results of different authors, and leads different observers to give different figures as normal. Thus French observers state that three or four lymphocytes in a microscopic field with a magnification of 400 diameters represent the normal, while certain German observers, as Merzbacher, state that under similar circumstances six to eight lymphocytes in the field are normal.

Up to the present the common conditions in which an increase of the lymphocytes in the cerebrospinal fluid has been observed have been general paresis, tabes, and syphilis of the nervous system. Occasionally such an increase has been found in other conditions, as herpes zoster, sciatica and parotitis. On the other hand, it has generally been stated that in functional neuroses, epilepsy, senile hemiplegia, cerebral tumor and compression myelitis no increase in the lymphocytes takes place. Niedner and Mamlock studied a large series of cases from von Leyden's clinic to determine whether they could substantiate the reported findings. They conclude that an increase of lymphocytes in the cerebrospinal fluid is not necessarily associated with parasyphilitic affections (tabes, general paresis), but that it may be due to any cause producing sufficient irritation of the meninges which lasts a certain length of time. Thus it may be due to intoxications (lues, uremia, tetanus), or to mechanical irritation from tumors or other mechanical factors causing cerebral pressure.

Simple irritation of the meninges from injury or disturbances of the circulation is not in itself sufficient to cause an increase in the lymphocytes. As to the value of the test, the authors state that they feel somewhat disappointed. The frequent appearance of lymphocytosis in lues, and its not infrequent absence in tabes, make its value in the latter disease rather problematical. While the test may be of some value in general paresis, as the lymphocytosis here is quite constant, still the diagnosis in these cases is so seldom in doubt that the test is rather a superfluity than an aid. The impression received by the work of Niedner and Mamlock is that the test has been very much overrated in the articles so far written.

PSYCHOPATHIC HOSPITALS AND CLINICS

One of the disadvantages with which American alienists have had to contend in the past has been the inability to study and treat the acute insane and milder grades of psychoneuroses under such advantageous conditions as the surgeon and physician enjoy in caring for medical and surgical cases in city hospitals. The acute insane are sent to large state asylums as soon as legal commitment is possible, and the psychoneuroses have never been properly provided for in city clinics. They are not admitted to general medical and surgical hospitals. Strangely enough, they are not often regarded by the admitting authorities as sufficiently ill to require hospital treatment. American cities have as yet provided no special hospital for the proper care of neurologic cases other than a few infirmaries in connection with almshouses The usefulness, even of such provisions, has obviously been sacrificed by the nature of the associations and surroundings of such hospitals

---

[1] Zeitschrift für klin. Med., vol. liv, Nos. 1, 2.

However, it looks more promising for the future Ann Arbor and Albany already have their psychopathic wards The last New York legislature appropriated several thousand dollars for a psychopathic hospital for New York City, and plans of construction are now in preparation It is interesting to note with what singleness of purpose well-meaning reformers put in operation the state care of the insane They seem to have entirely overlooked the various economic, therapeutic and scientific principles which were sacrificed in transporting all the insane from the towns and cities into large and only too often inaccessible country district asylums On the continent of Europe the mistake of caring for the insane so far from their homes was recognized early and was in process of correction long before the state-care movement had become at all general in this country Thus in the early sixties Griesinger pointed out the urgent necessity of forming small city hospitals and out-clinics for reception and treatment of the acute insane, to supplement the workings of the large district asylums for the chronic cases which were situated quite remote from the populous centers Its general adoption soon followed Germany preceded us therefore by at least two decades in establishing this type of hospital for the acute insane and psychoneuropathic

Out-clinics or dispensaries have been in successful operation for several years in the German psychopathic hospitals, indeed, the great majority of the so-called functional neuroses, such as hysterias epilepsies, chronic neurasthenics and the like, have been treated in this manner Their ratio in the psychopathic hospitals at Giessen and Kiel has steadily increased In the first year's opening of the hospital at Giessen in 1896, 6 5 per cent of the total number treated in the dispensary and wards were of the psychoneuropathic class In five years it increased to 23 per cent

In this country the lack of proper facilities for diagnosis and treatment of such cases in general neurologic clinics has often been commented on Clark and Montgomery[1] have included these essential out-clinic departments in their suggested plans for psychopathic hospitals in American cities They have arranged ample out-clinic provisions for diagnosis and treatment by electricity, hydropathy, mechanicotherapy, massage and systematized movements Out-clinics of this kind would be of inestimable value for selection of proper cases for in-ward treatment They would reduce the fear with which the general public regards such hospitals They would also result in lessening the necessity for so many private sanatoria which, for economic reasons at least, are only too often impossible for the poor

THE PASSING OF PRIMITIVE MAN

The disappearance of primitive man before civilization has been recently discussed in an interesting manner by Dr F A Cook[1] He says that alcohol and venereal diseases have been largely credited with the result, a conclusion which he questions, though he admits his observation has been limited to the sub-Polar races, the Fuegians Patagonians, Eskimos and sub-Arctic Indians He is inclined to credit as an important factor the lack of immunity of these races to the diseases of civilization which, to civilized man, have, from long familiarity, become comparatively innocuous The part played by such disorders as measles, mumps, whooping cough and scarlet fever in the destruction of primitive man, was to him a great surprise Even chicken-pox is a fatal epidemic among the Eskimos, and even more severe among adults than among children The infant mortality among the Indians is very great and this he attributes to the introduction of new diseases by explorers, traders and missionaries Alcohol and venereal diseases come second Lastly, he considers the destruction of savage ambition and altered conditions of life and environment as important factors leading to physical degeneration, and making the savages ready subjects for tuberculosis

There is undoubtedly considerable truth in these conclusions They may certainly be accepted as the deductions of a careful and trained observer in a comparatively limited field Many will think that he underestimates the influence of alcohol as a cause of degeneration and fatality There would be little difficulty in exterminating many native tribes by free trade in intoxicants during their hunting season with the consequent results of improvidence and later famine Such a condition of affairs occurred some years ago on St Lawrence Island There is undoubtedly a great deal of truth in his theory of lack of immunity, and this would be an interesting study could it be taken up over a wider field by competent observers If we could exterminate tuberculosis for many generations and then admit the infection, we might have a similar experience of our own

The influence of changed environment and of contact with a higher grade of civilization generally, unattended by a higher grade of morals is also probably underestimated by many observers We can imagine, perhaps, a similar demoralization occurring in our own race were the presence of a vastly superior class of beings without moral restraint suddenly thrust on us Mr Wells' fantasy of the "War of the Worlds," even without the active extermination he portrays, would probably soon be more than realized There is a vast difference, however, as regards racial vitality in uncivilized man, and, in some sections, with special conditions, primitive man is capable of existing and even flourishing in spite of the demoralization and disease introduced by contact with the whites Thus in the tropics the partial immunity toward malaria of some of the colored races is apparently an adequate defense, and among the Eskimos we might look for a similar partial immunity to evils of crowding and non-ventilation This may account for the fact reported by Nansen, who has observed that while tuberculosis is not uncommon among the semi-civilized Greenland Eskimo, it is by no means always a rapidly fatal disease with them, but may exist in a readily recognizable form for years without seriously interfering with their ordinary activities and pursuits, and this notwithstanding the exposure that these involve

---

[1] Suggestions and Plans for Psychopathic Wards, Pavilions and Hospitals for American Cities, by L. Pierce Clark and H P Alan Montgomery American Journal of Insanity vol lxi No 1 1904

[1] Brooklyn Medical Journal September 1904

Primitive man, however, is rapidly disappearing under all these causes and unfavorable conditions that have been mentioned, together with many others, in most parts of the world The desirability of careful medical studies among primitive people is, therefore, the more imperative There is a field of study here which has been too much neglected, and in many cases the opportunity is forever lost It is to be hoped that medical explorers and even non-medical ones will give it their future attention It may be that such a study thoroughly carried out would lead to some valuable practical deductions as regards the warding off of disease among civilized races as well

---

THE GROWING NECESSITY OF COLLEGE TRAINING PREPARATORY TO MEDICAL STUDY

For the young man who is planning to fit himself for the practice of medicine there are two possible routes One, the longer but admitted by all to be more nearly the ideal, involves the intervention of a greater or less length of time between the completion of the high-school course and the actual assumption of medical study, to be spent in attendance at some college or university, the other is the short cut from high school to medical school, which is recognized as practical by a large number of eminently well-conducted medical schools, although their number is steadily decreasing There can hardly be a question as to which is the better route The question that does arise in the minds of many is, however, does it pay to give up from two to four years to college work which, in large part, may have no direct bearing on the study or practice of medicine?

There are two things that are to be obtained in a college course One is the acquisition of certain knowledge, and this is, perhaps what the majority of people consider the chief function of any educational institution The other is the social training, the habit of contact with people of rather better than average bearing and education the broadening of prospect, and the development of ideals, and it is these less material profits of college education that those most familiar with the subject will insist are really the most important In the nature of things a medical school must be given over almost entirely to the first matter—the imparting of information The curriculum of every school is so crowded that there is little opportunity for anything but hard work, and the student's mind has little time for play on any but the topics of his work The hours for social contact are few, the instruction afforded is essentially narrowing, and the desire for hospital appointments and other immediate rewards holds the attention of the student fast on the one subject The intensity of concentration and the eagerness for new information that is so characteristic of the medical student is brought out very strongly in those institutions in which medical and undergraduate students occupy the same buildings and grounds Therefore, the medical student seldom gets much social advantage from contact with his fellow-students, and still less from the faculty, as a rule, and the student who has entered medical work in the immature condition of the high-school boy is bound to lose altogether this benefit that is conferred so well by the college To be sure, there are some of the most broad-minded, cultured and estimable of the members of our profession who have had never a moment of undergraduate life in their career—some who have not even had a high-school education but these are brilliant exceptions Most of us must get our polish through contact Furthermore, it will be generally found that these are the very men who regret the lack of a college education most of all With the rapid increase in the number of colleges and universities throughout the country, and the great growth among them all, the proportion of college-bred men and women in every community is rapidly increasing, and already they form a very considerable proportion of the generation with which the present-day medical student will live It is certain that these college-bred people holding the positions of trust and influence in their several communities, will constitute that portion of the society to which the physician will naturally look for his companionship and associations, and the mere holding of a degree and a title without the necessary breadth of education and culture behind it will not of itself make him acceptable to them Success consists of a good deal besides a large income and a professional man who is not socially recognized is seldom happy No one would be so foolish as to insist that a college education is the *sine qua non* of social and mental success, but we know of no other aid that is so great or so satisfying in after years

As for the advantages of the college training in the way of the addition of knowledge, there is much that could be said bearing on the relation of a full training in literature, economics and history to breadth of character and the formation of ideals, but there are also many other things of immediately practical nature First of all should be mentioned the study of French and German without a reading knowledge of which no student should be at the present day Then there are the fundamental conceptions of biologic science and also geology and paleontology which afford such excellent foundations for the study of human biology and development which every student needs, but which he can not possibly get elsewhere than in college But of most immediate concern to the teacher in the medical school is the training in methods of laboratory study High-school laboratory work, when it exists at all, can give little training that is of the same type as should be demanded of every medical student, and affords little conception of the real meaning of the words science and research Put together in the same laboratory two students, one of whom has had but a high-school preparation while the other has taken laboratory courses in the sciences in any good college, and the high-school student is of necessity handicapped from the start

THE DIPLOMA MILL BUSINESS

According to the newspapers, not less than 20,000 people are labeled doctors of laws letters, science or theology by diplomas bought from a young man named Farr who is in his corporate capacity half a dozen or more colleges and universities entitled to issue diplomas giving high-sounding degrees If one individual can be all this and distribute 20,000 doctorates up to date, what is the output of the numerous competitors the Buchanans the Armstrongs the Proberts and all of that ilk who are also in the business? The prospect seems to be that every fool who can spend ten dollars more or less may become a doctor of some sort or other Unearned honors coming cheaply are always in demand by a certain class Fortunately, in most of the states now there is a legal restriction on medical degrees, and imperfect as the law often is it is far better than it has been

WOOD ALCOHOL

At the session of the American Medical Association held last June the House of Delegates unanimously adopted the following preambles and resolution

WHEREAS The employment as beverages of wood spirit or methyl alcohol and its various preparations is known to have been responsible for numerous deaths and many cases of blindness in this country during the past few years and

WHEREAS, Even the breathing of confined air charged with the fumes of this form of alcohol has been shown to produce blindness, it is

Resolved That the House of Delegates of the American Medical Association recognizing the dangerous character of wood alcohol and liquors containing it, believes that it should be placed on the list of poisons It accordingly urges the proper federal and state authorities to take the necessary steps to protect life and eyesight from its pernicious influences

At the time this action was taken—on the recommendation of the Section on Ophthalmology—only a preliminary statement was ready for presentation, now, however, the investigations are complete, and we publish this week the first installment of the report of Drs Wood and Buller[1] on the subject, which confirms all that has been claimed in the preambles and resolutions To a large extent "Columbian spirits" and other "deodorized' forms of this deadly poison, wood alcohol, are being substituted for the innocuous or less injurious grain alcohol in all sorts of liquid which—legitimately or otherwise—are used by human beings These include the medicines we use, the perfumes we smell the condiments, sauces and flavors we employ in cooking, as well as the common intoxicating beverages Surely, it is high time that the medical profession should voice an emphatic protest against this wholesale poisonous adulteration of food and drink—an adulteration so far confined, by the way, to the American continent—and consider whether the sale of this 'deodorized," palatable and attractive poison should not be altogether prohibited

EXPULSION PENALTY FOR EXTORTION

A German medical society, it is reported has recently disciplined one of its members for charging extortionate fees Being consulted by an American millionaire for appendicitis, he recommended an operation and suggested the name of a surgeon The latter was employed and received a liberal fee Then the physician in question who was first consulted sent in a bill for $2,000 for his advisory services This charge was objected to and a smaller sum offered The physician then instituted legal proceedings and had the American arrested and humiliated by being placed in "jail limits"—we presume a sort of unpleasant *quasi* confinement The matter aroused public attention, and the conduct of the physician was severely condemned by press and public, and his fellow-physicians took the matter up with the result as stated It is generally admitted by the public, as well as by the profession, that a physician's charges may vary with his professional reputation, and also according to the means of his client There are high-priced physicians as well as high-priced lawyers, and nothing unethical is recognized in the distinction Moreover the scale of charges varies according to standards fixed by medical societies to fit the means of the patients Practically, there is no limit as to contracts between physician and patient One is at liberty to receive whatever the other is willing to pay, and one's conscience permits one to receive and there is nothing unprofessional or unethical in large fees *per se* When, however as in this instance, a physician attempts to force by legal means what the public would regard as extortionate demands not corresponding to what is considered the value of his services or opinions, he is liable to receive the tacit, if not the open, condemnation of most of his professional brethren The occurrence of such affairs and the concomitant public discussion is an unpleasant thing—a sort of scandal on the profession—and probably our German confrères followed the least regrettable course in the matter

NIELS R. FINSEN

In the death of Niels R Finsen in Copenhagen Denmark September 24, there passed away one of the heroic figures in modern medicine In spite of chronic and incurable disease, Finsen, with rare persistence developed phototherapy on a strictly scientific basis so that it became definitively established as a successful means of cure in lupus vulgaris He early recognized that if the great forces contained in light ever could be used in the science of practical medicine it would result only from investigations of physical, chemical and biologic nature, together with practical experiments in different diseases Apparently, his earliest publications concerning light and its action on the animal organism date from 1893 In 1896 the results of his scientific researches led to the establishment in Copenhagen, as the outcome of private and public support, of "Finsen's Medical Light Institute" Subsequently this institute, which soon became known everywhere, was greatly enlarged In 1899 Finsen began the issue of a series of reports (Meddelelser fra Finsen's medicinske Lysinstitut) in which are published the results of the scientific and practical work of the institute In the meantime there appeared important monographs by Finsen in the Danish, French and German languages Here were considered especially the rôle of the chemical rays of light in medicine and in biology and the treatment of lupus vulgaris by concentrated chemical rays The report covering the first 800 cases of lupus vulgaris treated at Finsen's institute (November 1895 to November 1901) show that 407 were cured 85 had interrupted the treatment while 308 were still under treatment This report may be taken as a model of thoroughness and exactness in dealing with matters of this kind one is particularly impressed with the carefulness to avoid premature and exaggerated statements as to the value of the method This is not the time nor the place to give any detailed account of the scientific work of Finsen and his assistants To Finsen belongs the credit of having placed phototherapy on a firm and scientific basis But no one must think for a moment that this was accomplished without persistent effort In reading Finsen's writings and the publications of others working in his institute one at once finds the keynote to be continuous extension of our knowledge of the action of light on living matter and improvements in the practical application of the chemically active rays Finsen was ever conservative in his own estimation of the therapeutic powers of light and advanced claims which subsequently proved to be without adequate foundation In his short but fruitful career Finsen consistently illustrated that unselfishness and modesty which medical men love to see in their best types He cared not for personal gain When he was awarded the Nobel prize in medicine in December, 1903 he generously turned the money received over to the use of the institute From whatever side we look at Finsen and his work, there comes only the impression of a noble character

Medical News.

CALIFORNIA

Donation for Hospital—The Pasadena Hospital has recently received an anonymous donation of $15,000 to be applied to the construction of a new hospital building

New Buildings for Sanatorium—Work has been commenced on a two story building and a bungalow cottage to cost $30 000 for the Southern California Sanatorium for Nervous Diseases Pasadena

Angelus Hospital Association Will Build—A permit was issued September 16 to the Angelus Hospital Association for the construction of two fireproof hospital buildings in Los Angeles, to cost $150,000

One-fifth of Deaths Preventable—In the last two years, 28,000 deaths have occurred in the state, of which 5,798, or more than one fifth, were from preventable diseases, and especially typhoid fever No case of plague has been reported since February

Personal—Dr Frank S Woolsey, Berkley, has been appointed physician of Alameda County, vice Dr Hubert N Rowell, resigned ——Dr Dwight H Trowbridge, Fresno, has returned from Europe ——Dr Rae Felt, Eureka, was injured in a wreck on the New York Central Railway at Lyons, N Y, September 25 ——Dr James H Todd has been re elected president of the Oakland Board of Health

Restrictions of State Health Board—Dr Newel K. Foster, Sacramento, secretary of the State Board of Health, in his report to the governor, says that while the law imposes important duties on the board, it bestows little power, as it does not oblige local boards of health to answer interrogations from the state board, does not allow enforcement of proper measures to protect life and health, gives no means for eradicating causes of diseases and epidemics or for the dissemination of information to the people save through the good will of the press

CONNECTICUT

Bequest—By the will of the late Mrs Ruth Ann Adkins of Winsted, the residue of the estate, after the payment of legacies, is devised to the Litchfield County Hospital The value of the bequest is about $15,000

Infectious diseases were reported during August as follows Measles, 15 cases in 7 localities, scarlet fever, 44 cases in 17 localities, cerebrospinal fever, one case, diphtheria, 86 cases in 22 localities whooping cough, 6 cases in 3 localities, typhoid fever, 173 cases in 47 localities, and consumption, 18 cases in 6 localities

Personal—Dr Edward S Brackett Hartford, has been appointed surgeon of the schoolship *Philadelphia,* which is about to take a trip round the world—Dr Franklin H Mayberry, East Hartford, has been nominated for state senator ——Dr L Z Skinner, Windsor, has been appointed assistant professor of anatomy in the medical department of the University of Illinois

August Deaths.—During August 1,362 deaths were reported, 46 less than in the preceding month, 33 less than in August, 1903, and 53 less than the average of August for the five years preceding This is equivalent to an annual mortality of 17 per 1,000 The principal causes of death were diarrhea, 361, diseases of nervous system, 136, consumption, 123, heart disease, 104, and violence, 86

GEORGIA.

Personal—Dr Thomas H Hall has been elected city physician of Dublin

Journals Consolidated—The editor of *Southern Medicine* announces the consolidation of that journal with *Gaillard's Medical Journal,* beginning with the October issue

Health Department Appropriation.—Augusta has appropriated an additional sum of $2,400 for the health department, $1,200 of which is to be used in betterment of the isolation hospital

National Guard Surgeons to National Meeting—The governor has detailed the surgeon general, Col Joseph A Gunn, Conyers, Majors Floyd W McRae, Atlanta, Joseph G Jarrell, Savannah, Olin H Weaver Macon, Charles J Montgomery, Augusta, and Andrew H Hilsman, Albany, and Lieutenants James M Kelly, Griffin, Guy Chappell, Dawson, John M Spence, Camilla, and Sam H Greene, Atlanta, as delegates to the Association of Military Surgeons of the United States, which meets in St Louis, October 10 to 15

IDAHO

Society Meets—The South Idaho District Medical Society met at Idaho Falls, July 2

Hospital at Coeur d'Alene—Plans are nearly completed for a hospital building to be erected at Coeur d'Alene lake on the water front, by Dr W W Webb

Smallpox Death—A patient who had been ill with smallpox for two weeks at Mahon's Mill on Lake Creek, died, principally, it is said, from want of proper care and attention

In Prison for Shooting—Dr James W S Emerson, Milner, has been sentenced to two years' imprisonment in the state penitentiary for shooting and seriously wounding his wife last autumn

ILLINOIS

Hospital Incorporated.—Baptist Hospital, Woodstock, has been incorporated, with a capital stock of $10,000

Personal.—Dr Howard Kelly, Baltimore, was the guest of honor at a dinner in Peoria, September 22 at which Dr Clifford N Collins presided——Dr Elijah A Morgan, Decatur, has retired from practice on account of ill health

Hospital Planned for Oak Park.—A hospital "built by Oak Park people and managed by Oak Park people for Oak Park people" is planned Dr John W Tope is the chairman of the incorporation committee The projectors expect to erect a building to cost $125 000, with separate isolated and maternity buildings

Illinois Suitable for Consumption Cure—The Illinois State Board of Health has issued a third revised edition of its circular on the "Cause and Prevention of Consumption," which was published in July In this circular Illinois is commended as a suitable place for the treatment of consumption, and attention is directed to climatic conditions, elevation and soil, which is equally as good as, and in some instances superior to those found at the famed tuberculosis sanatoria of Massachusetts New York and Pennsylvania The sections on the care of the consumptive, prevention of consumption, and consumption in schools, contain much new information Within the last few weeks $16,000 has been offered to the board to be utilized in the construction of a consumptive hospital

Chicago

Bequests to Hospitals—By the will of Mrs Elizabeth G Kelly the Home for Incurables receives $60 000 the Presbyterian Hospital $25 000 and St Luke's Hospital a liberal sum, the amount of which is not yet announced

Personal.—Dr George F Butler has severed his connection with Alma Sanitarium and will resume practice in Chicago ——Dr John L. Sweeny has returned from Europe——Dr and Mrs Daniel R. Brower have returned from the west——Dr Norval H Pierce has returned from a summer in Europe

Mortality for the Week.—In the week ended September 24, 457 deaths were reported, 14 more than in the previous week and 41 less than in the corresponding week of 1903 This is equivalent to an annual death rate of 12 36 per 1,000 Acute intestinal diseases caused 81 deaths consumption 63 violence 42 heart disease and Bright's disease each 34 and pneumonia 32

Antitoxin Stations Opened—The department of health has established antitoxin stations at 7 drug stores on the north side 14 on the south side, and 10 on the west side, at which diphtheria antitoxin can be obtained at the following prices 1 000 units 75 cents 2,000 units $1 25, 3 000 units $2 25 The department supplies culture outfits and makes a diagnosis of diphtheria free for all physicians who apply They advise all physicians to make a culture and send it to the laboratory in every case of "sore throat" whether they suspect diphtheria or not "because it is well known that it is practically impossible to diagnose diphtheria clinically in every case If a child dies of diphtheria one of two parties is directly responsible—either the parents in not calling in a physician soon enough or the physician for not making the correct diagnosis and giving antitoxin early enough in the disease"

Summary of Smallpox in Chicago—During the last six years 1 241 cases of smallpox have been sent to the Chicago Isolation Hospital Of these 1,114 never had been vaccinated, 127 had some sort of a scar said to have been of a vaccination in early life None of these with the old marks had ever been revaccinated Three experienced physicians examined these persons for evidence of vaccination and the figures are absolutely reliable These 1 114 cases came from the remnant of unvaccinated persons It is probable that 90 per cent of the people of Chicago are vaccinated and from this source came only 127 cases while from the remaining 10 per cent 1 114 cases were sent to the hospital Last year 389 patients with smallpox were sent to the hospital, 102 of whom were unvaccinated children under the school age of 6 years 14 of whom died This year, out of 161 cases 52 are unvaccinated children under the school age The children under school age are not required by law to be vaccinated, which accounts for these babies falling victims to this face scarring and death dealing disease The unvaccinated children under 6 years of age and the unvaccinated new arrivals in the city who have found employment without being required to produce a certificate of vaccination, furnished nearly all the victims The disease has changed recently to a more virulent form, four deaths having occurred in the last fifteen days There were but three deaths in the previous eight months Evidence that no recently vaccinated person ever contracts smallpox is the fact that during the last six years the most recently vaccinated person to be sent to the hospital with smallpox had an imperfect mark made thirteen years previous to the attack

MARYLAND

Baltimore

Opening of New Surgical Building—The new surgical building of Johns Hopkins Hospital will be dedicated with elaborate ceremonies October 5

College Opens—The twenty fourth annual course of instruction at Baltimore Medical College was opened, September 20, with an address by Dr George Reuling

Teachers to Examine Children—The board of commissioners has instructed the teachers to examine the arms of all children under them for vaccination marks and report to the health department

Need Isolation Hospital—A fatal case of diphtheria, in which a woman was without medical attendance for a week, and was dependent on her neighbors for sustenance, again emphasizes the need of a hospital for infectious diseases

Personal.—Dr William Lee Howard has returned from abroad——Drs Isaac E Emerson and Smith Hollis McKim arrived home from Europe September 18——Dr and Mrs Charles Whittier Young will sail October 25, from San Francisco, for China, where Dr Young will be a medical missionary

Defects in State Lunacy Laws—Attention is drawn to numerous defects in the lunacy laws of Maryland Dr Preston, secretary of the lunacy commission says the law is unconstitutional All that is necessary to commit any one to an asylum is the signature of two physicians to a certificate of insanity There is no identification of the signers, no affidavit is required "It would be an easy matter for a person to procure a blank certificate and forge the signatures of two reputable physicians to it, or he need not do that, but simply inscribe 'M.D' after any name I know of no instance in which this has been done, but the mere fact that it is possible under the present law is sufficient warrant for an amendment to the law" Again, the law says a person so committed "shall be confined until released by due process of law," which is legally imprisonment for life, as there is no process of law in the Maryland statute books by which an insane person can be released. The commission has endeavored to get around this by "paroling" patients who have recovered, but there is no legal warrant for it, as there should be The last legislature passed a bill by which the state, in January, 1909, will assume the care of all insane institutions, except those in private asylums By this law all pauper lunatics will be removed from county jails and almshouses to one of the state asylums Dr Preston proposes that commitment shall be made only on an order from a court of record The judge is to order an inquiry to be made into the alleged insanity by two competent physicians If they find insanity present they shall certify so under oath, after which the finding is to be approved by the judge, who, if he thinks proper, may order a new examination by physicians or jury, or may summon the parties before him In case of emergency a patient may be admitted to an institution for three days, during which the examination is to be made as above The secrecy with which the incarceration of an alleged insane person is permitted under the present statute is further said to be one of the weightiest arguments against the law, as it practically legalized kidnapping

MINNESOTA.

Ames May Go Free—The county attorney of Hennepin County has made a motion for a nolle of the ten indictments against Dr Albert A Ames, formerly mayor of Minneapolis

August Vital Statistics of Duluth.—During the month 72 deaths and 114 births were reported Typhoid fever caused 5 deaths, tuberculosis, 6, and violence, 16 No death from contagious disease was reported.

Anti-Spitting Crusade Extended.—The health commissioner of Minneapolis, after having conducted a successful campaign against spitting on sidewalks, has now caused to be placed in the galleries of all the theaters of the city huge placards reading, "Don't Spit on the Floor Fine, $5"

Hospital Notes.—The new emergency hospital at the state fair grounds, secured by the efforts of the Woman's Medical Society of Minneapolis, contains 3 wards, an operating room and several private rooms——A thoroughly equipped hospital was recently opened at Cass Lake——Work on the State Sanatorium for Consumptives at Walker will be begun soon During 1904 and 1905, $25,000 is available for the sanatorium

NEW YORK

Medical Staff Changes in Utica—At the quarterly meeting of the medical staff of Utica General Hospital, Dr Raymond L Baker was elected a member, vice Dr Thomas J Bergen, resigned

Medical Colleges Open—The medical department of the University of Buffalo opened for the session of 1904 05 September 26——Albany Medical College reopened September 20 Dr Richard M Pearce delivered the introductory address

For Nassau Hospital—A charity fair was held at the home of Mr and Mrs Clarence Mackay at Roslyn for the benefit of Nassau Hospital Mrs Mackay has recently presented this hospital with a new ambulance complete in every detail and also with a home for nurses

Faculty Changes—The following faculty changes in Albany Medical College have occurred Dr Richard Mills Pearce has succeeded Dr George Blumer as professor of bacteriology and pathology, Dr H Judson Lipes has been made clinical professor of obstetrics, Dr Spencer L Dawes, adjunct professor of materia medica, Dr Wilfred S Hale, demonstrator of anatomy and assistant curator of the museum, Dr Edwin McD Stanton, lecturer on histology, Dr Howard E Lomax, instructor in anatomy, Dr Charles K Winne, Jr, instructor in bacteriology, Dr George G Lempe, instructor in anatomy, Dr Donald Boyd, demonstrator in anatomy of the nervous system, Dr Edward F Sibley, instructor in clinical microscopy, and Dr Silas L Filkins, prosector of anatomy

Buffalo

Mercy Hospital Opened.—The new Mercy Hospital was opened with appropriate ceremonies September 24 Bishop Cotton made an address

Returned—Dr W Harry Glenny has returned from Muskoka——Drs George W York and Charles H Stadlinger have returned from California——Dr James W Putnam has returned from St Louis——Dr Bernard Bartow has returned from Wanakah

Crusade Against Insanitary Bakeries.—Health Commissioner Greene has started a crusade which has for its object the bringing of every bakery in the city into a sanitary condition Hereafter every baker will be required to obtain a permit from the health department before securing a license from the mayor This will bring the bakeries under direct supervision of the health department and the department will thoroughly inspect the bakeshops at regular intervals

New York City

Dinner to Semon—Invitations have been issued to a dinner to be given by the Section on Laryngology of the New York Academy of Medicine on November 1 to Sir Felix Semon of London

Contagious Diseases.—There were reported to the sanitary bureau for the week ended September 24, 305 cases of tuberculosis, with 145 deaths, 224 cases of diphtheria, with 16 deaths, 93 cases of typhoid fever, with 21 deaths, 58 cases of scarlet fever, with 4 deaths, 43 cases of measles, with 4 deaths, 2 cases of smallpox, 3 of varicella, and 19 deaths from cerebro spinal meningitis

Protest Against Carbolic Acid Ordinance—Health Commissioner Darlington has given a hearing to a number of druggists on their protest against the new ordinance forbidding the sale of carbolic acid in other than a weak solution without prescription The druggists claim that it would not lessen the number of suicides, as such persons would seek some other remedy, and that the five per cent solution would be as deadly in effect if it were taken in sufficient quantity Dr Darlington declared that his investigations of carbolic acid suicides for the past several months showed that in 42 per cent of the cases the acid was procured in drug stores without any difficulty

OHIO

Dr Scott Stricken—Dr Xenophon C Scott, Cleveland, was stricken with apoplexy while making a professional call, September 15, and is in a serious condition

Hyndman's Successor—Dr Albert V Phelps has been chosen to succeed the late Dr James G Hyndman as secretary of the faculty of Ohio Medical College, Cincinnati

Memorial to Dr Buechner—The Mahoning County Medical Society devoted its meeting of September 20 to a consideration of the life of its late honored member, Dr William L Buechner, Youngstown

Personal—Dr Amanda H Miller, Cleveland, has returned from Europe——Dr John P Kenny, Youngstown, is ill with diphtheria——Dr Frederick W Lamb has been appointed to succeed Dr William Muehlberg on the staff of the Cincinnati City Hospital——Dr Charles L Harmer has resigned from the staff of the Massillon State Hospital, Drs J D O'Brien and D E Harris have been promoted from internes to assistant physicians, and Dr H F Vaughan has been promoted from druggist to assistant physician

Colleges Open—Dr Starling Loving, Columbus, opened the fifty eighth session of the Starling Medical College with a clinical lecture, September 14 Additions to the teaching force are Dr Sissons in the department of anatomy, Dr Clement Jones in biology and embryology, and Dr Sterling B Taylor, demonstrator of anatomy, vice Dr Louis Kahn——Toledo Medical College opened for its twenty fourth annual session, and its first session as a department of the Toledo University, September 22

PENNSYLVANIA.

Personal.—Dr John P McCord, Pittsburg, has been elected surgeon general of the Union Veteran Legion——Dr and Mrs James M Anders, Philadelphia, have returned from an extended visit in Europe

Smallpox in Pottstown—Smallpox continues and is apparently on the increase in Pottstown, and general vaccination is to be carried out An order has been issued preventing all pupils who have not been successfully vaccinated from entering the public schools

Diphtheria in Chester Schools—Since the opening of the public schools in Chester several cases of diphtheria have been discovered among the pupils The disease is scattered throughout the city, and the authorities claim that the epidemic is due to weather conditions, and not to any sanitary defects in the buildings

Asks Increased Powers.—The State Board of Medical Examiners has prepared a bill which will be introduced at the next session of its legislature, giving the board the power to cancel any license issued by it whenever it appears that the holder is not a fit person to be so licensed because of lack of education or unsatisfactory professional and moral character

New Pittsburg Hospital.—St Joseph's Hospital, Pittsburg, was opened for public inspection September 20 The first floor of the building is devoted to the administrative department, dining room, kitchen, etc, on the second floor are the medical and surgical wards and the operating room, and the third floor is used for dormitories for the nurses and resident hospital staff The staff consists of Drs Otto Gaub, John P Saling, M L Schoenfeld, Benjamin B Wood, Alexander R Hampsey, Thomas P Cochran, Charles H. Hertzog, Christopher C Hersman and G Arthur Dillinger

Philadelphia

Public Baths—The 16 public bath houses maintained by the municipality have been closed for the season During the season 4 725,142 persons, including 3,525,736 boys, 1,072 941 men, 98,952 girls, and 27,513 women made use of the baths, an increase of 734,525 over the bathers of last year

Smallpox Hospital Closed—The smallpox building of the municipal hospital has been closed and thoroughly fumigated This is the first time in five years that the building is without an occupant The freedom of the city from the disease is attributed to universal vaccination, and this is to be continued by house to house visitations during the entire winter

Brunton and Liebreich in Philadelphia—Sir Lauder Brunton, F.R.S London, formerly lecturer on therapeutics in St Bartholomew's Hospital, London, and Prof Dr Oscar Liebreich, professor of pharmacology in the University of Berlin, addressed the students of Jefferson Medical College Friday, September 30, and were entertained at dinner by Dr Hobart A Hare in the evening

Health Report.—The typhoid situation is much improved The number of new cases reported for the week was 97 This is a decrease of 37 over the preceding week In all 186 cases of contagious disease were reported, with 23 deaths, as com pared with 234 cases and 27 deaths for the previous seven days The general death rate remains low, and the deaths from all causes for the week aggregated 401, a decrease of 7 from those of last week and a decrease of 9 from those of the corresponding period *of last year*, 51 deaths resulted from tuberculosis

Medical Colleges Open—The medical department of the University of Pennsylvania opened for its 139th session September 30 The exercises were held in the new laboratory building, and Dr John H. Musser delivered the address ——Hon William Potter, president of the board of trustees, delivered the address at the exercises, which marked the opening of the 80th annual session of Jefferson Medical College, which were held in the new college building, September 26 ——The Medico Chirurgical College of Philadelphia held its 23d annual opening exercises September 28 Dr Judson Daland delivered the address of the evening ——The 55th session of the Woman's Medical College of Pennsylvania was opened September 21 Dr Clara Marshall the dean delivered the opening address

TENNESSEE

College Opens Later—Tennessee Medical College Knoxville, will open for the year, November 1 a month later than usual

Epidemic Disease.—There are three cases of smallpox in Grundy County at Coalmont All necessary precautions have been taken ——Sumner County is reported to have an epidemic of scarlet fever Three cases have been found at Portland 2 at Fountain Head and 9 at Grabeall, with one death Schools have been closed.

Personal.—Dr William A Duncan Nashville has passed the examination for admission to the medical department of the Army and is ordered to report for duty in Washington, October 1 ———Dr Z D Massey, Sevierville is unopposed as candidate for state senator from the fourth district ——Dr John P Bates, St Bethlehem has been appointed a member of the sanitary staff of the Isthmian Canal Commission, and left for his post of duty, September 20

TEXAS

Personal—Dr Joseph S Wooten, Austin, is seriously ill with typhoid fever ——Dr Thomas M Colley, a retired physician of Palestine was run over by a buggy, September 15, and seriously injured

Yellow Fever Kept Out.—The U S Public Health and Marine Hospital Service and the state health authorities of Texas have succeeded in preventing the introduction of yellow fever across the American border from Mexico Last year the disease managed to get into some of the American towns on this side of the border New Orleans quarantined against a number of Texas points, and the state health boards of a number of southern states took the matter up The work this year has been directed toward extermination of mosquitoes along the border and has been quite successful Mexicans and Americans have joined in doing all they could to prevent yellow fever getting a foothold in this country this year So far there has not been a single case in the country

WASHINGTON

Tacoma's Health—During August 54 deaths occurred, equivalent to an *annual death rate of 9 96* per 1,000 Three cases of consumption, 4 of smallpox, 3 of measles, 20 of typhoid fever and 2 of diphtheria, were reported during the month

Medical Building for Seattle—Local physicians and capitalists are to erect a ten story building, to cost $200,000, to be occupied exclusively by physicians, and to be known as the Medical Building The lower floor will be occupied by a prescription drug store and a medical supply house

School Children Inspected.—For the first time in the history of Everett, thorough inspection of school children was made, September 7, by physicians of the department of health Two suspicious cases were found, and the children sent home —— Medical inspection of Seattle school children began September 6

WISCONSIN

Healthy Milwaukee—During August 330 deaths were reported equivalent to an annual death rate of 11 95 per 1 000 Tuberculosis caused 30 deaths, organic heart disease, 29, violence, 17, and diarrheal diseases, 75

Physician Enjoined—Dr L W Zochert, Hingham, has won his suit against Dr J H Blekking, of that village, whose practice he recently bought out, with the condition that Dr Blekking would not practice medicine in neighboring towns The latter resumed practice, however, and Dr Zochert brought suit against him The judge granted an injunction against Dr Blekking

Milwaukee Colleges Open—Milwaukee Medical College opened for the first session of its second decade September 20 Dr William H Earles delivered the address of welcome, and Dr William G Doern, formerly of Fort Madison, Iowa, the newly elected professor of anatomy, the formal address of the evening ——The opening exercises of the Wisconsin College of Physicians and Surgeons were held September 20 Dr Arthur J Patek delivered the address to the matriculants

Health Teacher Fined—'Dr" Mak, claiming to hail from Colorado, but who also says he has been a 'health teacher" in Wisconsin for many years, was fined $50 and costs, or sixty days in jail, September 3, on the charge of practicing without a license in Ashland The sentence was suspended twenty four hours, to give him time to get out of town With a view, however, of protecting the citizens of Wisconsin, notices have been sent to cities throughout the state notifying the authorities to be cautious and to see to it that "Dr" Mak does not attempt to practice medicine in their vicinity

GENERAL

Mississippi Valley Medical Association—The thirtieth annual meeting of this society will be held at the Grand Hotel, Cincinnati, October 11 13

Hospital for Manila.—The Board of Health of Manila and the Secretary of the Interior have approved plans for a building to be used as a civil hospital, on the grounds on Calle Padre Faura, known as the exposition grounds

American Neurological Society—At its annual meeting at St Louis this society elected the following officers for the ensuing year President, Dr Z W Spiller, Philadelphia, vice presidents, Drs Philip Zenner, Cincinnati and William Lullard, Boston, secretary, Dr T M Hammond, New York City Philadelphia was selected as the meeting place for 1905

New Hot Springs—The United States government is preparing to spend $600,000 in improving the reservation and park at Sulphur Springs in the Chickasaw nation, I T, for the purpose of making a second Hot Springs similar to the famous Arkansaw resort It is to be maintained by the government in the same manner as is Hot Springs, Ark, but will be even more beautiful and picturesque. There are three groups of springs and abundant fresh water of good quality in sufficient volume for city water supply

Sanitary Conditions in Panama.—An interesting feature of the sanitary work of the canal zone consists of what is known as "mosquito engineering" Owing to the heavy and intermittent rains, anopheles abound. Breeding places have been found in the Ancon grounds at Colon, where the hospital is situated, and all the collections of water contain the larvæ. One of the worst localities in Culebra, where the actual work of excavation is going on and malaria is very prevalent among the laborers In order to prevent smallpox an ordinance regarding vaccination has been promulgated by the chief medical officer

Luncheon to World's Fair Visitors.—A luncheon was tendered the delegates of the biologic and medical sections of the International Congress of Arts and Science by the faculty and staff of teachers of the medical department of Washington University, Sept 21, 1904 Among an attendance of 100 the following eminent men participated Theobald Smith, Harvard University, Oskar Hertwig, Berlin, Yves Delage, member of the Institute of France, Wilhelm Waldeyer, Berlin, S J Meltzer, New York, Max Verworn of Göttingen, Pierre Janet, College de France, Paris, Morton Prince of Boston, William Osler of Johns Hopkins, William T Councilman of Harvard, William T Sedgwick, Massachusetts Institute of Technology, Ronald Ross, Liverpool, Ludvig Hektoen, Chicago University, Johannes Orth, Berlin, Sir Lauder Brunton, London, Frederick C Shattuck, Harvard, T Clifford Allbutt, Cambridge, William S Thayer, Johns Hopkins, L F Barker, Chicago, Shibasaburo Kitasato, University of Tokio, James J Putnam, Harvard, Charles L. Dana, Cornell University, Edward Jackson, Denver, George M. Gould, Philadelphia, Sir Felix Semon, London, Theodor Escherich, Vienna, Abraham Jacobi, New York, John H Musser, Philadelphia, William B Northrup, New York, R. A Reeves, Toronto, William H Welch, Johns Hopkins

Cancel Charter of a Fake Medical College—On two or three occasions THE JOURNAL has referred to a diploma mill that has been in active operation in Guthrie, Oklahoma, under the title of "The Twentieth Century Physio Medical College" Last week a suit was filed in one of the district courts of Oklahoma Territory by the attorney general of the territory against this college to have the charter canceled The petition for the revocation of the charter states that the concern was organized by H Warner Newby, C A Newby and M E Newby, and that it was for the purpose of carrying on an educational institution for the conferring of degrees, etc., "that instead of conducting the institution as a medical college it has been fraudulently used for illegal means of issuing diplomas, and that instead of issuing these as a result of a legitimate course of study, the diplomas were sold at wholesale" The institution was at one time sending out circulars, not only from Guthrie, but from a little town in Pennsylvania, and through the efforts of THE JOURNAL the postal department undertook to get a case against it, but those connected with the Pennsylvania end of the concern discovered that they were being investigated and stopped. Beside the Twentieth Century Physio Medical College, the same individuals were conducting the "Twentieth Century Health Association," which, according to their circular, was incorporated under the laws of Oklahoma Of this concern Calvin D Gully was president, and H Warren Newby secretary Ostensibly, this association was organized "to advance the cause of liberal medicine and the mutual protection of members of our association, and to form a stronger combination, where all can be benefited and have legal protection wherever they wish to go" The real object, however, appears farther down in the circular, where it is stated that the shares are $10 00 each, and each member of the association holding one share "will receive a large, handsome certificate, with a beautiful seal and ribbons, which will be a fine ornament to your office We wish the co operation not only of the physicians of the association, but every healer and every good citizen in the country Every one who sends $10 00 will receive one of these handsome certificates, 19x28 inches, as fine as any diploma you ever saw" To show the connection of the Twentieth Century Health Association and the concern against which legal steps are now being taken, a footnote in the circular says "Graduates of the Twentieth Century Physio Medical College, Guthrie, O T, can practice anywhere in the United States"

CANADA

Hamilton Supports the National Sanitarium—The Hamilton Branch of the National Sanitarium Association has recently contributed $1,000 toward the maintenance of patients in the Hamilton and Wentworth County Pavilion of the Muskoka Free Hospital for Consumptives This makes $4,000 received from Hamilton altogether for the support of their consumptive poor

Personal.—Sir Lauder Brunton was recently the guest of Professor McPhedran of the University of Toronto——Prof William Osler has been visiting in Montreal and Toronto——Dr Charles O'Reilly, medical superintendent of the Toronto General Hospital, has been elected vice president of the Association of Hospital Superintendents——Dr Brefney O'Reilly, Toronto, has been appointed surgeon on the C P R steamship *Tartar*, and has gone to Vancouver to assume his new duties——Dr H A Bruce, one of Toronto's leading surgeons, and who was recently operated on for appendicitis, is rapidly recovering

To Quarantine All Inebriates.—A meeting of those interested in the treatment of inebriates was held at Government House, Toronto, September 19, Premier G W Ross being in the chair Dr T D Crothers, Hartford, Conn, delivered the principal address, outlining a system for the care and treatment of inebriates Dr A M Roseburgh, Toronto, told what had been done in Toronto and the province of Ontario Professor McPhedran of the University of Toronto introduced a resolution to the effect that the time was now ripe for the formation of a society for the reform of inebriates This was carried and another meeting will be held soon to organize

Vancouver Hospital.—The report of the house surgeon of the Vancouver General Hospital for August shows that there were 58 in residence at the beginning of the month, and that 37 were admitted during the month Eighty one were discharged as cured, three died and sixty one remained at the end of the month The number of hospital days was 1,810 The special committee appointed regarding the medical staff reported as follows That the active staff be composed of 12 Drs Johnston, S J Tunstall, W D Brydone Jack, Weld, Langis, Poole, Drier, Monro, Boyle, R E McKechnie and Mills, with one to be appointed by the directors The following will compose the consulting staff Drs D H Wilson, Lefevre, McGuigan, Carroll and Underhill

Montreal General Hospital—The regular quarterly meeting of the Montreal General Hospital was held last week, when it was decided to alter the constitution so as to leave the medical board free to engage the officers of the resident medical staff from outside of the British dominions The clause now reads "No person shall be eligible as resident medical officer unless he is a graduate or licentiate in medicine of some university or college approved by the medical board" The following is the medical staff for the ensuing year Drs J L. Robinson, J C Fysche, W G Bicker, J A Nutter, L L Reford, W W Kerr, H G Wood, R B Forbes, A C Rankin and W E Ainley Dr J Alex Hutchison read the medical report for the past quarter which showed that 781 patients were treated to a conclusion There were 67 deaths, of which 26 occurred within three days of admission, making the mortality for ordinary hospital cases 5 5 per cent In the out door departments there were 9,072 consultations

FOREIGN

Sanitation in Mexico—President Diaz, in his annual message, reports the gratifying result of the sanitary campaign against yellow fever, and states that there has been no recurrence of the disease in epidemic form during this year

Spanish Red Cross Society—It is reported that the Spanish Red Cross Society voted to send 25,000 pesetas ($4,750) to aid the Japanese branch of the society It was proposed to send an equal amount to the Russian branch, but the proposal was rejected almost unanimously

Gen Kuropatkin's Gifts to Medicine.—The Military Medical Academy at St Petersburg has recently installed a portrait of its honorary member, General Adjutant Kuropatkin, in the main hall as a token of gratitude for his gifts The academy owes to him the remodeling and enlargement of several of its scientific departments and institutes

Bubonic Plague—A recent issue of the public health report of the Marine Hospital Service records cases of plague in widely separated localities The disease is present in several towns in Cape Colony and in other parts of Africa An outbreak of plague is reported from Brazil, in Rio de Janeiro ten new cases were reported in one week

Public Disinfection in Spain—A decree has just been issued in Spain ordering undertakers to disinfect the room after a death The *Siglo Medico* comments on the importance of the decree, especially for the homes of the poor, as the neighbors flock to the funeral, unmindful of danger even in cases of diphtheria, smallpox, tuberculosis, measles or other disease The authorities order that the disinfection shall be undertaken as soon as the undertakers are notified Our exchange, however, expresses the fear that the decree will be practically a dead letter, like so many of its predecessors

The German Training School for the Disinfection Service—The authorities in Prussia organized last year a number of training schools to fit persons for the public disinfection service Fourteen have been in operation, each giving a course of at least nine days altogether, and restricting the students at each course to ten Sixty courses have been given in all, with a total attendance of 601, 585 have passed all the tests and been duly qualified as "graduate disinfectors" The authorities have been so much pleased with the results accomplished that they are urging physicians to call the attention of suitable persons to these courses and advocate their attendance It is hoped that every district will have one or more of these expert disinfectors residing in it Special courses for nurses are also planned It is found that the disinfection service has gained immensely in efficiency in the hands of the graduates of these schools

To Divert the Young from the Medical Profession.—A circular has been sent by the organized medical chambers of Germany to the high schools, warning the graduates from entering on the study of medicine A number of these circulars were thus placed in the hands of the principals of 482 academic and

131 technical high schools, with the request that they would distribute them among their pupils The overcrowded condition of the profession is set forth and the pecuniary stress of the majority of the members, due to overcrowding, to contract practice and to the lack of legislation against the irregular practice of medicine The circular further cites statistics to show that 31 per cent of all the physicians in the Brandenburg Berlin district have an income of less than $750 In Berlin alone more than $5,000 had to be distributed to needy physicians during 1902, and in Bavaria 23 physicians in 1902 and 20 in 1903 had to be assisted In 1901, 138 physicians, 1,387 physicians' widows and 309 orphans were partially supported, and many others who needed assistance refrained from applying for relief The Berlin Medical Chamber often has occasion to help needy physicians or their widows to obtain positions in libraries or the like. On the other hand are to be considered the scant consideration accorded to the physician in these days and the hardships of a doctor's life "In addition to all this,' the circular concludes, "long years must pass after entering the university before the candidate for the medical profession can even begin to support himself by his practice"

Correspondence.

The Danger of Giving Certificates of Physical Disability to Beggars

Muscatine, Iowa, Sept 26, 1904

To the Editor —A few days ago a man came into my office and asked that I give him a certificate as to the condition of his heart He told me that he was on his way west to his family and that he was out of money, in a serious condition and was soliciting aid I examined him and diagnosed aneurism of ascending aorta with mitral insufficiency He stated that his trouble dated from last February and that he had been before the medical class at Ann Arbor, Mich and some other college, and had been told that he could not live long and had certificates from a number of physicians in good standing His case was so interesting from a medical standpoint, per auscultation, that I called in a nearby colleague, Dr A J Oliver, who examined him and concurred in my diagnosis, and we signed a certificate to the effect that he had a serious circulatory lesion, but we made no recommendation for charitable assistance He thanked us for the certificate and went out on the street, where he had a phaeton with a couple of pillows to prop him up and a boy to drive him about He would stop in front of a business house or office, call out the proprietor, tell him his hard luck story, show his certificate and solicit cash In this manner he worked the business district with excellent success until he was found to have forged a prominent business man's name to his subscription list for the influence it would have, and the police ordered him out of town We, of course, were questioned as to our motive in giving him a certificate While the man is physically a wreck his charitable motive appears questionable He certainly would not have to solicit in many places as successfully as here until he could travel across the continent in a parlor car Is he a charitable fraud? He gave his name as Z V Good and is a man about 40 years of age with a conspicuous scar over left orbital bone

T F Beveridge M D

[Note —Newspaper accounts show that this man operated the same scheme in Cedar Rapids —Ed]

Life Insurance Examinations.

Des Moines, Iowa Sept 20 1904

To the Editor —In the issue of September 3 Dr O A Rea mildly rebukes the Des Moines physicians for adopting a fee bill providing for minor charges of $2 for day visits while a minimum of only $2 is charged for life insurance examinations

Permit me to say that I believe his conclusions regarding low fees for life insurance examinations are well founded A typographical error however, made the item read $2 to $5 for day visits, instead of $2 to $3, as provided

The doctor's remarks might lead one to believe that the fees for life insurance examinations have been reduced, which is far from being true On the other hand, the minimum fee has been advanced 100 per cent A number of fraternal societies doing business here, and in other states, have a fixed rate of $1 per applicant, which includes, beside a general examination a chemical urinalysis Some certificates of health have been issued by physicians to certain societies for even less than $1, which all must admit is deplorable in the extreme

While I would not compare the services of the physician to his patient in a matter which concerns the health, or even the life of the latter, to the business proposition relating to a life insurance policy, as does Dr Rea it is, nevertheless, true, as the doctor remarks, 'beneath the dignity of the profession of medicine" to accept the paltry fees proffered by certain societies and corporations for medical examinations on which the very life of the institutions depend

The Medical Profession and the French Chamber of Deputies.

Paris, Aug 28, 1904

My previous letter from here related chiefly to the medical profession as represented in the Senate of France I have since had an opportunity to investigate some of the facts relative to similar representation in the Chamber of Deputies This is the popular branch of the French Congress, its members are elected by direct and universal suffrage, each deputy must live in the arrondissement from which he is elected and consequently, can not represent two constituencies at the same time, and each chamber, or legislature, as it is called in France, is elected for a period of four years The basis of representation is one for each 100,000 inhabitants, with an additional representative for each additional 100,000 or fraction thereof In such instances an arrondissement is divided into circumscriptions like that of Dordogne, for instance which sends six deputies The body thus chosen consists of 561 members, of which, in the present legislature, fifty one are representatives of the medical profession

It is very interesting indeed to study this body of professional men, particularly when one object of that study is to compare the French with the American profession in their relation to the public life of the respective countries The first fact, by no means a surprising one, that impresses the student of political affairs in France is the marked evidence of individualism that is displayed in the multiplicity of parties These exist in such number and with such minor variations of title that, in many instances, their differences can be but little else than doctrinaire, if not metaphysical No one but a student, native to the soil and an active participant, could split terms with sufficient precision to clear up the mélange of definitions Nor is it necessary for our purpose We can see how the medical men are moving by recounting the titles they have given themselves as candidates before their respective electorates Thus, of the one more than a half hundred medical deputies, twenty one inscribe themselves as "Republicain Radical"—which, despite the contradiction of terms, is really the conservative wing of the republican movement, thirteen are "Radical Socialiste," which, I am advised, is the really radical party, standing as it does for everything that is embraced in the socialistic program After this general classification we get into a bewildering maze, in which we find four of our professional colleagues known as "Republicain Progressistes", a similar number simply as "Republicain", two as "Republicain Liberal"; and one each as "Republicain Collectivist," "Radical," "Radical Democratique,' "Socialiste Revisioniste," "Socialist," "Conservateur," and one as "Socialiste Blanquiste," whatever in the world that may mean No name of a physician occurs under such classifications as "Royaliste," 'Droit," "Droite Plebiscitaire," "Rallie," "Republican Catholique," or "Plebiscitaire Antisémite," groups which, in the aggregate, make up the clerical party as opposed to the government in the present controversy with the Vatican, and which stands, in one form or another, for everything in the *status quo ante* of 1870

If this extraordinary manifestation of individualistic activity were restricted to the medical members the prospect for the a member of the Ohio State Medical Association and the Academy of Medicine of Cincinnati, one of the most prominent physicians of Cincinnati, died at the Good Samaritan Hospital in that city, September 18, three days after an operation for appendicitis, aged 51 The faculty of the college, at a special meeting, September 20, passed resolutions eulogistic of their departed colleague and beloved friend

Charles E Pease, M D Department of Medicine of the University of Pennsylvania, Philadelphia, 1882, of Middletown, Pa, surgeon for the Pennsylvania System and the American Tube and Iron Company, died at the German Hospital, Philadelphia, September 12, from catarrh of the stomach, after an illness of several months and an operation for appendicitis, aged 47

John A Wegg, M D Western Reserve University Medical Department, Cleveland Ohio, 1865, a member of the American Medical Association, formerly a leading physician of Sandusky County, Ohio, residing at Rollersville, but who had lived in Cobreville, San Jago de la Vega, Jamaica, British West Indies, died recently at his home in Jamaica

Francis P Phelps, M D University of Maryland School of Medicine, 1853, surgeon of First Eastern Shore Volunteers from 1861 to 1863 a member of the House of Delegates of Maryland from 1893 to 1895, and a justice of the peace since 1900 died suddenly from acute gastritis at his home in Cambridge, Md, September 17, aged 74

Henry Ridgeley, M D Medical Department of the University of Pennsylvania, Philadelphia, 1839, and president of the Farmer's Bank of the state of Delaware, died at his home in Dover Del, September 17 aged 87 His death occurred suddenly and indirectly was due to hiccough, which began several days before

George P P David, M D Kentucky School of Medicine, Louisville 1891, for five years director of a large hospital in San Pedro Sula Spanish Honduras, died at his home in New Orleans, September 18, suddenly from heart disease, aged 45

Jacob Chambers, M D University of Buffalo, 1875, one of the managers, and surgeon of the City of Kingston Hospital family physician to Judge Alton Parker, died at his home in Kingston, N Y, September 16, aged 52

George Jacob Hirth, M D University of Michigan Department of Medicine and Surgery, 1891, of Milwaukee, died at a sanitarium in Wauwatosa, Wis, September 14, after an illness of a year, from paralysis, aged 38

Ellery G Fuller, M D Starling Medical College, Columbus, Ohio, 1888, died from Bright's disease, September 5, at his home in Sterling Center, N Y, after an illness of two weeks aged 46

Charles Conrad, M D Tulane University of Louisiana, New Orleans, 1897, committed suicide by shooting himself through the heart at his home in Cleveland Ohio, September 19, aged 35

James H Benton, M D Department of Medicine of the University of Pennsylvania, Philadelphia, 1876, of Newbern, N C died at Black Mountain, N C, September 14, aged 61

William L Whitted, M D Miami Medical College, Cincinnati, 1878, of Bloomington, Ind, died at Oceanside, Cal, where he had gone a year ago for his health, September 8

H Von Koehring, M D Friedrich Wilhelm University, Berlin, Germany, 1865, died at his home in San Antonio, Texas, September 14, from cerebral hemorrhage, aged 58

Andrew D Finucane, M D Bellevue Hospital Medical College New York City, 1884 of Chicago, died at the Illinois Northern Hospital for the Insane, Elgin, August 16

Frederick Dorsey Mitchell, M D University of Maryland School of Medicine Baltimore, 1846, died at his home near Hereford, Md, September 15, aged 80

Victor Rounds, M D Rush Medical College, Chicago, 1882 died recently at his home in Brainerd, Minn, and was buried at Verndale, Minn, September 20

Allen M Pierce, M D Rush Medical College, Chicago, 1861, an Army surgeon during the Civil War, died at his home in Wyoming, Ill, June 10

William N Ash, M D Toledo (Ohio) Medical College, 1883, died suddenly at his home in Mount Eaton Ohio, September 14, aged 45

G C Dortch, M D, of Clarksville, Tenn, died at the home of his daughter in South Ryegate, Vt, September 10, from heart disease

William H Wheeler, M D Indiana, 1897, died at his home near Hartford City, Ind, September 14, after a short illness, aged 80

Willard F Parsons, M D, died at the Spencer Hospital, Meadville, Pa, September 4, from an overdose of chloral, aged 49

Henry F Campbell, M D, of Melrose, Mass, died suddenly in Boston, from heart disease, September 14, aged 65

S A Meecham, M D, died recently at his home in Norden, Neb, from malignant disease of the head, aged 87

Charles Galloway, M D Rush Medical College, Chicago, 1892, died at his home in Libertyville, Ill, September 15

Julian Fajans, M D Jefferson Medical College, Philadelphia, 1886, died at his home in Philadelphia, August 26

Samuel S Strayer, M D Chicago Medical College, 1872, died at his home in Naperville, Ill, August 18

William M Henry, M D University of Louisville, 1885, died recently at his home in Onton, Ky, aged 66

Frank M Sisson, M D New York, 1881, died in Rochester, N Y, August 23, aged 49

D M Reagan, M D, died at his home in Buda, Texas, from cancer, August 14, aged 72

George Clough, M D, died at his home in Kansas City, Mo, August 23, aged 83

Deaths Abroad

Niels R Finsen, M D, pioneer in scientific phototherapy, died, September 24, in Copenhagen, aged 43 He was a native of the Faroe Islands He began his work while a student in the Copenhagen University, from which he was graduated in 1890 Three years later he published an article on "The Influence of Light on the Skin," which aroused general attention because of his assertion that smallpox could be cured by the red light treatment This was but one application of the Finsen theory that light rays contained healing powers, and to develop the positive element of his theory he began experimenting with concentrated artificial light rays As a result of his experiments, he effected a cure for lupus vulgaris This cure directed great attention to the young investigator, and in 1896 the Municipal Hospital of Copenhagen allowed Professor Finsen several small buildings on its grounds in which to carry on his experiments The Danish government then became interested in the support of the institution, and this support enabled the institute to be removed to Rosenvaenget, a suburb of Copenhagen, where under the direction of Professor Finsen, with a staff of scientists of national repute, expert electricians, and trained nurses, many cures of cases previously deemed incurable were made In December, 1903, Professor Finsen was awarded the Nobel prize For several years he had suffered from dropsy resulting from heart disease, but so intense was his devotion to his work that he hardly spared time from his studies for sleeping and eating much less to recuperate his health His death is attributable to an aggravation of the diseases from which he had suffered during his entire adult life by reason of his persistent overwork

H Kobner, M D, one of the founders of German dermatology and one of its most prominent representatives, died at Berlin, September 3, aged 66, just a few days before the dermatologists of the world were to gather at Berlin for the fifth international congress of dermatology Köbner founded at Breslau in 1861 the first clinic for skin diseases and syphilis in Germany, and later became director of the clinic established by the university but was soon compelled to resign on account of his health He settled in Berlin in 1877, where his dermatologic policlinic and postgraduate courses were very popular Among the subjects especially connected with his name are sycosis, mycosis tonsurans, leprosy, drug exanthemata, etc, his works on these and allied subjects having been numerous and important

State Boards of Registration.

COMING EXAMINATION

Board of Medical Examiners of the State of California San Francisco October 25 Secretary Charles L Tisdale M D Alameda

New Rules in Kentucky—The State Board of Health of Kentucky, in putting into effect the new law requiring all applicants for license to pass an examination, has adopted rules and procedures which we reproduce from a circular just issued by the board

REQUIREMENTS FOR MEDICAL COLLEGES AND STUDENTS

On and after July 1 1905 every medical college shall comply with the following requirements as a condition of being recognized as reputable by the State Board of *Health of* Kentucky

1 It shall uniformly exact the requirements for matriculation set forth in requirements for admission to medical colleges, adopted by this board

2 It shall literally *observe* its own published requirements for *admission*, tuition time of attendance at the annual sessions and graduation which must be definitely expressed

3 It shall have adequate equipment and an active and competent faculty for teaching the science and art of medicine embracing the following departments viz Anatomy, physiology, chemistry pathology histology bacteriology, surgery obstetrics gynecology ophthalmology otology hygiene and state medicine medical jurisprudence, physical diagnosis and therapeutics and practice in accordance with the system to which the college belongs

4 It shall have clinical and hospital facilities based on a minimum municipal population at its place of location of not less than 50 000, provided that this requirement shall not apply to institutions under state control which by virtue of such control receive patients gratuitously from all parts of such state

5 It shall require actual attendance on 80 per cent of each of four courses of instruction of not less than thirty continuous weeks excluding holidays, in four separate years and shall not hold more than one graduating course in any one year (It should be noted that no *provision* is made for giving advanced standing for A B B S or other degrees)

6 It shall not accept notes in payment of fees or offer or accept scholarships or any reduction in fees or any form of rebates except as provided for or required under state laws or under the laws of endowed universities and no student shall be given credit *for attendance or advanced* or graduated, until all fees have been paid

7 Colleges may honor official credentials issued by medical colleges of equal requirements as to students who have complied with the Requirements for Admissions to Medical Colleges. except in the branches of study embraced in the last year of their own *curriculum*

REQUIREMENTS FOR ADMISSION TO MEDICAL COLLEGES

All colleges shall require every medical student applying for matriculation on and after July 1 1905 to present to it A Medical Student s Certificate issued to him by a certified examiner of the *state board of* health or *state board of* medical examiners of the state in which such college is located, approved by such board and a certificate of good moral character

The examiner shall require as a basis for his certificate

(a) A degree of A B B S or equivalent from an approved university college or academy of arts, science or philosophy

(b) A *diploma or certificate of graduation from an approved* high school or normal school

(c) A state teacher s permanent or life certificate

(d) A medical student s certificate from any state board of health or examiners demanding equal requirements

Or an examination in writing in the following branches

(a) *English, submitting a composition* in his own *handwriting* on some subject of general interest embracing not less than two hundred words which shall be considered with reference to penmanship spelling pronunciation, thought and construction

(b) United States history

(c) Arithmetic. vulgar and decimal fractions percentage and *compound numbers*

(d) Algebra through equations

(e) Latin through first year of ordinary course

(f) Physics the elements of mechanics hydrostatics hydraulics heat optics and acoustics

GRANTING OF CONDITIONS

Applicants failing to obtain a general average of 75 per cent in the entrance examination and failing below 55 per cent in but two branches may be conditioned by the official examiner on a different form of certificate. The examiner shall make a separate list of such conditioned applicants in duplicate one copy of which shall be sent to the state board of health or examiners and the other retained in his office

REMOVAL OF CONDITIONS

Such conditions must be removed by the presentation of a certificate from the examiner that such applicant has passed a satisfactory examination in the branches in which he was formerly found deficient before he can receive *credit for the first* or be permitted to enter on his second year of study and the examiner shall furnish a list of such applicants to the state board of the jurisdiction

FEE.

Two *dollars is hereby fixed* as the fee to be collected by the examiner for each certificate in Kentucky *Those examined in* special subjects to remove conditions will not be required to pay again but those *failing and taking a* second examination will pay another fee

Kentucky Examination Announcement.—The first semiannual examination by *the State Board of Health of Kentucky*, under the new medical law which became *operative* June 13, 1904 will be held at the School Board Building, corner Center and Walnut streets, Louisville, beginning at 10 a m , on Monday Oct 3 1904 and continuing for three days All applications should be sent to the board at Bowling Green at least five days prior to the date fixed for the examinations, and applicants should be present by 9 a m of the first day No one can be examined who is *not* reputable in the school or system of practice to which he *professes to belong*, and who does not hold a diploma issued to him by a college located within the United States recognized as being reputable by this board Each applicant must present to the secretary at the examination, a recent photograph of himself, the reverse side of which shall contain his signature, written in the presence of the secretary, and he shall make oath before such officer that it is his true picture and signature, and that he is the legal holder of the diploma under which the application is made The filing of an application, or taking an examination, does not authorize the applicant to practice, and no one can legally engage in practice until he has obtained his certificate and registered in the county of his residence Non residents and holders of foreign diplomas are not eligible for examination The fee of ten dollars should be sent to the secretary, Dr J N McCormack, Bowling Green, Ky , with the application

The Public Service.

Army Changes.

Memorandum of changes of station and duties of medical officers U S Army week ending Sept 24, 1904

Devereux J R, asst surgeon left Fort Meade S D, with Sixth Cavalry on road march

Smart, Charles *asst surgeon general* Smart, Robert and Metcalfe R F asst surgeons arrived at San Francisco on the *Sherman* from Manila P I

Church James R *asst. surgeon relieved from duty* at Fort Brown, Texas on expiration of sick leave and ordered to Fort Robinson, Neb

Stark Alexander N asst surgeon reports *on* three months sick leave from date

Greenleaf Henry S reports on ten days leave from date on completion of duty at maneuvers

Appel D M, deputy surgeon general leave of absence extended to include Oct 30 1904

McAndrew P H asst surgeon left Jefferson Barracks, Mo with *recruits to* San Francisco

Kean Jefferson R and Rafferty Ogden surgeons detailed to represent Medical Department of the Army at the Thirteenth Annual Meeting of the Association of Military Surgeons of the United States to be held at St Louis Oct 10 15 1904

Stephenson Wm surgeon granted thirty days leave, permission to apply for twenty days extension

Smart Charles asst surgeon general ordered to proceed from San Francisco to Army and Navy General Hospital Hot Springs Ark for treatment

Williamson, L I asst surgeon *relieved from further duty* as medical director Louisiana Purchase Exposition St Louis and in addition to his duties as attending surgeon headquarters Northern Division, he will perform the duties of examiner of recruits, St. Louis.

Buck Carroll D asst surgeon in addition to his present duties *will perform temporarily* the duties of medical director, Philippine Government Board Louisiana Purchase Exposition, St. Louis

Owen Wm O surgeon, discharged from observation and treatment at U S Army General Hospital Presidio of San Francisco

Owen Wm O surgeon relieved from duty in Philippines and to proceed from San Francisco to Fort Logan Colo for duty

Steer, Samuel I asst surgeon granted thirty days leave of absence.

Lyster Wm J L asst. surgeon, leave of absence extended thirty days

Greenleaf, H S asst surgeon granted thirty days' leave of absence with permission to apply for thirty days extension

Brooks John D contract surgeon ordered to temporary duty at Fort Washakie Wyo not later than September 13

McMillan Clemens W contract surgeon ordered from Fort Niagara, N Y to temporary duty at Fort Hamilton N Y

Boak S Davis, Lauderdale Clarence E. Mason, George L and Wing Franklin F contract dental surgeons arrived at San Francisco September 16 on the transport *Sherman* They have completed three years duty in the Philippines and have been assigned to stations as follows Dr Boak to Fort Hancock N J Dr Lauderdale to Fort Sam Houston, Texas Dr Mason to Fort McPherson Ga and Dr Wing to Fort Riley Kan

Navy Changes.

Changes in the medical corps, U S Navy for the week ending Sept 24, 1904

Curl H C P A surgeon detached from the *Boston* and ordered to duty in connection with the Isthmian Canal Commission

McDonell W N A A surgeon detached from the Naval Recruiting Station Baltimore Md and ordered home to wait orders

Rodman S S P A. surgeon, detached from the *Pensacola* and ordered to the *Boston*

Wilson H. D P A. surgeon ordered to additional duty on the *Southery* September 28

The following named asst. surgeons are detached from the stations indicated and ordered to the Naval Museum of Hygiene and Medical School Washington, D C September 30 R G Heiner, *Southery* R B Chapman, Navy Yard Washington D C R E Stoops, Naval Hospital Norfolk, Va. F E Porter Naval Hospital. Norfolk, Va. H F Hull Naval Hospital Newport, R. I W D Owens Naval Hospital Newport, R I J L. Belknap Naval Hospital N Y D C Cather Naval Hospital New York N T McLean Naval Hospital New York G L Wickes, Naval Hospital Philadelphia W J Zalesky Naval Hospital Philadelphia O J Mink, Naval Hospital, Philadelphia H A May U S R S *Franklin* C T Grayson Naval Hospital Washington D C W A. Angwin, Naval Hospital Mare Island Cal W G Farwell, Recruiting duty Portland and Bangor Maine

Braisted, W C surgeon detached from the *Pensacola* and ordered to the *Ohio*

McCullough, F E surgeon ordered to the *Pensacola* and to duty at the Naval Training Station San Francisco

Kennedy, R M, surgeon, detached from the *Dixie* and ordered to the *Missouri*

Lovering, P A surgeon, ordered to the Naval Museum of Hygiene and Medical School, Washington D C, October 3

Ferebee N McP medical director, sick leave extended three months from September 20

Marine-Hospital Service

List of changes of station and duties of commissioned and non commissioned officers of the Public Health and Marine Hospital Service for the seven days ended Sept 21, 1904

Gassaway, J M, surgeon detailed to represent the Service at the meeting of the Association of Military Surgeons at St Louis October 10-15

Carmichael D A surgeon, granted leave of absence for one month from October 18

White J H, surgeon granted leave of absence for six days from September 19

McIntosh, W P surgeon, to proceed to Stonington, Maine for special temporary duty

Woodward, R M, surgeon, Department letter of May 13 1904 granting leave of absence for three months amended to read two months and twenty six days from June 14

Stoner J B, surgeon, to proceed to Cape Charles Quarantine Station and assume temporary charge during the absence of Asst. Surgeon J S Boggess, granted leave of absence for eight days from September 26

Wertenbaker, C P surgeon on being relieved from duty at New Orleans La by P A Surgeon A C Smith to proceed to the Immigration Depot Ellis Island, N Y and report to Surgeon G W Stoner for duty

Smith A C, P A surgeon on being relieved from duty at New York (Stapleton) by P A Surgeon J A Nydegger to proceed to New Orleans La, and assume command of the Service relieving Surgeon C P Wertenbaker

Nydegger, J A P A surgeon relieved from duty at the Immigration Depot, Ellis Island, N Y effective Oct 1 1904 and directed to proceed to New York (Stapleton and report to the medical officer in command for duty and assignment to quarters relieving P A Surgeon, A C Smith

Foster M H, P A surgeon granted extension of leave of absence on account of sickness for thirty days from September 18

McLaughlin, A J asst surgeon, granted leave of absence for twenty four days from October 3

Hamilton, H T, A A surgeon granted leave of absence for thirty days from October 1

Richardson S W, pharmacist relieved from special temporary duty in connection with the Louisiana Purchase Exposition at St Louis and from duty in the Hygienic Laboratory Washington D C and directed to proceed to Boston Mass and report to the medical officer in command for duty and assignment to quarters

LaGrange J V pharmacist Department letter of Aug 30 1904 granting leave of absence for twenty three days from September 15 revoked

Keen, W H, pharmacist, Bureau order of Aug 26, 1904, directing him to proceed to Boston revoked and directed to proceed to Chicago and report to the medical officer in command for duty and assignment to quarters

REINSTATEMENT

Bierman, C H, New York reinstated as pharmacist of the third class

BOARD CONVENED

Board convened to meet at Stapleton N Y Sept 10 1904 for the physical examination of an officer of the Revenue-Cutter Service Detail for the board P A Surgeon A C Smith chairman P A Surgeon C H Lavinder recorder

Health Reports.

The following cases of smallpox, yellow fever cholera and plague have been reported to the Surgeon General Public Health and Marine-Hospital Service, during the week ended Sept 23 1904

SMALLPOX—UNITED STATES

Illinois Chicago Sept 10 17, 14 cases 2 deaths
Louisiana New Orleans, Sept 10 17, 1 case (imported)
Massachusetts Sept. 10 17, Lawrence, 1 case, North Adams 9 cases
Michigan At 41 places Sept 3 10 present
Minnesota Morrison County Sept 6-13, 1 case
Missouri St Louis Sept 10 17, 11 cases
New York New York City, Sept 10 17 2 cases
Pennsylvania Philadelphia, Sept. 10 17, 1 case, 1 death
Rhode Island Providence, Sept 10 17, 1 case
Tennessee Sept 10 17 Memphis, 1 case Nashville 2 cases
Wisconsin Milwaukee Aug 27 Sept 17, 6 cases

SMALLPOX—FOREIGN

Belgium Antwerp, Aug 27 Sept 3, 1 case
Borneo Brunai Aug 8, epidemic
Brazil Pernambuco Aug 17 31 28 deaths
China Hongkong July 30 Aug 6 2 cases.
France Paris, Aug 27 Sept 3 20 cases, 1 death
Great Britain Bradford July 31 Aug 27 9 cases Aug 27 Sept 3, Bristol, 1 case London 2 cases, Manchester 2 cases Newcastle on Tyne 3 cases West Hartlepool 2 cases, Glasgow, Sept 2 9, 2 cases, 1 death Leeds, Sept. 3 10 1 case
India Bombay, Aug 16 23 1 death
Italy Palermo, Aug 27 Sept 3 9 cases 2 deaths
Russia Moscow Aug 16-23 7 cases 2 deaths Odessa Aug 23 Sept. 3 7 cases, St Petersburg Aug 20 27 2 cases 4 deaths
Turkey Beirut Aug 20 Sept 3, present Constantinople Aug 28 Sept 4, 6 deaths

YELLOW FEVER.

Mexico Coatzacoalcos Sept 3-10 7 cases 2 deaths Sept 4 10 Merida 1 case Tehuantepec 1 death Vera Cruz, Aug 27 Sept 10 16 cases
Panama Panama Sept 5 12 1 case 1 death

CHOLERA

Borneo Kudat, Aug 19, present
India Bombay Aug 16-23, 12 deaths
Turkey Bagdad vicinity, July 23-Aug 6 844 cases 1,023 deaths.

PLAGUE

China Hongkong July 31 Aug 6 13 cases, 12 deaths
Egypt Aug 13 20, 10 cases, 7 deaths
India Bombay, Aug 16 23, 70 deaths, Karachi Aug 14 21, 4 cases, 2 deaths
Japan Formosa July 23 Aug 6, 21 cases 27 deaths
Turkey Smyrna, Sept 8, present

(*Continued from page 907*)

Operative Treatment for Painful Menstruation in Young Virgins.

Dr William A B Sellman, Baltimore, pointed out the great necessity of giving relief to young unmarried women who suffered from painful menstruation The forms of dysmenorrhea that could be relieved by operative means were expatiated on at length These means should not be of a character to unsex the patient nor prevent her from bearing children or from fulfilling her marital relations The operation should not be one which will endanger life or interfere with the woman s general good health To illustrate the condition and to demonstrate the manner in which cases could be operated on without unsexing the individual and giving absolute relief from the suffering experienced, he related the following case on which he operated in the early part of June, 1904 Miss H, aged 24, a brilliant vocalist, with a register of three octaves, had been unable to use her voice with any satisfaction for a long period on account of the pain developed in the ovarian region when attacking the high notes June 7, 1904, under ether anesthesia, the endometrium was curetted and a quantity of congested tissue removed from the cavity of the uterus He then made an abdominal incision in the median line, and found both ovaries hyperemic and distended Upon the left side he opened three good sized cysts and on the right side two medium sized cysts He enucleated these with a sharp spoon curette and scraped the walls in order to destroy the membrane He closed the openings with catgut sutures and used the same material to close the opening in the abdominal wall The patient made an uninterrupted and rapid convalescence, and had not had the slightest amount of pain in the ovarian region, and no pain during two menstruations which she had passed through since the operation He thought very many gynecologic surgeons would have removed both ovaries under these conditions and the result would have been the unsexing of the patient and probably the loss of her voice, especially in the upper register He had heard her sing, and was certain that her voice had not been impaired Two physicians present during the operation expressed the opinion that no relief would follow the operation unless he removed the appendages Resection of the ovary was followed by such successful results that one was not justified in removing the organs unless the complications present gave no opportunity to perform the conservative opera tion Lastly, he spoke of that class of cases in which dysmenorrhea was due to a general systemic neuralgic condition In these cases one at times afforded great relief by the use of the various forms of electricity It was doubtful in many of the cases whether removal of the appendages would accomplish anything more than to bring about a premature menopause, and the patient would remain just as nervous as before operation

DISCUSSION

Dr. H. W Longyear, Detroit, Mich, stated that in operating, if one could save an ovary or part of an ovary, he should do so In the majority of cases, one could conserve tissues there with perfect safety and with the result of allowing the woman to menstruate as she would in a normal condition He would enter a protest against operating on cases of dysmenorrhea that were of short duration in young persons One should not suject any unmarried woman to an operation if it could be avoided The minor cases of pain of short duration did not need operative measures

Dr. Herman E Hayd, Buffalo, N Y, alluded to the importance of examination in these cases, and even after an examination was made one might find that the most distressing cases were the ones that practically had no evident pathology, which could be made out by such an examination If on examination one should find a retroverted uterus, a prolapsed ovary, a tender sensitive tube, then there was a rational basis on which to work, but simply because a woman had a small os it did not follow that she was going to be the subject of dysmenorrhea, because in all probability most of these cases were simply due to an impoverished condition of the whole system They were simply functional troubles, and had to be met accordingly If, however, there was an obstructive dysmenorrhea, and usually these cases were associated with an atrophic condition of the uterus, probably one could institute some operative measures, and the interference which had been most successful in his hands had been dilatation and the wearing of a stem pessary

Dr. William H. Humiston, Cleveland, Ohio, stated that dysmenorrhea was a common disturbance, and yet he had not been able to find a case that was not accompanied by an inflammatory condition of the mucosa He had seen cases of narrow, conical os, with the patients menstruating without the least sign of distress, but the moment there was an inflammatory condition of the mucosa added, that moment the patients began to have painful menstruation In cases of this kind he thoroughly dilated the uterine cavity, curetted, and had the patients wear an Etheridge pessary, closely watching them for several months, and if there was no accompanying disease of the appendages, the cure was decided and complete In these cases occasionally one would have a failure because of not recognizing an ovary which was smaller than normal, the cirrhotic ovary, which was hard to detect unless an examination was conducted under an anesthetic, and there was no relief afforded except by the removal of these shrivelled, corrugated, smaller than normal ovaries

Dr. D Tod Gilliam, Columbus Ohio, spoke of the undeveloped condition of the uterus as a cause of dysmenorrhea. A great many men had come to the conclusion that it was not a superficial condition, it was not produced by the condition of the mucosa, as a rule, nor the result of stenosis of the internal os or of many of the other orifices of exit, but was due to the undeveloped, unripe condition of the uterine tissues The uterine tissues were just like unripe fruit, and one of the functions of the uterus was to throw off this membrane at stated intervals, and in doing so there were certain physiologic processes that must work their way or be concerned therewith The time for the casting off of this membrane was at the menstrual period, a time when this membrane would easily come away, but which could not be removed at any other time without more or less violence. Vessels permeated this dense structure, these vessels were undeveloped, they were unable to accommodate the amount of blood sent there during the menstrual molimen, and this induced distress The membrane closely adhering to the uterine wall was not ready to be exfoliated hence it was a source of distress

Dr. John Young Brown, St Louis, Mo, said that his experience in dealing with cases of painful menstruation was that unless there was a palpable pathologic condition present, it was better to leave them alone In looking up the etiology of pelvic disease, he had found in a rather extensive operative experience that the majority of cases that came to operation were of gonorrheal or puerperal infection, and those cases that came as the result of infection following minor office gynecologic procedures He did not feel that a young woman who suffered from painful menstruation should be subjected indiscriminately to operative treatment or even to a gynecologic examination

Dr L H Dunning, Indianapolis, said that one ought not to approach any case of dysmenorrhea without studying the surroundings very carefully He should have a complete and thorough history of the case in order to be able to determine the character of the lesion which was present before undertaking the treatment of the case He had been surprised in studying the collected histories of some two thousand cases to find that in about 15 per cent of them there was dysmenorrhea at the beginning of menstruation This, he thought, would go to disprove one statement made by the essayist, that nearly all of the cases were due to inflammation, or that most of them were due to gonorrheal infection or some other kindred infection In the majority of cases in which dysmenorrhea began with menstruation, he thought one would find some errors in the development of the organ or errors in the development of the nervous system which would lead to painful menstruation Every case should be studied carefully on its merits Some would be found to be due to nervous conditions, others to hyperemia of the ovaries, and still others to venous congestion of the pelvic organs, including the uterus and ovaries Obviously, all of these were not cases demanding operative procedures

Dr. Sellman stated that the object of his paper was to prevent, if possible, this suffering to women which came on about thirteen times a year He thought that if any member of the Association had to undergo or endure the pain from which some of these patients suffered, even for only six times a year, he would seek some means of relief He did not use instruments in all cases, but only in those cases where a gristly condition existed

Pseudo-Membranous Monocystic Tubercular Peritonitis

Dr. H W Longyear, Detroit, said that pseudo membranous monocystic tubercular peritonitis was that form of tubercular peritonitis which was characterized by the formation of a thick, white, fibrinous, pseudo membrane on all of the tubercular peritoneum, covering the parietal peritoneum and cementing together and covering the intestinal coils in such a manner as to form a sac of greater or less capacity, according to the progress of the disease, which contained straw colored fluid, with occasionally jelly like masses and shreds floating therein He reported three cases of this affection, and stated that the treatment consisted of abdominal section, with evacuation of fluid and the thorough washing out of all shreds and gelatinous masses, with normal salt solution, thorough drainage by glass or rubber tubes, both abdominal and vaginal This was to be followed by after treatment consisting of frequent lavage, with a weak aqueous solution of iodin (tincture iodin, 1 dram, water, 1 pint), until the pseudo membrane was disintegrated and the purulent discharge that followed had ceased Internally, the rational treatment of tuberculosis, consisting of the use of creosote, cod liver oil, etc, a supporting diet, and suitable hygienic surroundings The prognosis was bad, although a few cases might recover, if not too far advanced, after months of constant drainage and careful nursing

DISCUSSION

Dr. Rufus B Hall, Cincinnati, said he differed from some writers in regard to the different varieties of tubercular peritonitis He was of the opinion that it was tubercular peritonitis in different stages of development In dealing with the operative treatment of tubercular peritonitis, ultimate success depended largely on the variety of the disease, the general condition of the patient, the previous history, the great prostration, etc Very many were in such a condition that they could not withstand much trauma of any kind The greatest relief was to be afforded to those cases in which there was an accumulation of cysts by letting out the fluid and draining He had time and again made section when the patients were in a desperate condition, put in a drain, and in six months or a year later the patients returned, when he removed one or two infected tubes, and cured them, whereas if he had done a prolonged operation at the outset, with the patients in a feeble condition, and unable to withstand trauma, they would not have rallied

Dr L H Dunning said there were two or three questions which ought to be settled in regard to the treatment of cases of encysted tuberculosis of the peritoneum First, as to whether one ought to remove the fallopian tubes in all instances He believed we should He believed that all cases of encysted dropsy, where the fluid accumulated in the pelvis, as described by Dr Longyear, were dependent on infection of the tube, and it ought to be removed or a fistula would persist indefinitely Another question was with reference to drainage He was in accord with both Dr Longyear and Dr Hall that these cases ought to be drained through the abdominal wall They need not be drained through the vagina if one could possibly drain them in the other direction Should one in these cases attempt to break up the adhesions? Dr Price had insisted on breaking up adhesions in all cases of tuberculosis of the intestines, but he believed that this pseudo membrane, which was an adventitious membrane thrown out, was protective, was conservative, on the part of nature, and that one ought not to attempt to separate adhesions Another point was whether we were justified in attempting to shorten convalescence in these cases by curettement In three of his own cases he had curetted sinuses and packed with gauze to the bottom of the cavity, and had had three recoveries In one instance there was a wide invasion in the abdominal wall and pelvis, and with a great deal of timidity he used the curette, but did it carefully, and packed This was followed by healing of the fistula within a short time

Dr Herman E Hayd Buffalo, N Y, said that usually those cases with simple effusion, or dropsy which was circumscribed, got well if opened and the opening immediately closed One did not need to disengage bowel nor disturb the adventitious membrane Simply the entrance of air was an important factor in the cure of these cases If there was pathology such as had been pointed out by the essayist, it was necessary to drain However he did not agree with Dr Hall that all cases of tubercular peritonitis should be drained, as his own experience did not bear that out

Dr J Henry Carstens, Detroit, thought that all that was necessary in ordinary simple, encysted cases of this condition was to wash them out and let them alone One should not try to break up adhesions, as serious complications might follow In tubercular peritonitis the patients should be let alone as much as possible, and Nature given a chance He said if he operated on a case of tubercular appendicitis and drained it, he would get trouble because along the track of his drainage tube there would be tubercular deposits and he would have a fistula there for a long time On the other hand, if he took out the appendix, closed up the opening with silkworm gut sutures *en masse,* tightly, he would have union without the formation of a fistula

Dr D Tod Gilliam did not believe in too much interference in cases of tubercular peritonitis, or in such cases as had been described He thought many of these patients would be better without operation if their cases were diagnosed accurately beforehand In some cases of encysted tuberculosis he did not care whether the contents were merely washed out or not, by one method or another one was likely to have bad results There were other forms of encysted tuberculosis, however, in which one did not have these bad results, and in such cases it was necessary to open up the cysts He did not believe in breaking up adhesions and separating viscera

Dr Longyear did not believe that a case of simple tubercular peritonitis, with a large cyst, and the abdomen full of dropsical fluid, needed to be drained, but agreed with Dr Hayd that all that was necessary to do was to open it, wash out the cavity, sew up the wound, and the patient would get well Many of them, however, would have a reformation of the fluid

Chronic Adhesive Peritoneal Sclerosis.

Dr N Stone Scott, Cleveland, Ohio, stated that among the rarer abnormal conditions found within the abdomen, was one peculiar, interesting, and possibly more frequent than had heretofore been suspected This condition was progressive, yet was characterized by an absence of active symptoms, including ascites In the early stages the peritoneum was rigid and contracted, later the connective tissue became excessively hypertrophied, with adhesions between the involved peritoneum and all viscera with which it came in contact As soon as these adhesions interfered with the functions of any organ, symptoms referable to such interference supervened. When the involvement prevented some important organ from performing its necessary functions, death ensued

In an illustrative case cited by him only a circumscribed portion of the peritoneum (the pelvis) was affected

The Relative Value of the Means and Methods Employed in Accouchement Force

Dr E Gustav Zinke, Cincinnati, Ohio, read a paper in which he drew the following conclusions 1 The graduated steel or vulcanite dilators and the ordinary branched or bladed dilators were mainly employed for the purpose of dilating the cervix or os preparatory to digital, manual and bag dilatation 2 The bag or hydrostatic dilators, of which the Champetier de Ribes balloon and its modifications were the most favored, should be employed only when time was not an important element in the case, when the cervix was thoroughly softened partly or entirely effaced, and an easy introduction of the balloon possible This was contraindicated in central placenta previa, and in eclampsia, mild or severe If, in these cases, it was determined to empty the uterus, deep cervical incisions, vaginal or abdominal hysterectomy, promised the best results for mother and child To prevent continuation of the cervical incision a suture might be placed in the upper angle of the wound 3 The manual dilatation of Harris and the bimanual (digital) dilatation of Bonnaire and Edgar A soft and partially obliterated cervix and dilatable os were absolute prerequisites for this variety of uterine dilatation It was to be preferred when time constituted an important element Under this method the life of the fetus was often lost and, unless great care was observed, sepsis, lacerations, hemorrhage, profound shock and sometimes even death of the mother might occur 4 Deep cervical incisions and Duhrssen's vaginal hysterotomy were destined to play a permanent and important rôle in the management of forced labors in the future Many of the cases now subjected to manual or balloon dilatation would be treated by cervical incisions It was the method in the presence of sepsis of the vagina, because the operation was short in duration and could be performed under a continuous flow of an antiseptic solution An intact cervix, whether hard elongated or not, was always an indication for cervical incision Vaginal hysterotomy was indicated principally when the cervix was the site of malignancy or extensive cicatrization If there were a palpable difference between passage and passenger, the conservative cesarean section should be the choice of operation 5 The indications for the conservative cesarean section had been well defined in previous papers and it was needless to repeat them Cervical incisions and Duhrssen's operation would however, take its place in many instances notably in cases of marked prematurity 6 The Bossi and similar metal dilators, if they were not entirely needless, were certainly very dangerous instruments From what had been said it was safe to predict that rapid and complete metal dilatation would never become a popular method, that sooner or later it would receive universal condemnation and thus reach its final and well deserved destination—the lumber room of obstetric instruments

DISCUSSION

Dr. Henry Schwarz, St. Louis, was glad to hear Dr Zinke's experience in reference to Duhrssen's vaginal cesarean section, because personally he had had no experience with that method He could conceive of exceptional cases of eclamptic convulsions or of placenta previa in which cesarean section might be justifiable in proper hands and under proper surroundings As a rule, in eclamptic convulsions Duhrssen's method should be the one of choice, and there could be very few exceptions where conservative cesarean section was indicated No one would maintain in a case in which the placenta was eccentric, marginal or low seated, with hemorrhage, that cesarean section should be resorted to Whenever one made a diagnosis of central placenta previa, the cervix was so far dilated that no one would think of doing anything except to deliver the child through the natural way He thought Bossi's dilator had a limited sphere of usefulness

Dr James F W Ross, Toronto, Ontario, said he had done cesarean section three times, in each case with the recovery of the mother and the loss of the child The question between cesarean section and the Porro operation had been pretty well settled and the conclusion reached that the Porro operation, when cesarean section failed enabled one to control hemorrhage The last Porro operation he did was in a case reported to the society where a woman delivered herself up through the vagina into the abdominal cavity, and the fetus and placenta were forced through an enormous rent in the posterior vaginal cul de sac In this case he did a Porro operation to control hemorrhage He had operated on two cases of rupture of the uterus with recovery, after having performed the Porro operation, by gauze packing, and he thought this operation in these cases should not be adopted unless there was hemorrhage that could not be controlled

Dr O J Elbrecht, St Louis spoke of Duhrssen's incisions, saying that he had had three or four of these cases, in which he had resorted to Duhrssen's incisions with good results

Dr J Henry Carstens called attention to the point that many practitioners were too anxious to dilate the cervix in the class of cases under discussion He had seen them use rubber dilators and dilators of all kinds in working around the uterus for two or three days at intervals, and then finally had to send for someone to help them out of difficulty Such practitioners wanted to know whether they should do this or do that In some cases, after he had been called in consultation, he had found that the women were not in labor at all He thought many of the members of the society had had similar experiences It was a mistake to suppose that because a woman had a little pain at the approach of labor that she was actualy in labor

Dr Eugene J Brown Stanford, Ky, said in these days of aseptic surgery with the results we are having with mechanical and manual dilatation, cesarean section would become more popular and evidently in selected cases more lives to both mother and child would be saved than by other methods He had the pleasure of witnessing the operation by Dr Deaver, referred to in the paper It was performed on February 23 of this year The simplicity and ease of the operation impressed him very deeply The mother and baby got along without any trouble

Dr M W Meyer Columbia Mo spoke of the use of the Bossi dilator While he admitted there were many men who used this instrument, and recommended its use in cesarean section those who were not radical in the matter had determined that it was not an instrument to be used in such cases In fact, one had to go back to the old methods of delivery in cases of placenta previa, namely, to resort to the use of tampons One could accomplish more with them than in any other way

Dr Zinke said that whatever he may have said or written in the past on this subject and presented to day came from a motive simply to do good in the future, and to get rid of a certain method of practice in obstetrics which had been the means of rendering families unhappy and because he honestly believed that there was great room for improvement in this practice in spite of all that had been said against it

Vaginal Cesarean Section in Grave Cases of Puerperal Eclampsia

Dr J Henry Carstens, Detroit, said that mild cases of puerperal convulsions ordinarily could be controlled by the treatment generally advocated for this class of cases, but that there was a serious, grave form of puerperal eclampsia where one convulsion followed another in quick succession, and the patient finally died in spite of ordinary, and sometimes even heroic treatment This severe variety of eclampsia could generally be subdued by immediate delivery This was accomplished generally by manual dilatation, the use of powerful steel instruments, like that of Bossi, but what was better still was the operation called the vaginal cesarean section, which enabled the obstetrician to deliver the woman in about five minutes with little or no danger In conclusion he stated that 1, in grave puerperal eclampsia, as a rule, prompt delivery will save the patients, 2, that manual effort with the fingers and the hand was too slow, 3, powerful steel dilators were not always at hand, and often caused serious injuries 4, vaginal cesarean section enabled the obstetrician to quickly and safely deliver the woman

An Unusual Case with Many of the Symptoms of Appendicitis.

Dr Magnus A Tate, Cincinnati, narrated this case which was of interest because 1 It presented an unusual history 2 The symptoms and history of the case following scarlatinal nephritis led him and others to suppose that probably they were dealing with a case having appendicitis as a complication 3 The patient urinated regularly and at no time was there a dribbling of urine 4 The presence of adhesions and the enlarged bladder with its thick walls had only problematical causes, not explained satisfactorily by the history of the case

The patient, a boy aged 7 was attended by Dr I Linss of Cincinnati for an ordinary attack of scarlet fever from Feb 25 to March 18, 1904 March 21 Dr Linss was called to see the boy on account of a swelling of the feet and hands On the morning of April 1 all edema had disappeared, urine highly colored, but normal in quantity, with no sugar, albumin or casts That afternoon the patient had a chill, vomited, and was suffering with a pain in the abdomen Temperature, 99 5, pulse, 90 April 5, the patient had two more attacks of vomiting Pain in the abdomen was constant, and he had not slept for twenty four hours, temperature 102, and pulse, 130 Dr William Johnson saw the case with Dr Linss, and on examination of the abdomen they found an uneven swelling which extended to the umbilicus and over the right lumbar region On palpation exquisite tenderness over the appendix was elicited A diagnosis of appendicitis was made, but further consultation was asked for The next day April 6, Dr Tate was called When he saw the patient, six days after the initial vomiting spell and chill, the child had been crying and moaning day and night, and could not sleep, temperature, 102, pulse, 132, very irregular, abdomen swollen, especially on the right side, and such marked tenderness that the child screamed if the slightest pressure was made over the region of the appendix Bowels constipated and the urine highly colored The following day there was no improvement, the pulse even worse, temperature remained at 102 Before placing the child on the operating table a bed pan was placed under him and he passed nearly a pint of urine Chloroform was administered, and an incision was made on the right side two inches in length, over the most prominent portion of the swelling It revealed a dark colored sac and a number of adhesions The incision was lengthened to three inches Some adhesions were broken down with the finger, but a few of them were so firm that they had to be cut The enlarged opening gave a field of about two inches to work in, and the sac in appearance was not unlike that of a gangrenous bowel They were at a loss to say exactly what it was, and as adhesions limited the field, gauze was packed about the opening, the child turned to the right side, and a half inch cut was made into the sac A dark green fluid spurted out which had a strong, heavy odor of stale urine About two quarts of fluid was evacuated and the finger into duced into the sac, which proved to be the bladder The opening in the bladder was sewed up, adhesions binding the bladder on to the abdominal wall and on the right side to the large and small intestines were broken up, and the enlarged thick walled bladder dropped back into the abdominal cavity The appendix and appendiceal region, except for the presence of some adhesions, were normal An opening was left in the abdomen for gauze drainage, and the rest of the wound closed up The subsequent history was that the bladder was emptied by means of a retention catheter for forty eight hours, after that catheterization night and morning for three days There was a gradual decrease in pulse and temperature, and in seven days both were normal On the third day a quantity of fluid drained out through the opening, but this gradually ceased, and on April 23, sixteen days after operation, the abdominal wound had closed, and the patient is now in good health

Gunshot Wound of the Abdomen

Dr John D S Davis, Birmingham, Ala, reported a case of gunshot wound of the abdomen, with eighteen perforations, in which he resorted to intestinal resection of five feet seven inches, with use of the metal button, followed by recovery of the patient. The patient, a woman, 23 years of age, while attempting to place a rifle in the rack on the wall, the gun was discharged with the muzzle about eight inches from the abdomen The bullet, a 32 caliber, entered in the median line mid way between the umbilicus and the symphysis pubis, ranging backward, upward and to the right, and was deposited in the muscles of the back on the right side The ball in traversing the abdomen made eighteen perforations of the gut, and two cuts in the intestine that went to the mucous membrane Sixteen of the perforations and the two sero muscular wounds were in the small intestine, and two perforations in the transverse colon The bullet cut two mesenteric arteries, which caused a large amount of blood to collect in the abdomen Patient was shot at 4 30 p. m, Feb 2, 1904, and was brought a distance of eighty miles on a freight train to Birmingham, by her physician, Dr W O Watson, and carried to Hillman Hospital At 9 o'clock Dr Davis saw the patient and had her prepared for section Temperature at this time was 102, and pulse 130 She probably had fever at the time she was shot A seven inch incision was made in the median line, a large quantity of blood turned out, and the bleeding vessels controlled by hemostatic forceps The two perforations in the transverse colon were so near the mesenteric border that he stripped up the mesenteric serosa and turned the mesenteric border in as though the two openings, one on each side, had been one large opening, including mesenteric border, and closed with interrupted silk sutures He then brought the mesenteric folds back and sutured over the wound Four perforations and two sero muscular cuts in the small intestine were turned in and closed with small loop silk sutures Two perforations were situated so close together that they had to be closed by flexing pouching or looping the mesenteric border, the bowel being bent on its convexity so that the two wounds could be closed as one large wound by interrupted longitudinal loop sutures—suture with axis of bowel There were two other perforations that could have been closed by suture, but the openings were between two mesenteric perforations on one side and eight on the other, and he thought it better to lose one more foot of intestine than to do two resections He resected that part of the intestine containing the ten mesenteric perforations (sixty seven inches), including the two large perforations in the convexity of the ileum and closed with the third sized metal button The resected bowel and its mesentery were removed, the vessels ligated, and the gap in the mesentery closed with interrupted silk sutures The abdomen was flushed with hot normal salt solution plain gauze drainage was used, and the abdomen closed with through and through silkworm gut sutures The operation lasted one hour and a half Drainage was removed on the second day Patient passed the button on the twenty first day and left the hospital March 1, 1904 A week later she was doing housework, and was perfectly well

Miscellany.

TRAVEL NOTES

OUR POSSESSION IN SAMOA FROM A MEDICAL STANDPOINT

NICHOLAS SENN, M D

CHICAGO

Auckland, New Zealand, July 25

We landed at Pago Pago on Thursday, July 21, at 6 30 a m The natives were on hand to welcome us, and many a greeting was expressed in the euphonious word "*talofa*" (love to you) The moment the ship was anchored in the harbor a fleet of canoes surrounded it and their brown inmates in native attire—men whose only garment was a breechcloth, women in the loose, comfortable Mother Hubbard calico dress, children with no clothing incumbrances of any kind, all of them with a copious growth of jet black long curly hair freely exposed to sun light and breeze, with upturned faces and large, gentle, imploring coal black eyes—were soliciting patronage for the products of their charming island Gaudily painted tapa cloth made of the bark of a tree, coral beads, baskets of various designs and sizes, shells and tropical fruits were the principal articles offered for sale The competition between the dusky vendors was not a spirited one, it made little difference who reaped the greatest profits, as in a short time the gain of the morning's sales, according to the customs of the island, would soon be shared equally by all Our time in the harbor being limited to a few hours, I was very anxious to improve every minute in studying the resources of the island, its people and their diseases By previous appointment I was met on board by Dr H E Odell, P A Surgeon U S Navy, the medical officer of the training ship *Adams*, now in the harbor (Fig 1) To this officer I am greatly indebted for many charming courtesies and most valuable information He took me ashore at once in the government launch and on landing introduced me to Chief Pan Pan of the village Aua, who happened to be present, a man highly esteemed by the natives and whites for his excellent character and good judgment His distinctive dress consisted of a long white coat, with shoulder straps of the same color with a narrow border of blue His whole bearing impressed one with the dignity of his office and firmness of his character From the time we entered the harbor until we reached the shore I had looked in vain for the American flag I saw the bare, tall pole in front of the custom house and was wondering what had happened in international politics since I left San Francisco, that it should have been stripped of our colors The information came without asking any questions A few minutes after landing a motley crowd gathered around that pole and presently I had the pleasure of witnessing the hoisting of the American flag (Fig 2) This is a ceremony that takes place every day at 8 o'clock in the morning The moment the Stars and Stripes reached the lofty destination, fluttering in the fresh morning breeze, the native band played our national airs, "My Country, 'Tis of Thee" and "Star Spangled Banner," and the mountains re echoed the strains of the stirring music so dear to the heart of every American The ceremony was an impressive one The native guard, composed of 72 picked men magnificent specimens of physical development, wearing a red turban white sweater and blue trousers, stands at attention with arms at rest The crowd of people, including many children, stood motionless not a word being spoken until the last strains of the music had died away in the soft, balmy air of the tropics when the guard shouldered their arms and marched away to their respective posts of duty in a truly soldierly manner and the crowd dispersed as quietly and silently as it had gathered This beautiful ceremony reminded me that I was on American soil in the midst of the vast trackless Pacific ocean, nearly 5 000 miles from the western limits of the United States

SKETCH OF THE HISTORY OF THE ISLANDS OF SAMOA

Not all the people of the United States are aware of the fact that the beautiful island of Tutuila of the Samoan archipelago is one of our ocean possessions and very few know how it was acquired In making inquiries among officers and passengers of the *Sierra* regarding this subject I became satisfied how little there is known about it The history of Samoa, especially the recent part of it, leading up to the time Tutuila was ceded to the United States, is a very interesting one and does not reflect much credit on some of the foreign powers, especially Germany The extent to which Germany meddled with Samoan affairs and the fact that she now owns the two largest islands, Savaii and Upolu, are matters difficult to explain The recent history of Samoa is a tangle difficult to unravel without losing the thread owing to the rapidity of succession of events caused by contending internal political factions, complicated by outside interference Space will permit me only to give a few outlines The Samoan archipelago, composed of not less than fourteen volcanic islands with numerous adjacent islets lies nearly east and west between the parallels 13 31′ S and 14° 31′ S, and longitude 172 45′ W and 168 9′ W The last volcanic eruption occurred in Savii in 1866 The islands were first seen by Roggeveen, but their discovery is generally accredited to Bougainville, who came there in 1768 and stocked them with domestic animals He called them Navigator Islands It is supposed that the islands became populated by Polynesians migrating eastward from Sumatra, via the Philippines and Hawaii by a party of less than fifty in seven canoes Two hundred years later the Tongans invaded the islands and, with the aid of Fijians drove the Samoans into the mountain retreats The hardships endured by constant persecution served to strengthen the Samoan forces, who finally gained the upper hand and cleared the two largest islands, and later all of them, of the invaders Cannibalism was introduced by the Tongans, but was abandoned before the arrival of the explorers The missionaries came in 1833 and one of the first fruits of their indefatigable labor was the conversion of Malietoa, one of the most powerful chiefs, who was christened Davita This event gave rise to a religious wave which soon reached the different islands

Frequent strifes between the different islands and tribes induced the natives to look to the United States as early as 1872 to establish order out of chaos by requesting our government to send Colonel Steinberger of New York as adviser Two years later President Grant granted the request The colonel soon improved the administrative affairs of the islands and had the full confidence of the natives His influence excited the envy of the British and in less than a year he was deported by a British warship, no protest being made by our consul and the unwarranted action had the full sanction of King Malietoa Laupepa. Insurrection followed and the king was deposed From now on the political events followed in rapid succession by the aggressive interference on the part of Germany Talavoa was elected king, but died after a short tumultuous reign and Laupepa again succeeded to the throne only to be again deposed in 1888, when he was exiled by the German fleet Insurrection under the leadership of Malietoa Mataafa again unsettled political affairs At one time the German English and American warships in the harbor of Apia were ready to clear the decks and begin war between Germany on one side against the other two powers, when the great storm swept them out of existence with the exception of the English gunboat *Calliope* Active interference on the part of the United States resulted in the Berlin conference, which declared in favor of Laupepa against the protests of the natives With the assistance of a German and British warship Laupepa defeated the forces of Mataafa near Apia in 1893, who shortly afterward surrendered to the British and was exiled to the island of Jaluit with twenty of his chiefs, where he remains at the present time On the return to power Laupepa abdicated in favor of Mataafa but European diplomacy again interfered and he remained on the throne After Laupepa's death in 1888 came the contest between the exiled Mataafa, who had the German influence, and Tana, the son of the dead king After a number of fierce contests the matter was referred to Chief Justice Chambers, who decided in favor of the heir to the throne Finally Admiral Kautz of the battleship *Philadelphia* interfered and insisted that both contesting parties should lay their claims aside England now withdrew from the contest, leaving the Germans and Americans in the field to dispose of the islands A satisfactory agreement was reached by which, on Nov 8, 1899, the two largest islands, Savaii and Upolu, were ceded to Germany, and Tutuila with its magnificent harbor became the property of the United States

OUR SAMOA ISLANDS

Out of the internal dissensions and whirlpool of foreign interventions arose for us, phoenix like, Tutuila, the most beautiful and, from a strategic standpoint, the most important of the Samoan Islands Pago Pago harbor is land locked, with an average of thirty fathoms in depth and sufficiently large to give protection to a fleet of from six to eight of the largest men of war, with a strip of land belonging to it amply large for government buildings, barracks and coal sheds The harbor is hemmed in by mountains on all sides, from 1,500 to 2,500 feet high, except the narrow gateway communicating with the ocean These mountains form a safeguard against any hurricane, no matter how severe it might be The entrance is so narrow that a few mines and a battery on the high hills on each side could keep the largest naval force at bay The island is 19 miles long and 230 in circumference A number of islets belonging to it and included in the treaty stretch along the same east and west line, the farthest about sixty miles away The main and adjacent islands are forest clad, without a bare spot in the dark green carpet, extending from the shores to the highest mountain peaks The primitive forests have never been disturbed, as the natives have had no use for timber either for themselves or barter The forests are dense, almost impenetrable, and some of the trees, especially at the very summit of the mountains, are of prodigious size and would yield hardwood timber of great commercial value. The rim of lowland at the base of the mountains, when it exists, and the valleys near the shore line, are covered with groves of cocoa palms and wherever a sufficient number of these trees are found a hut or a small hamlet of huts may confidently be looked for The volcanic formation of the entire island is covered with a thick layer of the most fertile black soil, as shown by the size of the trees, the luxuriance of the shrubs and plants and the abundance of nutritious grass The soil and climate are admirably adapted for the growing of coffee, cacao, taro and all kinds of tropical fruits

CLIMATE.

The climate of Tutuila is influenced by the unbroken, dense, virgin forest. We see here a very instructive example of what such forests are capable of accomplishing in the way of securing an adequate rainfall Drought is unknown The rainy season in the Samoan Islands is supposed to be during the first three months of the year, but in Tutuila it rains more or less throughout the year, rendering the atmosphere damp The rainfall last year, according to Dr Odell, reached nearly 200 inches Every ravine leading from the mountain heights to the sea has its rivulets or small rivers, which drain off the excessive moisture of the saturated soil, furnishing the inhabitants all over the island with a faultless water supply The climate is uniform, the tropical heat modified by sea and land breezes The temperature seldom rises above 85 degrees F and is rarely less than 72 degrees F although on rare occasions the thermometer has registered as low as 60 degrees F (Odell) The nights are generally delightfully cool The climate is, on the whole, very similar to that of Hawaii

THE PEOPLE

> 'They eat they drink and in communion sweet
> quaff immortality and joy"—Milton

The Samoans are a noble race, simple honest, affectionate peaceable and hospitable The men are splendid specimens of physical development, above average size, and with a courteous and noble bearing I observed several women who were close to the six foot mark and as erect as the poles of a bamboo thicket. I noticed that many of the women and some of the men had dark brown hair, which, I was informed, was the result of a process of bleaching with lime, done either with the

22595

intention of ridding it of its living inhabitants or for cosmetic reasons The women are rather fair looking when young, but lose their attraction before they reach the age of 30 by premature old age and obesity Tattooing among men remains as a national custom. It is done as a ceremony as soon as the boys attain virility and the field of operation corresponds with that part of the body covered by their only garment—the breechcloth—so that in the event anything goes wrong with this, the simplest and oldest dress, they should not appear entirely naked The operation is performed by experts, whose implements consist of a little fine toothed comb made of the tusk of the wild boar, which is fastened to a small stick in the form of a minute rake The teeth are dipped into the staining material, and with blows of a little stick on the blunt end of the comb they are made to penetrate deep enough to drive the stain into the deeper layers of the skin The operation is attended by great pain and lasts, according to the artistic designs employed, from five hours upward The lines of tattooing are exceedingly fine and the patterns are often quite artistic, as I had an abundance of opportunity to observe There is very little crime among the Samoans For four years there has been only one murder in Tutuila with its 6,000 inhabitants The whites never lock their doors What we look on as petty thefts, such as taking away without permission a loaf of bread, a fish or any kind of fruit, is not regarded in the light of crime by the childlike Samoan The next day the neighbor so treated will even up the account in a similar manner So far as the food supply is concerned, the Samoans constitute one great family, giving and taking as occasion may demand, and the stranger is always welcome to more than his share Family life is ideal The father rules supreme, old age is respected, the ties of relationship and friendship are strong No operation can be performed on a Samoan without a previous family council If the father is the patient the sons decide the matter, if any other member of the family is concerned the father alone has the power to object to or sanction the operation The bedside of the sick is never deserted by the immediate members of the family, and anxious relatives and friends are never far away

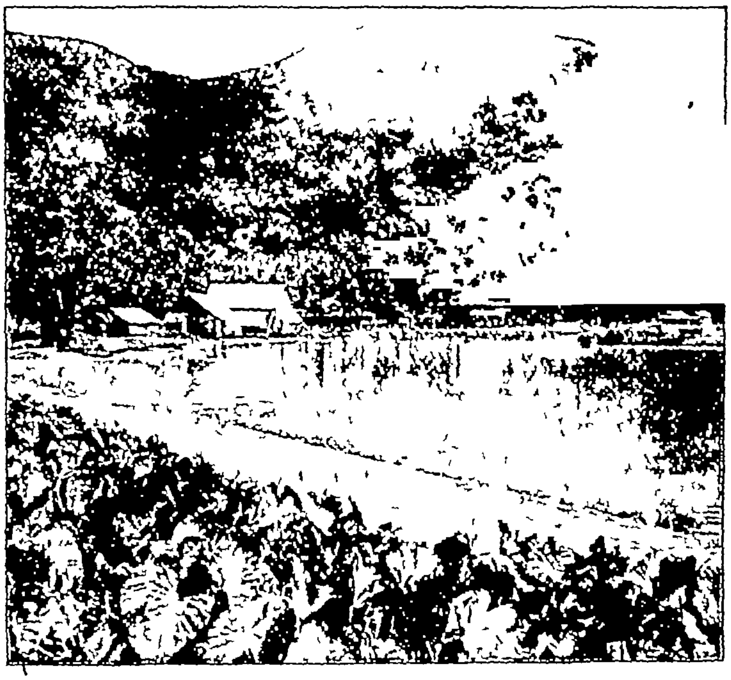

Fig 1 —Tutuila Samoa U S Naval Station

The educational advantages of Tutuila are as yet in their infancy, a defect which should soon be remedied, as the children are very fond of school work The Catholic Sisters have been here, and, as on so many other frontier lines, they are the pioneers in placing within reach of the ignorant children the means of obtaining an education They have opened a school in a village near Pago Pago, which is already filled to overflowing with the little dusky scholars All of the inhabitants are nominally Christians, but religion has failed to wipe out many traces of paganism There are very few legal marriages consummated The native custom still prevails Man and wife consent to live together, and continue to do so as long as the matrimonial sky is clear, but should anything occur contrary to the expectations of the husband the tie is severed by returning the wife to her parents or relatives The children are always provided for Unless other arrangements are made which are satisfactory to both parties, the sons remain with their father and the daughters accompany their mother

The kahuna, or native medicine man, remains, and has not lost his influence among his people They continue their mysterious ceremonies and the use of herbs and roots in battling with the diseases they are called on to treat The remarks of Father Damien concerning the native doctors of Hawaii apply to the kahunas of Samoa "We have to fight their doctors, who are generally nothing but sorcerers In cases of sickness idolatrous sacrifices are still in use All diseases are attributed to mysterious causes It is very hard to disabuse these poor people of such superstitious notions" Superstition remains unshaken by the teachings of the gospel, a strong proof of the truth that

> "Nothing has more power over the multitude than superstition, in other respects powerless, ferocious, fickle, when it is once captivated by superstitious notions, it obeys its priests better than its leaders"—Quintus Curtius Rufus

PRESENT FORM OF GOVERNMENT

Our government has very wisely interfered as little as possible with native rule The harbor, with a strip of land belonging to it, is exclusively under the control of the officer in command of the naval force stationed there He is at the same time the commandant of the island, to whom the chiefs can appeal in all matters in which they find it necessary to obtain advice, or when they fail to adjust local difficulties in their respective communities The naval surgeons stationed at Pago Pago have in charge the sanitation of the island and the care of the sick poor natives They have already succeeded in securing for Pago Pago, a village of 1,500 inhabitants, a pure water supply and many other sanitary improvements The greatest fault with the Samoans is their inborn laziness They will not work The government has now under way many improvements, and, although the wages for this part of the world are large, $1 a day, it had to import laborers from other islands to do the work Civilization has rather increased than diminished this inherent repugnance to labor

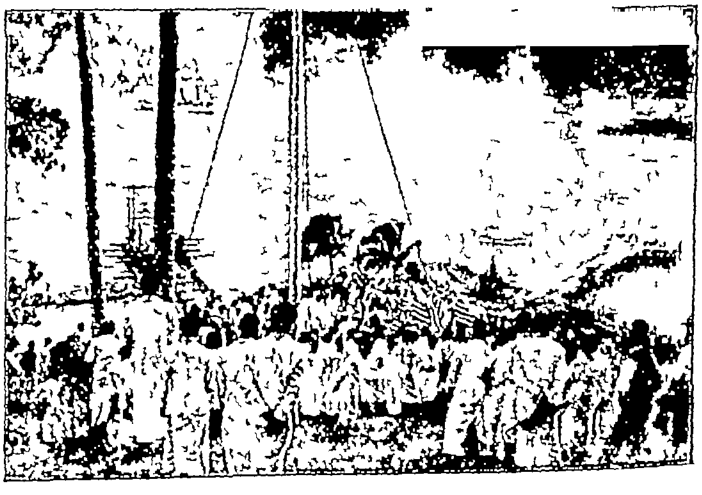

Fig 2 —Flag raising ceremonies

KAVA DRINKING

Kava is the national drink of the Samoans They have not, like our Indians, an ungovernable desire for alcoholic stimulants Kava is the fleshy root of *Piper methysticum*, a succulent plant about four feet in height, with large, long petioled leaves In propagating the plant all that is necessary is to break off one of the leaves at its point of insertion, including the bulbous base of the petioli, and stick it into the moist, rich, black soil Kava drinking is a ceremony Dr Odell was kind enough to give me an opportunity to observe this ceremony in all its details and to sample the product Whenever possible the drink is prepared by a young woman, who always regards the task as obligatory, as well as a privilege, if not of distinction The first young lady that passed Dr Odell's bachelor quarters was called in, and she went through the entire performance with a grace and elegance that showed that she was no novice in that part of her domestic functions Formerly the root, fresh or dried, was chewed by young women Now the dried root is crushed on a stone, and the coarse powder is placed into a shallow bowl of hard wood, supported on very short legs, the pride of every Samoan family, it is to them what the samovar is to the Russians After pouring cold water on the pulverized root it is stirred vigorously with both hands for about five minutes, when the straining is commenced with a swab of bark fibers, which is continued until all coarse particles are removed from the soapy looking liquid the entire time required being about fifteen minutes The liquid has a peppery, rather pleasant taste. It is served in cups of carved cocoanut shell This drink suits the place and climate better than any other beverage In larger quantities it produces a form of slight intoxication in moderate quantities it is a diuretic and slight soporific

NATIVE HOUSES

The natives remain true to their original architecture in the construction of their houses The houses are circular, open, the round dome like thatched roof resting on poles The rafters are made of the bread fruit tree, held together and fastened to the upright poles with an intricate lacework of bark and twigs The ground is covered with gravel The bed consists of tapa mats, and the pillows are bamboo sticks, as large as the arm of an adult, supported by props at each end, about four inches in height The cooking is done outside As there is no other furniture in the house the domestic duties of the female part of the family are certainly of the simplest kind The tapa cloth is made of the thick, soft bark of a tree, it is pounded into thin sheets, dried and painted in figures most pleasing to its future owner It is the principal article of barter, and its abundance or scarcity constitutes the wealth or poverty of the family These open houses and the frugal diet are most conducive to the preservation of the native's health Indoor air, combined with the inherent inactivity of the natives, could not fail in multiplying disease and increasing the death rate

DISEASES

Samoa, like all islands of the South Pacific, has lost its full share of population from the effects of the infectious diseases introduced by the whites, notably measles, smallpox and tuberculosis Vaccination is now generally practiced by the naval surgeons, and the natives subject themselves willingly to this prophylactic measure The spread of infectious diseases among the natives is favored by their habits Their affectionate nature and the strong ties of friendship bring relatives, friends, communities and different villages in continuous and frequent contact with the afflicted, and in this manner infection is carried in all directions, and in a remarkably short time by progression from place to place will reach the most remote parts of the island. I imagine that any efforts to cut off free communication between the sick and well would appear as an infliction of cruelty to the natives, and would meet with their displeasure, if not persistent opposition It is this free intercourse among the people that accounts for the rapid spread of measles and other acute infectious diseases over the entire island The natives have absolutely no comprehension of the importance, much less of the necessity, of enforcing sanitary precautions

Tuberculosis affects most frequently the lungs, as this organ becomes most frequently predisposed by catarrhal affections, which are very common, next in frequency are the bones and joints, and lastly the lymphatic glands and intestinal canal Leprosy is unknown in Tutuila On the other hand, elephantiasis is very common It is estimated that of the male population over forty years of age 50 per cent are suffering from this disease It attacks in preference the lower extremities but not infrequently the upper become involved, and scrotal elephantiasis is by no means rare Dr Odell has operated on a number of cases of scrotal elephantiasis successfully, in which the mass removed weighed twenty and more pounds The disease is much more common in men than women, undoubtedly because they are more frequently the subject of lesions, which determine infection The disease is occasionally met with in children less than ten years of age, and not infrequently in young men at the age of twenty There are only about 50 whites in the island, and one of them, a German had been a resident for thirty two years He married a native woman and raised a large family of children He is now 57 years old, and contracted the disease twelve years ago It affected the right leg, pursued a somewhat acute course and recently a complicating affection of the knee joint made an amputation of the thigh necessary He made a good recovery and will leave the hospital in a short time for his island home This case, like so many others proves that a prolonged residence in a tropical climate renders the whites susceptible to infection Skin affections are very prevalent in the island, more especially ulcers of the leg The lack of clothing and footwear is undoubtedly largely responsible for this, exposing the parts to all sorts of mechanical irritation in walking through the dense bush and along the stony, pebbly shore These ulcers yield promptly to treatment by rest, and the local use of antiseptics Another common affection is the so called tropical abscess, a deep seated, somewhat subacute phlegmonous inflammation, attended by only slight constitutional disturbances It is undoubtedly the result of infection through surface lesions which are so common, that is, the entrance into the tissues of some mild form of pus microbe through a surface infection—atrium These abscesses heal very promptly after incision and drainage The frequency with which hydrocele is met with is attributed by Dr Odell to *Filaria sanguinis* infection, but he has encountered no difficulty in effecting a radical cure by the usual operative treatment Among the skin affections yaws figures very largely Dr Odell showed me a little girl suffering from this disease The lips and lower segment of the face were covered with very super

Fig 3—Tamasese Fine specimen of Samoan

intention of ridding it of its living inhabitants or for cosmetic reasons The women are rather fair looking when young, but lose their attraction before they reach the age of 30 by premature old age and obesity Tattooing among men remains as a national custom. It is done as a ceremony as soon as the boys attain virility and the field of operation corresponds with that part of the body covered by their only garment—the breechcloth—so that in the event anything goes wrong with this, the simplest and oldest dress, they should not appear entirely naked The operation is performed by experts, whose implements consist of a little fine toothed comb made of the tusk of the wild boar, which is fastened to a small stick in the form of a minute rake The teeth are dipped into the staining material, and with blows of a little stick on the blunt end of the comb they are made to penetrate deep enough to drive the stain into the deeper layers of the skin The operation is attended by great pain and lasts, according to the artistic designs employed, from five hours upward The lines of tattooing are exceedingly fine and the patterns are often quite artistic, as I had an abundance of opportunity to observe There is very little crime among the Samoans For four years there has been only one murder in Tutuila with its 6,000 inhabitants The whites never lock their doors What we look on as petty thefts, such as taking away without permission a loaf of bread, a fish or any kind of fruit, is not regarded in the light of crime by the childlike Samoan The next day the neighbor so treated will even up the account in a similar manner So far as the food supply is concerned, the Samoans constitute one great family, giving and taking as occasion may demand, and the stranger is always welcome to more than his share Family life is ideal The father rules supreme, old age is respected, the ties of relationship and friendship are strong No operation can be performed on a Samoan without a previous family council If the father is the patient the sons decide the matter, if any other member of the family is concerned the father alone has the power to object to or sanction the operation The bedside of the sick is never deserted by the immediate members of the family, and anxious relatives and friends are never far away

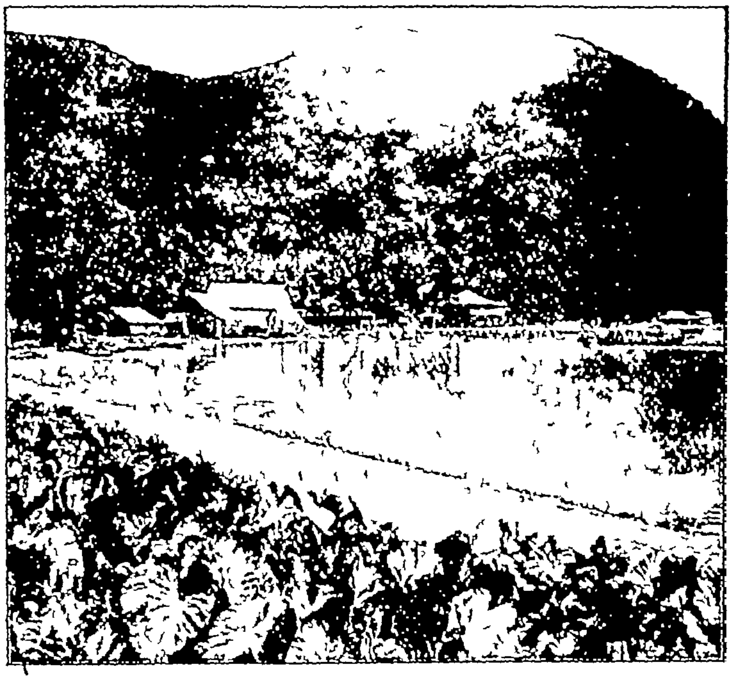

Fig 1 —Tutuila Samoa U S Naval Station

The educational advantages of Tutuila are as yet in their infancy, a defect which should soon be remedied, as the children are very fond of school work The Catholic Sisters have been here, and, as on so many other frontier lines, they are the pioneers in placing within reach of the ignorant children the means of obtaining an education They have opened a school in a village near Pago Pago, which is already filled to overflowing with the little dusky scholars All of the inhabitants are nominally Christians, but religion has failed to wipe out many traces of paganism There are very few legal marriages consummated The native custom still prevails Man and wife consent to live together, and continue to do so as long as the matrimonial sky is clear, but should anything occur contrary to the expectations of the husband the tie is severed by returning the wife to her parents or relatives The children are always provided for Unless other arrangements are made which are satisfactory to both parties, the sons remain with their father and the daughters accompany their mother

The kahuna, or native medicine man, remains, and has not lost his influence among his people They continue their mysterious ceremonies and the use of herbs and roots in battling with the diseases they are called on to treat The remarks of Father Damien concerning the native doctors of Hawaii apply to the kahunas of Samoa "We have to fight their doctors, who are generally nothing but sorcerers. In cases of sickness idolatrous sacrifices are still in use All diseases are attributed to mysterious causes It is very hard to disabuse these poor people of such superstitious notions" Superstition remains unshaken by the teachings of the gospel, a strong proof of the truth that

> "Nothing has more power over the multitude than superstition, in other respects powerless, ferocious, fickle, when it is once captivated by superstitious notions, it obeys its priests better than its leaders"—Quintus Curtius Rufus

PRESENT FORM OF GOVERNMENT

Our government has very wisely interfered as little as possible with native rule The harbor, with a strip of land belonging to it, is exclusively under the control of the officer in command of the naval force stationed there He is at the same time the commandant of the island, to whom the chiefs can appeal in all matters in which they find it necessary to obtain advice, or when they fail to adjust local difficulties in their respective communities The naval surgeons stationed at Pago Pago have in charge the sanitation of the island and the care of the sick poor natives They have already succeeded in securing for Pago Pago, a village of 1,500 inhabitants, a pure water supply and many other sanitary improvements The greatest fault with the Samoans is their inborn laziness They will not work The government has now under way many improvements, and, although the wages for this part of the world are large, $1 a day, it had to import laborers from other islands to do the work Civilization has rather increased than diminished this inherent repugnance to labor

Fig 2 —Flag raising ceremonies

KAVA DRINKING

Kava is the national drink of the Samoans They have not, like our Indians, an ungovernable desire for alcoholic stimulants Kava is the fleshy root of *Piper methysticum*, a succulent plant about four feet in height, with large, long petioled leaves In propagating the plant all that is necessary is to break off one of the leaves at its point of insertion, including the bulbous base of the petiole, and stick it into the moist, rich, black soil Kava drinking is a ceremony Dr Odell was kind enough to caution being required in judging the amount of blood to be withdrawn

Hiccough

The *Med Times* suggests the following Chloral is perhaps the most generally useful drug in idiopathic hiccough, given to an adult in doses of ten grains (or even twenty grains) every hour until from sixty to eighty grains have been used If after four or five hours the spasms still continue, it will be inadvisable to go on with the chloral Many times a sharp counter irritation on the surface of the epigastrium will stop the attack, used with or without the chloral internally The simple act of sneezing will sometimes promptly check hiccough

Cerebrospinal Meningitis.

Berg, in a recent number of the *Med Record,* discusses the clinical and other features of the recent epidemic of this disease, and gives the following outline of treatment

LUMBAR PUNCTURE

The lumbar puncture is made and repeated only when, after a period of improvement, the temperature again rises, and symptoms of increased intraspinal and intracranial pressure occur, such are total abolition of the patellar reflex, slowing of the pulse, Macewen's symptom, increase in the Kernig phenomenon, increase in the delirium and stupor If the cerebrospinal fluid flows from the canula in a continuous stream under tension the withdrawal of 15 to 30 c c of fluid will do much good. If it escape drop by drop, or if the puncture be a dry tap, there will be no therapeutic result. Sodium iodid is given in from 5 to 10 grain doses every three hours for a child over a year old, and from 15 to 20 grains every three hours for an adult In adults, also mercuric ointment in doses of 15 grains is rubbed into the back of the neck twice daily until the gums are red In older children the amount used is about equal to the size of a bean, and rubbed in several times a day In children with open fontanelles the oleate of mercury in proper doses is rubbed into the anterior fontanelle

FEVER.

When below 102 F no treatment is required, above 103 F use a warm bath at 80 F in which the patient remains five minutes, the temperature of the bath is then raised to 90 F, and the patient is allowed to remain five minutes more. The bath not only reduces the temperature, but induces quiet and rest

GENERAL CARE

1 Large, light, airy room with thorough ventilation

2 Care and cleanliness to avoid the occurrence of bedsores

3 Cleanliness of the nose to prevent deeper infection through the nasal cavities

4 Daily examination of the ears, a timely paracentesis of the drum membrane in suppuration of the middle ear may prevent a subsequent mastoid disease

5 Care of an incipient conjunctivitis to prevent a panophthalmitis, the eyes should be protected from the light by means of a shade and not a darkened room

Pulmonary Tuberculosis.

Pottenger, in a recent number of *Amer Med*, discusses the rôle of the general practitioner in the prevention of this disease There are three factors in the etiology of tuberculosis which must be understood in order to properly and intelligently administer prophylactic treatment

1 Soil —There will be no disease even though the bacilli be present unless the soil is suitable, the body cells must lose their natural resisting power Under normal conditions the cells are very resistant to the growth of the tubercle bacilli This fact is proven by the great prevalence of the tubercle bacilli and the great number of healed foci found in postmortem examinations which were of no clinical significance, in fact were never recognized before death

2 Bacilli —It is an established fact that the tubercle bacillus is the specific cause of tuberculosis, yet it is very questionable if it is capable of producing the disease in a healthy individual, unless it be from a very virulent culture or the inoculation be one of great numbers

3 All influences which lower the normal protective power of the cells must be carefully guarded against (*a*) By living a natural hygienic life Sunshine, fresh air, good food, cleanliness, proper regard for the functions of the various bodily organs, and good habits will do much toward preserving the natural defensive powers of the body cells (*b*) Avoid those things which actually lower vitality, such as overwork, especially under bad hygienic conditions, overcrowding, in rooms badly ventilated and poorly lighted, underfeeding, excesses, especially alcoholic and venereal, disease, mental disturbances, worry over real or imaginary troubles and depression from other causes

The author elaborates further by advocating that a maximum number of hours should be designated as a day's work, varying according to the ages of the workers and the character of work done Workshops, offices and dwellings should have certain requirements as to floor space per occupant The poor should be encouraged by low rents and cheap and rapid transportation to reside in the suburbs Greater care should be taken by the physician in the after care of those diseases which are known to be frequently followed by tuberculosis, e g, la grippe, typhoid fever, and measles

DESTRUCTION OF THE BACILLI

This is largely a matter of education and honor, and its accomplishment depends almost entirely on the medical profession Physicians should have an accurate knowledge of the method of spread of the infection, which should be combated by instruction, by the family physician in the well to do classes, as to the careful disinfection of the sputum and other bacillus bearing discharges *The patient should be told of the* nature of the disease in order to gain his intelligent co operation The great majority of cases are among the poorer classes, and the instruction of them should be placed in the hands of the proper health officers In order for the health officer to obtain results he should assist and be assisted by the family physician

1 Cases should be reported to the health authorities

2 Occasional circulars should be issued by the health department and sent to the physicians

3 Instruction of the poor should be done by the health authorities, in matters of hygiene and disinfection Several assistants should be appointed who, with the help of a corps of trained nurses, should visit the homes of the tubercular poor and make them hygienic This work could be materially aided by the establishment of a free dispensary for tuberculosis Such a dispensary to provide sputum cups and disinfectants and it would be an act of mercy if such foods as milk and eggs could be given to those who were in need of them

EARLY DIAGNOSIS

Of the great advantage of early diagnosis the author says "It is conservative to say that if the disease were diagnosed, as it can be, in its very incipiency, at least 75 per cent could be restored to health by intelligent treatment" Therefore, examine all suspicious cases

Medicolegal.

Crying as Evidence of Injury—The Supreme Court of Alabama says, in Montgomery Street Railway Company vs Shanks, a personal injury case brought by the latter party, that crying is often symptomatic of pain, and, in connection with the other evidence of actual hurts received by the plaintiff, the fact that she cried all the afternoon of the accident was admissible in evidence as of the essential circumstances of the injury, as was also the fact that she complained of pain the next morning

Entitled to Compensation for Pain from Operation—The Supreme Court of Michigan says that, in the personal injury case of Beattie vs City of Detroit, testimony was allowed to be given as to the cost of an operation The jury were also instructed that the plaintiff was entitled to compensation "for the pain she may suffer from an operation, if an operation is deemed necessary" The court holds that there was no error in this, it being the opinion of the physicians who testified in the case that the injury would not yield to medical treatment, but could be cured by surgical operation

Drinking of Liquor Before Commission of Crime—The Supreme Court of Iowa says, in the homicide case of State vs Busse, that the crime charged involved the condition of the defendant's mind at the time of the killing and evidence of intoxication could be considered by the jury in determining his mental condition But the court goes on to say that it knows of no authority holding that the mere fact that an offender drank liquor shortly before committing the crime will constitute such evidence of intoxication as to require the question of its effect on his mental condition to be submitted to the jury It is the mental confusion produced by liquor which is receivable on the question of intent of premeditation and not the fact of liquor having been taken, for it is a matter of common observation that one man may drink a considerable quantity of liquor without being affected thereby mentally or physically while another may be seriously affected by a small drink

Expert Evidence and Privilege—The Supreme Court of Missouri Division No 2, says, in the personal injury case of Holloway vs Kansas City that it was insisted that there was error in admitting in evidence the expert opinion of the plaintiff's physicians as to the cause of her physical condition based on the previous history of her case as they learned it from her, that the correct method is to prove cause by hypothetical question based on facts in evidence That the opinion of an expert witness is permissible when based on his personal knowledge of the matter under investigation or on competent evidence in the case, or on both, the court says is well settled but the question here was whether a physician who testifies as an expert should be allowed to express his expert opinion based on the previous history of the patient as he learned it from her personally in consultation with her in respect to her ailments The conclusion is that it was error to allow an expert witness to give his opinion based on the history of the plaintiff as he learned it from her in diagnosing her case or while treating her The court says that the statements of the plaintiff with respect to her past physical condition were mere hearsay, and should not have been considered by the expert in expressing his opinion as a witness as to her physical condition at the time of the trial The decided weight of authority and the better reason support this contention But a conversation between a patient and physician in regard to the former's doctor bill or in regard to a contemplated lawsuit, the court holds is not privileged, it not being "information necessary for the physician to enable him to prescribe for such patient as a physician or do any act for him as a surgeon" within the purview of the statute That the plaintiff could not sever her privilege and waive it in part and retain it in part the court also thinks clear And, if she waived it at all then it ceased to exist That she did so waive it when she testified that a physician examined her though not very thoroughly, and asked her about it, and she told him, and he examined her womb and back is deemed too plain for discussion However, such waiver should be restricted to such information as the physician acquired from her while attending her in a professional character and which information was necessary to enable him to prescribe for her as a physician or to do some act for her as a surgeon and it is manifest that a conversation in regard to a contemplated lawsuit, or the plaintiff's doctor bill, did not come within the provision of the statute But the court is not to be understood by these observations as meaning or intimating that the physician was not competent to testify as a witness to what the plaintiff said to him, if anything in regard to bringing suit against the city for damages, and that if she would go into it they would be able to fix up his bill against her Such statements were not within the meaning of the tute under consideration On the other hand, the court does not agree with the contention that because the plaintiff, after testifying that her health was good, had answered, on cross examination, that a physician had treated her for headaches, that she waived protection of the statute, and that the defendant had the right to the evidence of the physician for the purpose of contradicting her

Vested Right of Physician to Payment as Per Contract—The Supreme Court of Michigan says that, in the case of Kapp vs Board of Auditors of Washtenaw County, the board of health of Freedom township, in said county, made a written contract to pay for the care of indigent persons affected by contagious diseases $10 per visit and 25 cents per mile going After the services in question were rendered, but before the bill therefor was allowed, the legislature passed an act, giving it effect March 13, 1903, which provided for a change in the law giving the boards of supervisors authority to pass on the reasonableness of claims for services in caring for indigent persons, by direction of the board of health, whereas, before the allowance by the local board was usually final and conclusive on the board of supervisors By reason of this the board of auditors refused to allow and pay the bill contracted in this case as above The Supreme Court says that it was unimportant whether the township board of health might properly agree in advance on the price to be paid for such services or not, for the service was rendered at the request of that board, and the bill was audited and allowed by it Had this allowance been made before the act took effect, it is clear that the board of auditors must have paid the bill, and that the physician's right could not, in such case, have been affected by the legislature Did the fact that the allowance was deferred until after such act took effect justify the board of auditors in its action? The court's answer is that the physician rendered services under a law which made the county liable to pay for them on allowance by the local board The amount was agreed on in advance He had a vested right to such payment when lawfully allowed by the local board and it could not be taken away or impaired by legislation, as it would be if the supervisors were authorized to question its reasonableness To much the same effect is the second decision of the Supreme Court of Minnesota in the case of Comstock vs Board of Commissioners of Lesueur County, where it overrules the decision reported on page 1590 of THE JOURNAL of June 11, 1904 In this second decision it holds that chapter 238, page 378, Laws of Minnesota of 1901, changing the liability for expenses incurred in preventing the spread of contagious diseases from towns and villages to counties, did not change or abrogate contract relations then existing between individuals and such towns or villages A contract existing at the time of the passage of that act, and under which an indebtedness against a village arose may be enforced against it Again, it says that at the time the contract here involved was entered into and the indebtedness incurred—at least the greater part of it—towns and villages are solely liable for all expenses of this kind The rights of the parties became vested and fixed at the time the contract was entered into, and it was beyond the power of the legislature to impair its obligation, as between individual creditor and the town or village, by shifting the liability from the town or village to the county The plaintiff in this action had the right to rely on and seek relief in accordance with the contract between himself and the village

5 Traumatic Emphysema of the Orbit and Lids H F Hansell

6 Contracture of the Neck of the Bladder Thomas G Youmans.

1 **The Nervous Symptoms of Peripheral Arterial Disease**—These symptoms may be either paroxysmal or permanent, either motor or sensory The one constant lesion in intermittent lameness is chronic arteritis Aneurism, especially of the iliac artery, is not very infrequent Intermittent lameness bears some resemblance to angina pectoris Its rarity is apparent rather than real and due to its not being looked for or thought of Patients do not always present a typical clinical picture The most striking thing is the absence of the pulse in the member or members affected Many cases are thought to be rheumatic or neuritic or even neurasthenic Glycosuria is a frequent complication in both slight and severe cases Often the disease resembles paralysis agitans without tremor, without festination and without speech defect but with the wooden face and the waxy rigidity of movement The morbid anatomy of the disease is much disputed Some of these cases are spinal in origin and there is found an overgrowth of the neuroglia and minute areas of softening due to disease of the blood vessels in the spinal cord, but at other times there is only sclerosis of the peripheral arteries with little or no spinal disease

10 *Malignant Disease of the Larynx D B Delavan
11 *Post typhoid Perichondritis of the Larynx L Mayer
12 *The Treatment of Pulmonary Hemorrhage W B McLaughlin
13 *Non operative Treatment of Trachoma Frank J Parker
14 *Malaria. R Cadwallader
15 Practical Hygiene in the Public Schools R S Wilcox

10 **Malignant Disease of the Larynx.**—Delavan's paper indicates the progress recently made in the study and care of malignant disease of the larynx and calls attention to certain special points of treatment which seem of sufficient value to demand investigation and discussion, such as the use of the x ray and other means of producing radiant energy Laryngectomy and tracheotomy are discussed in all their phases, and the author concludes that in properly selected cases early preliminary tracheotomy is without doubt a valuable measure Improved technic special skill and early recognition of the disease will continue to improve the results obtained from this operation

11 **Post Typhoid Laryngeal Perichondritis**—Mayer refers to a case of this kind which was published, in part, last year in which a complete cure was effected by means of intubation The special points of interest in the case are 1 The unusual nature of its origin, a gradually increasing dyspnea requiring a tracheotomy one month after the patient was discharged as cured of the typhoid fever Three months later an O'Dwyer tube was introduced which was worn for six weeks 2 The length of time the tube was worn—for three months continuously 3 The ease of deglutition after an intubation 4 The use of the child's size O'Dwyer tube for a short time toward the last 5 The cure by intubation Nine months after the last extubation the patient's general condition is good, she has increased in weight and attends to her usual duties

12 **Pulmonary Hemorrhage**—McLaughlin's treatment of pulmonary hemorrhage is as follows Immediately on the occurrence of the hemorrhage the patient is given a hypodermic injection of 1/100 grain nitroglycerin and 1/4 grain morphin Adhesive straps are applied to the side of the chest from which the hemorrhage is coming and the patient is instructed to lie on that side Six hours after, if the hemorrhage has ceased, the patient is moved to a summer house which has no sides and is practically out of doors At the end of four days the straps are removed and the patient is given a week of rest cure in the open Seven cases have been treated in this manner, four were of moderate severity and two very severe, one was not severe as to the amount of blood lost in a given time, but the bleeding extended constantly over a period of more than seven weeks, during which time all the coughed up matter was stained with blood In all cases the hemorrhage was promptly and permanently controlled, and in none of these was there any secondary rise of temperature

13 **Trachoma**—Parker says that the cases for operation should be selected carefully, inasmuch as much harm may be done by indiscriminate operation Operation is not a radical cure, but merely a means to a cure and a shortening of the time of treatment Post operative treatment is of the greatest importance, without it there may occur relapses which are as bad or worse than the first attack The general condition of the patient is of importance Proper feeding and out of door life should be urged Adenoids and other hindrances to development should be removed The treatment should be continued until the patient is cured An effort should be made to prevent the spread of the infection and to arouse the patient's interest in doing so For this purpose Parker gives the following printed instructions to his trachoma patients Trachoma is a contagious disease of the eyelids, which if neglected will cause suffering and injury to the sight. To avoid infecting others, those having the disease should observe the following instructions 1 They should have their own towels, handkerchiefs, washcloths and toilet articles, and under no circumstances should they be used by others. 2 They should sleep alone 3 Avoid rubbing or touching the eyes, as the contagion may be carried on the fingers and infect others through articles handled 4 The hands should be cleaned often with soap and water 5 Treatment should be attended to regularly and continued until pronounced cured by the physician Parker's non operative treatment consists of bichlorid rubbing, with the use of one of the organic silver solutions, night and morning in the hard variety, he uses copper sulphate in place of the bichlorid

14 **Malaria.**—Cadwallader gives a summary of our present knowledge of the etiology of malaria, and reports several cases, calling attention to a number of interesting clinical features He believes that a pre requisite to infection, or at least to symptoms, is a watery condition of the blood, and just in proportion to the total fluid in the body will be the severity of the disease

September 17

16 Suggestions on the Medical College Library Eugene F Cordell
17 *Postmortem Examinations for Medicolegal Purposes I L Polozker
18 The Present Condition of Tenontoplasty (Continued) Professor Vulpius
19 *Trachoma and Some Diseases Resembling It James A Nydegger
20 Notes on Uremia Urea and the Urea Tests F L Wachenheim
21 *The Non susceptibility of the Newborn to Measles Edwin F Graham
22 *Insufficient Motility of the Stomach and Its Treatment. Dudley Fulton
23 *Gonorrhea (?) in the Male John Flanagan
24 *Elevation of the Hips in the Treatment of Placenta Previa Alfred King
25 Our Relation to One Another, John M Kennedy

17 **Medicolegal Postmortems**—Polozker believes that it is absolutely necessary that this subject should be taught in medical colleges, and from the practical standpoint only The difference between the medicolegal postmortem and the pathologic postmortem should be emphasized The modern methods of the coroner and the police department in the conduction of a murder case are deprecated, and a remedy for the evil is pointed out

19 **Trachoma**—Nydegger refers to the confusion in diagnosing between trachoma and other diseases of the conjunctiva, such as papillary conjunctivitis and follicular conjunctivitis The subject of trachoma is reviewed in full

21 **Non-Susceptibility of New-born to Measles**—Graham reports a case which he believes shows the non susceptibility of the infant at full term to measles A woman, ill with a well developed case of measles, gave birth to a healthy child presenting no abnormal conditions or symptoms At no time was the child isolated from its mother, it was kept in the same bed, nursed at intervals of two hours, and treated exactly the same as if it were not exposed to the contagion of the measles Although an older child developed a typical case of measles, the infant, six weeks after birth, presented no evidences of having contracted the disease

22 **Insufficient Motility of the Stomach**—*Fulton's* treatment of this condition is hygienic, medicinal and mechanical The diet should be one that spares the motor powers of the stomach, and, therefore, the more feeble the motility the more liquid the diet, especially when there is obstruction of the pylorus The feedings should be small and frequent, although each case is a guide as to the number of feedings per day that should be given The medicinal treatment comprises the administration of 1/24 grain of strychnin, three times a day, dilute *hydrochloric acid, freely diluted*, in 20 or 30 drop doses after meals, teaspoonful doses of burned magnesia and sodium bicarbonate one or two hours after eating when excessive acidity exists Fulton has obtained good results in these cases by giving a pill containing from ½ to 1 grain of creosote, with 1 grain each of pulverized rhubarb and soap Of the mechanical measures, he uses abdominal bandages, lavage and internal faradaization of the stomach Cases which do not improve under this treatment should be relieved by operative procedure before the strength of the patient is entirely spent

23 **Gonorrhea**—Flanagan emphasizes the fact that many cases of suppurative urethritis are diagnosed as specific and subjected to treatment which may prove harmful rather than otherwise Treating a case of *urethral inflammation*, the physician should know exactly the nature of the trouble and use such treatment as the exigencies of the case demand

24 **Placenta Previa.**—King briefly discusses the value of elevation *of the hips in the treatment of placenta previa* The method is also applicable in excision of the rectum and abdominal hysterectomy, gravity operating in these cases as a great blood saver The method is not described in text books It consists in inclining the patient's body to an angle of 45 degrees This is really the Trendelenburg position, with the legs of the patient in the same plane as the body

26—See abstract in THE JOURNAL, xlii, p 1376

27 **Acute Middle-Ear Disease**—For the treatment of this condition Donovan prefers the curette, finger nail or nail curette He considers ether and nitrous oxid far superior to chloroform for anesthetizing infants and young children In older children and adults he uses *cocain*, in *fact*, a single application of 5 per cent may be used safely even in young children To affect a thorough cure, it is necessary to remove all hypertrophied lymph tissues, such as adenoids and enlarged lingual tonsils The prophylactic treatment is all important and should not be overlooked In all *diseases affecting* the nasal pharynx reasonable precautions should be used to avoid tubal infection With the first symptoms of earache he advises the use of heat and dehydrating remedies If these do not produce beneficial results in a few hours, treat surgically When possible with a catheter use a mild continuous stream of hot air early and repeat in eight or ten hours If these measures fail to relieve the symptoms within ten to twenty four hours, make a free incision through the entire drum or extend into upper canal wall, if necessary Use aseptic gauze drainage and outside pad for absorption Patients should never be allowed to suffer for more than forty eight hours and remain exposed to the risks of complication

28 **Incision of the Membrani Tympani**—Packard emphasizes the great value of early incision of the membrana tympani in the treatment of acute suppurative otitis media, and the many advantages possessed by the so-called dry treatment, and by practicing efficient gauze drainage Douching out the ear is distinctly contraindicated, except when it is done by a skilled aurist, who can properly dry the ear after such procedures

29 **Acute Gonorrhea**—Weiss continues his discussion of this subject, the various silver compounds, their advantages and disadvantages, are considered at length The treatment of the mucosa should at all times conform to the microscopic findings

30 33 **Tuberculosis**—These four articles are an epitome of what is known of the questions dealt with in the papers, and serve to emphasize the importance of an early diagnosis, the necessity of careful differentiation between pulmonary tuberculosis and conditions resembling it, and the value of taking complete histories of each case

37 **Neurofibroma of the Acoustic Nerve**—*Fraenkel* and Hunt are of the opinion that the symptoms of *tumor of* the acoustic nerve are so well defined that a diagnosis can be made with practical *certainty* in every case, not only with reference to *its location, but also its nature and comparative size* However, other slowly growing pathologic conditions in the posterior fossa might closely simulate this condition The slow and essentially benign nature of the growth, its non infiltrating character and enucleability all favor surgical interference

But its deep situation at the base of the brain, in immediate proximity to vital centers offers very serious obstacles From personal observation the authors conclude that the surgical technic should be perfected along the following lines 1 The avoidance of undue concussion in the removal of the bone and the enlargement of the trephine opening 2 A method of extirpation by which the tumor could be extirpated without undue manipulation of the surrounding parts 3 The division of the operation into stages, as recommended by Horsley, and celerity of execution

38 **Macrocheilia.**—Eisendrath adds a second case to the literature of macrocheilia due to adenoma of the mucous glands of the lid, the diagnosis having been confirmed by a microscopic examination The case improved remarkably *after operation*, and there has been no recurrence in a year

39 **Lingual Goiter**—Storrs reports a case of lingual goiter, the tissue involved being accessory thyroids at the base of the tongue which are embryonic remnants of the atrophied thyroglossal duct. Only 32 cases of this kind are recorded in the literature, 29 in women and 3 in men These lingual tumors usually are situated on the dorsum of the tongue, generally just behind and below the foramen cecum, but sometimes enclosing it in their growth on the median line, as a rule, but perhaps a little to the right or left In shape they are round or ovoid, their size ranging from that of a cherry to that of a man's fist The tumor is encapsulated and may project about the surface of the tongue or be almost buried in the muscles of this organ There is no inflammation or infiltration of the surrounding tissues, and at operation the tumor is enucleated easily Its surface is covered with the mucous membrane of the tongue, it is smooth and shiny, and in color is darker than that of the surrounding mucous membrane, due to the great infiltration of blood vessels These vessels cover the surface of the goiter and penetrate deeply into its tissue, and cause the profuse hemorrhages which occur at operation. This rich vascularization is of great value in differential diagnosis The tumor may or may not be movable, its consistency is variable The troubles caused by it are purely functional, and these vary with the size of the tumor With one exception, the patients were in the best of health. It has all the characteristics of a benign tumor The prognosis is favorable. The only rational method of treatment is removal, either by the use of the galvano cautery loop or by incision with enucleation The latter operation is preferable and is performed easily The tumor may be reached either through the buccal cavity or through an incision in the suprahyoid region, which may be simple or include the hyoid bone or inferior maxilla

40 **Posterior Incision for Appendicitis.**—Sheldon describes a method by which the appendix is reached through Petit's triangle The patient is placed on the left side and a *large support put under the left loin thus bringing the appendix* nearer the incision by depressing the right side of the pelvis An incision is made from a point one half an inch behind the highest point of the crest of the ileum toward the tip of the twelfth rib The length of the incision depends on the obesity and the body form of the patient The anterior border of the latissimus dorsi muscle is located, freed by blunt dissecting and retracted posteriorly This exposes the outer border of the quadratus lumborum muscle, the lumbar fascia, and the aponeurosis of the transversalis A transverse incision, one half to one inch above the crest of the ileum, is made, beginning at the outer border of the quadratus lumborum and extending forward parallel to the fibers of the transversalis, as far as is necessary to secure sufficient room to operate quickly The subperitoneal fat is pushed aside with the finger, covered with a piece of gauze The peritoneum is opened near the forward part of the incision and the peritoneal incision enlarged in a posterior direction On opening the peritoneum the cecum presents itself in the wound The appendix is amputated in the usual manner and when drainage is not necessary the wound is sutured in layers, *with catgut* and silkworm gut Sheldon has never found it necessary to ligate a vessel during the operation, and seldom has it been necessary to check temporary bleeding with hemostats In clean cases the operation has no advantages over the method ordinarily *employed*, except that it is followed by less shock and abdominal distress than is a laparotomy through an anterior incision In obese cases the operation is more *rapid* and is less likely to be followed by hernia In all cases requiring drainage the operation is preferable to the old method The abscess is *opened* in the most dependent part *and the infected* area can be treated without coming in contact with the omentum or small intestines Retroperitoneal infection is drained much more efficiently than is possible through an anterior incision Sheldon has operated on 58 cases by this method and has found no disadvantages

49 **Urethral Transplantation**—Pringle describes three cases in which defects of the urethra have been treated by grafting portions of the urethra of an ox Two of the patients so treated had sustained a complete and extensive rupture of the urethra in the perineum, the third patient had a hypospadias, *there being* a deficiency of the floor of the urethra for the whole of the penile portion of the channel The operation in each case was a success, the grafted tissue remaining alive and furnishing a patent channel In two of the patients the procedure had to be repeated, but in each *of them, at the time* of the second operation, the tissue which had been grafted on the former occasion was found to be present.

55 *Tumors P Langerhans
56 Communicability of Pneumonia by Contact I Weber

54 **Acute Rheumatism in Children**—Sheffield considers rheumatism in children a grave infection, one that requires active treatment particularly, *in order* to prevent serious complications Rest in bed is the most important therapeutic measure in this direction, and should be enjoined during the entire course of the disease. Dieting he considers to be nothing but a myth During the febrile stage the diet should, of course, be limited to the ordinary "fever diet" In older children he uses the salicylates combined with small doses of pepsin or ingluvin For younger children he prefers aspirin or the salicylates obtained from the wintergreen plant, in doses of 5 grains, to be repeated every two hours the first day and every four hours the following days For the relief of articular pain and swelling the joint should be wrapped in absorbent cotton wrung out of a warm saturated solution of bicarbonate of soda The compress should be covered with oiled silk and a flannel bandage and changed as soon as it becomes dry After disappearance of the acute symptoms the stiffness and lameness generally yield to gentle massage with an ointment containing 1 dram each of oil of gaultheria and ichthyol in 1 ounce of lanolin Later on it is advantageous to supplement the local treatment by gentle general massage The iodids should not be lost sight of in protracted cases

2 **Human Piroplasmosis**—Donovan gives a full description of the maladies as observed by him, the causative animal parasite and the postmortem findings He is convinced of the identity of this disease and kala azar, the exciting cause in both being the same

3 **Epibulbar Melanotic Sarcoma**—Clegg and Hall add two cases of pigmented epibulbar tumors situated at the limbus to the literature on this subject Of 520,523 out patients who have attended at the Manchester Royal Eye Hospital during the last thirty three years, only 3 were cases of pure melanotic sarcoma of the limbus although general 'orbital melanosis" has been noted more frequently One case disappeared after operation, the other 2 recovered completely In 1 case the eye was removed, in the other 2 the tumor was excised Of the latter the one patient remaining under observation regained perfect vision, and is in robust health

5 **Pseudoleukemia in a Child**—Redfern reports a case of pseudoleukemia occurring in a child two years and nine months old, with no history of previous illness The case terminated fatally by syncope after about eight weeks' illness Only the cervical glands were enlarged, but they were not painful or tender on pressure The axillary and anterior mediastinal glands became enlarged later Dyspnea was marked There was unilateral perspiration on the left side of the body, face and limbs The left pupil was more dilated than the right The general nutrition was maintained until death There was no family history of syphilis or tuberculosis The blood condition was as follows Red corpuscles, 4,080,000, leucocytes, 8,000, lymphocytes, 30 per cent , hyalin leucocytes, 10 per cent , polymorphonuclear cells, 68 per cent , eosinophile cells, 2 per cent

9 **Injection of Paraffin in Rectal Prolapse**—Burgess has treated 18 cases of rectal prolapse by the submucous injection of paraffin having a melting point of 111 Of the 18 cases the ages ranged from 3 to 48 years and the size of the prolapse from 1½ to 5 inches in length In all of them the prolapse descended with almost every bowel movement and remained down until replaced Two were associated with excoriation and ulceration of the mucous membrane, 2 had been previously treated by linear cauterization without success, and 2 had recurred after the excision of the lower part of the rectum The injection treatment has been extremely satisfactory in all the cases, not a single instance of recurrence having occurred. Paraffin masses can readily be distinguished after two months, feeling like nodules of cartilage The technic of the operation is as follows The paraffin is kept melted by placing the container in water at a temperature of about 120 The syringe has its barrel covered with rubber to retain the heat longer The instrument is placed in the hot water bath for a few minutes, is then filled with melted paraffin, and replaced in the bath until the moment it is required to be used. The patient is anesthetized and placed in a lithotomy position, the prolapse is drawn out to the fullest possible extent The apex of the prolapse is seized with artery forceps, at three points equi distant along its circumference, so selected that two forceps will be placed anteriorly and the third in the posterior median line By gentle traction the mucous membrane is raised into three ridges forming an equilateral triangle The needle of the syringe is inserted in turn into the middle of each side of this triangle, from 2 to 3 c c. of paraffin being introduced on each occasion As this solidifies the mucous membrane bulges inward, converting the lumen of the

bowel into a more or less tri radiate slit The forceps are removed, the apex of the prolapse is reduced, and the mucous membrane is again seized with forceps about 1½ in from the original apex, as before, except that at this time, two are placed posteriorly, and one anteriorly The paraffin is injected as before, with the result that the lumen of the bowel is again converted into a tri radiate slit, the radii, however, corresponding to the intervals between the radii of the tier above This portion of the prolapse is now reduced and the forceps re applied, as at the first time, and the process is repeated until the anus is reached As a rule, three tiers are sufficient, but in a very long prolapse four may be introduced safely In order that straining may not cause the prolapse to re-descend before the paraffin has firmly set, Burgess inserts a stout silkworm gut suture through the buttocks on either side, tying it firmly over a pad of gauze placed over the anal orifice This suture is removed at the end of twenty four hours No special after treatment is required The patient is kept in bed for four or five days The bowels have usually been allowed to act spontaneously Autopsy shows that the paraffin remains strictly localized to the area of its introduction and undergoes no change However, the masses become encapsulated by fibrous tissue The rectum is fixed firmly in its normal situation, and can not be drawn down to constitute a prolapse even after considerable pressure

14 *Onyalai a Disease of Central Africa A Yale Massey
15 *Antityphoid or Anti enteric Inoculation F Smith

14 **Onyalia**—Under this name Massey describes a disease found among the blacks of Portuguese West Africa It is rarely ever fatal The only clinical evidence is the appearance on the hard palate and buccal mucous membranes of vesicles distended with blood, ranging from one quarter to half an inch in diameter Sometimes these vessels are umbilicated, they can not be emptied easily, they have a tendency to appear in clots There is no fever, the patient complaining only of discomfort in the mouth and a general feeling of lassitude The duration of the disease is about ten days Treatment consisted of the administration of 60 grains of bicarbonate of soda and half an ounce of unpurified codliver oil internally each day Calcium chlorid was not given a trial

15 **Antityphoid Inoculation**—Smith has made a careful study of this question and summarizes his paper as follows

1 Antityphoid inoculation has a distinct value in protecting the human organism from attacks of typhoid fever
2 To obtain the fullest measure of protection the operation should be done say two months before exposure to infection
3 Even when inoculation is performed shortly before exposure to infection it is a beneficial procedure on the whole
4 The protective influence is exerted for some years long enough probably to tide over the most vulnerable age of youth and earlier manhood
5 The protection afforded is in the proportion of 3 to 1
6 The proportion of protection is much less than that of efficient vaccination for smallpox
7 Vaccination against smallpox is about ten times as effective as antityphoid inoculation
8 Typhoid under normal conditions at home and in some foreign stations is not a very common disease such as smallpox used to be
9 Typhoid among soldiers—on active service in most places and when on peace service abroad especially in India, South Africa Egypt, Bermuda Mauritius and Malta—is a very common and fatal disorder
10 Typhoid is a danger to which nurses and hospital subordinates generally are specially exposed.

The final conclusions reached as regards the practical value of antityphoid inoculation are

1 It is not at present of sufficient practical value to warrant its general adoption by the nation at large
2 It is of distinct practical value to any community in which typhoid breaks out in an epidemic form
3 It is of practical value to those who have much to do with typhoid patients
4 It is of utility for general adoption among newcomers in certain special endemic areas abroad, such as some Indian stations and Malta
5 It is of great practical value at all times to soldiers serving in India, South Africa and Malta also but in a less marked degree, in Gibraltar and other places
6 It is certainly of the greatest practical value to soldiers about to take the field in any tropical or subtropical country where typhoid is known to prevail

Medical Press and Circular, London

16 *Preventive Treatment of Scarlet Fever by Isolation (Aggregation) Hospitals H I J Biss
17 Hospital Isolation and Scarlet Fever the Statistical Aspect C K Millard

16 **Preventive Treatment of Scarlet Fever**—Biss calls attention to the fact that isolation of the patient, except in the case of smallpox, has proven ineffectual so far as stamping out scarlet fever is concerned If scarlet fever is to stand a chance of eradication by isolation, a prodigious number of cases of slight sore throat, of anomalous blushes of the skin, of ill defined shagginess of the fingers, must be isolated, or a large proportion of real sources of infection will be left unrestrained This would entail imprisonment and serious loss to many not suffering from scarlet fever, but whose illness could not be diagnosed with certainty Any system that seeks to eliminate the personal element in scarlet fever infection must rest for its success on the separation of all cases, or of such a large percentage that a very sensible reduction in the total number of infections would be apparent Such can never be the case until the diagnosis has improved to such a point that practically all cases however mild, are recognized and dealt with in hospital or at home It is doubtful whether individual elimination is likely ever to be of much service as a prophylactic measure

21 *Burning Foot, or Erythromelalgia Tropica P N Gerrard

21 **Erythromelalgia Tropica**—Gerrard reports six cases of burning foot, or erythromelalgia, a disease of the plantar nervous or arterial supply, which occurs in the natives of the Malay peninsula who are accustomed to work barefooted on roads and plantations It commences, usually, with a "pins and needles" sensation, affecting the soles of the feet It then progresses to an acute burning sensation, which in the majority of cases is so severe as to prevent the patient walking, and frequently necessitates the administration of narcotics to produce sleep In some cases the patient is enabled to walk on the heels with the aid of a stick, while in others no progress nor attempt can be made Although a previous history of malaria can usually be obtained, no history of malaria occurring during the progress of the disease has been found in any case It is possible, therefore, that the disease may be a neuritis of malarial origin in which the blood supply to the nerves implicated may have become cut off by means of a deposit of malarial pigment Another etiologic factor to be considered is "arteriole fatigue" The treatment was varied Some relief was obtained in two cases by immersing the feet in hot water containing a quantity of salt Various liniments and ointments were unsuccessfully tried, and general tonics with or without strychnin, also failed to give permanent relief Narcotics and sedatives of all kinds only relieved the disease for the period of their action

74 Iron Light Treatment of Alopecia Areata Supplement to Article in No 31
75 Karl Weigert Nekrolog

49 Etiologic Diagnosis of Typhoid Fever—Jürgens comments on the facts that healthy persons can shelter the typhoid bacillus, and that typhoid bacilli are liable to be found in the stools of convalescents even long afterward These facts discredit the value of bacteriologic examination The serum reaction is, further, not absolutely reliable evidence in regard to the etiology of a given affection supposed to be typhoid, as its findings vary so inexplicably He remarks that "the confusion that can be induced by inadequate clinical observation and uncritical etiologic diagnosis is well shown by the literature published during the last few years on paratyphoid affections Most of these paratyphoid cases are not typhoids with a special etiology, but merely affections interesting on account of the peculiar reaction on the part of the blood serum Some were probably ordinary typhoid, others had nothing whatever to do with typhoid Other cases have been observed which did not differ from typhoid in any respect, although they were caused by the Schottmüller instead of the Eberth bacillus Typhoid fever is thus apparently not an etiologic unit, and it is merely splitting hairs whether we call the cases of typhoid not caused by the Eberth bacilli, paratyphoid, or whether we include them in the term typhoid with merely some additional term to express their etiologic peculiarity We can speak of a typhoid with a special etiology only when the symptoms of typhoid are present and Eberth's bacillus as the cause of the disease can be definitely excluded This is the only means to bring order out of the present confusion, the result of insufficient clinical observation and over hasty deductions, and show whether typhoid fever should be separated into several distinct diseases"

50 Relief of the Kidneys by Sweating—Strauss has been studying this subject on a large amount of material, comparing the findings by groups of patients with various affections He obtained the sweat for the purpose by the use of dry heat, a rubber sleeve fitting over the arm, a faucet in the sleeve bag allowing all the accumulated fluid to be drawn out into a vessel below Out of 200 tests he was able to obtain enough sweat for comparative research only in 80 In 25 of these 80 subjects some serious renal trouble existed, the others were patients for whom sweating procedures had been ordered generally on account of some neuralgic or rheumatic trouble The findings showed that the molecular concentration of the blood was frequently higher in the nephritic than in the non nephritic subjects, especially in the uremic nephritics The retention of water in cases of purely nephrogenic edema fulfills a compensatory purpose, as it serves to dilute the retained salts and other débris of metabolism The end products of nitrogen metabolism are not so important for the origin of the edema as the salts, yet the poisonous substances which cause the uremia must be sought among them, although we are not yet able to define them The pathologic importance of the retention of salts is demonstrated in another direction from that of the retention of the end products of nitrogen metabolism There is scarcely any department of internal medicine in which such opposite views prevail as in this question of the efficacy of sweating procedures for the elimination of nitrogenous molecules In the tests here described these molecules were in proportions in half the cases of nephritis far beyond that attained in three quarters of the non nephritic cases The amount of total nitrogen was generally somewhat larger than in the subjects with sound kidneys The practical conclusions of the research reported are to the effect that sweating procedures are liable to be beneficial in nephritis, and that uremic accidents need not be specially feared It is advisable, however, to supplement the sweating by copious ingestion of water to prevent evil consequences from the diaphoresis in uremic subjects If the edema increases, this is a minor ill, and the superfluous fluid can be easily tapped Strauss' experience has not shown that sweating had any influence in favoring the outbreak of uremic accidents On the contrary, his impression is that uremic subjects are improved by it, his empiric observation confirming the results of his research here presented

53 Carbonic Oxid Poisoning—In the first of the 2 cases reported the man had worked in an imperfectly ventilated room in which coke stoves were burning He suddenly presented symptoms suggesting a focus of softening or hemorrhage in the left hemisphere The permanent motor aphasia justifies the assumption that this focus involved the region of the foot of the anterior central convolution A history of mild syphilis a few years before suggests that the part may have been predisposed In the second case, the symptoms were about the same but rapidly retrogressed An accident to the woman's skull a year or so before may have afforded a predisposition She exhibited likewise cyanosis and edema of both hands, knee and forearms, with pemphigus-like blisters, subsiding by the tenth day, all but two rows of blisters on the right forearm, which terminated in necrosis, healing finally after several weeks They were evidently due to a neuritic process The poisoning occurred in consequence of shutting the damper in the stove pipe She and her husband were taking coffee together, when she lost consciousness and was not found until after twenty six hours The husband was dead

57 Removal of Urates and Capsule from Gouty Toe—In 1882 Riedel was summoned to operate on a great toe which had suddenly become swollen and intensely painful after a day's hunting, the subject a previously entirely healthy man of 45 The aspect of the toe suggested hallux valgus and suppuration in a bursa Under narcosis Riedel incised, searching for the assumed bursa, but nothing of the kind was found, merely a typical gouty deposit of urates, the capsule congested and set with pointed urate crystals He was horrified to find that he had operated on a gouty toe, but, having it open before him, proceeded to remove all the urates and extirpated also the capsule The patient was relieved at one stroke from his excruciating pain, and during the twenty two years since has had no further trouble of the kind He was so grateful that he went about advising other subjects with podagra to submit to an operation, but none heeded him and twelve years passed before Riedel had an opportunity to operate on another case of the kind The diagnosis in this second case had been similarly mistaken, bursitis with secondary suppuration having been assumed The results were as perfect as in the first case Of course this operative treatment should be restricted to isolated podagra, involving only a single toe But the results were so encouraging in his 2 cases that he can not refrain from advocating such a procedure in case of rebellious, excruciatingly painful gout, isolated at a single point The great toe is easily accessible, and at the same time very resistant Extensive detachment of the capsule does not impair its nutrition if the wound is left open In a gouty joint the inflammation is aseptic the exudate merely serous If a recurrence should develop the simple operation could be readily repeated In any event, the patient can count on years of peace in the interim

59 Spontaneous Healing of Cancer—Borrmann has examined histologically 265 cutaneous carcinomata, with over 2 000 microscopic sections, and has frequently found the so called foreign body giant cells But he does not admit that these giant cells are an indication of healing of the lesion They do not take up living cells, but merely form around dead detritus They were seldom or never found among the living cells of the cancer In 80 cases the lesion was an ulcus rodens, and giant cells were numerous, yet these lesions are inevitably slowly progressive In his experience the giant cells were more numerous in the rapidly growing cancers Deported cancer cells undergo horny transformation, and when killed by this process are then taken up by the giant cells The latter respect them so long as they are alive

62 Menstruatio Precox—Stein was called to a babe of 6 months, as genital hemorrhage was noted It recurred regularly month after month under the aspect of menstruatio precox He gives an illustration of the child at fourteen months, the menstruation having recurred eight times, and, curiously, always coinciding with that of the mother

64 For Mosquito Bites—Schill recommends to apply a little sodium bicarbonate, moistened to a paste, to take the sting out of a mosquito bite. It may be used in a concentrated solution To drive the insects away, he swabs the exposed parts with a 2 per cent. solution of thymol He has found these measures very effectual against mosquitoes and gnats

65 **Madeira as a Health Resort**—The Madeira Islands offer a combination of sea air, hill and mountain climate, freedom from dust and climatic vicissitudes, remarkably beautiful scenery and luxuriant vegetation, which make it a most promising health resort As has been mentioned in the news columns, a company has been formed to exploit Madeira for this purpose It will be possible there to have a tuberculous subject try different climates and altitudes under the supervision of a single physician, to determine which is best suited for him No research of this kind has yet been undertaken It is planned to make the sanitation of the island chosen ideal to have three sanatorium hotels at different elevations, with possibly a floating sanatorium, and to spare no pains to make it a perfect health resort, according to the most advanced ideas The names of Pannwitz and Wolff guarantee the high scientific character of the undertaking

68 **Kehr's Operation on Waldeck-Rousseau**—(See page 823) The patient was a man of 58 always healthy until icterus developed suddenly last fall after a violent emotion There was no pain, but the icterus continued with varying intensity until the spring, when there was gradual loss of appetite and strength An operation was undertaken the abdomen opened, and through a small incision at the outer margin of the right rectus the surgeons (Poirier and Terrier) palpated a small, hard lump in the head of the pancreas Without further exposure of the cystic and bile duct or of the pancreas, they made an anastomosis between the gall bladder and the jejunum The gall bladder was large and adherent and its contents were thick and gelatinous A week later there were three cholemic hemorrhages from the wound but the icterus pruritis and lack of appetite persisted Two months after the operation the icterus was still the same as before, the only change being that the patient was weaker and more miserable. When Kehr was summoned he found an emaciated extremely icteric patient, drowsy and already standing under the sign of cholemic intoxication No pain could be elicited by palpation, the liver was enlarged but smooth and nowhere hard, there was no ascites and no tumor The pulse was regular and strong 84 The urine contained a large proportion of bile pigment but no sugar nor albumin the feces were completely decolored The family physicians said that the heart and lungs were sound Kehr diagnosed chronic occlusion of the common bile duct, but whether from a stone or tumor, pancreatitis or adhesions it was impossible to say His experience with 947 gall stone operations had been that a cancer had been found in 70 per cent, a stone in 10 per cent and chronic pancreatitis in 20 per cent The findings in the case showed that the anastomosis of the previous operation had not accomplished its purpose The cystic duct may have been compressed by adhesions, which would explain the non functioning of the anastomosis Kehr's practice is always to aspirate the contents of the gall bladder before opening it. It is then incised and its contents evacuated Only when bile flows from the cystic duct is anastomosis permissible If the cystic duct be impermeable, then cystostomy, or better still choledochoduodenostomy should be considered Eventually cholecystectomy may be done supplemented by an anastomosis between the common duct and the duodenum In any event a long incision should be made to enable the conditions in the ducts to be ascertained correctly In the case in question the cystic duct may have been impermeable at the time of the first incision or may have become so later The patient had not lost his icterus, and an operation was the only resource left as he and his friends appreciated The age and sex spoke in favor of carcinoma, also the almost painless course of the trouble (possible likewise in case of stones), the severe icterus (possible in case of stone in the papilla), and the cachexia (possible also in case of occlusion from stone) Evidence against cancer was the sudden appearance of the icterus its fluctuations and the comparatively long course of the affection Cases of scirrhus of the pancreas are known which have run a two year course The patient was doomed without an operation, and if the trouble was of a non malignant nature it might cure, and, if malignant, it might prove palliative The chances were 30 per cent in favor of the former The patient was too weak to be taken to a hospital The abdomen was opened and a rather hard tumor was found in the pancreas behind the duodenum, studded with nodules, in all probability a carcinoma But, as chronic pancreatitis can induce a similar tumor formation, there was a possibility of this, especially as the glands were not enlarged and there was no trace of ascites On the strength of this possibility Kehr regarded it as his duty to provide for the evacuation of the stagnating bile A lobe of the liver presented and was taken for the gall bladder and incised the liver incision lengthening the operation by five minutes The gall bladder was found lax and almost empty, containing merely a little secretion and an undigested scrap of melon The cystic duct was completely occluded It had taken an hour to reach this point and the patient showed signs of collapse A tube was inserted in the gall bladder and an incision made in the common duct above the duodenum the bile spurting in a stream At this sudden evacuation of the liver the signs of collapse increased, and the intended choledochoduodenostomy or anastomosis between the gall bladder and common duct had to be abandoned Kehr had to content himself with draining the hepatic duct tamponing and closing the abdomen concluding the intervention in seventy five minutes On account of the extensive adhesions it was one of the most difficult operations he has ever done The patient was placed in bed the pulse grew a little stronger but after an hour disappeared, and death ensued before the second hour One of the lessons learned from this instructive case he adds is the value of a hospital environment Everything had presumably been prepared but the surgeon felt the lack of light from above he missed his adjustable operating table and the oxygen chloroform apparatus to which he was accustomed, although he had brought his own anesthetist with him

70 **Beck's Method of Operating on Hypospadia.**—Bötticher reviews 10 cases in which Beck's method was followed, the results compelling him to urgently corroborate König's assertion that the Beck technic has superseded all other methods of treating hypospadia The results are just as brilliant in very young children, but on account of the soiling of the parts during infancy the Giessen clinic has adopted the rule not to operate in cases of hypospadia until after the child is in its third year

71 **Rupture of Bladder During Bottini Electrolysis of Prostate**—Rosenstein describes a case of prostatic retention treated at Israel's clinic by Bottini electrolysis according to the usual technic During the process the bladder ruptured with the sound of an explosion Experimental research since suggests that the steam generated by the heat of the cautery was responsible for the explosion of the bladder He reproduced similar conditions in glass vessels and in rabbits' bladders, and found that an explosion followed the "Leidenfrost" phenomenon (the dancing of the drops of moisture on the white-hot knife isolated by their steam), and the sudden evaporation into steam as soon as the knife is cooled to a certain point by contact with the tissues He sees no way to obviate this disaster in performing the Bottini operation, and thinks that the danger from it should turn the scale in favor of prostatectomy

78 **Increase in Sugar-Forming Property of Blood**—Vigliani does not attempt to explain this phenomenon, but states that it occurred constantly in his experiments By modifying the metabolism, either with phloridzin or phosphorus, the sugar forming property of the blood serum was much augmented

80 **Symptomatology of Gastric Cancer**—Several puzzling cases are described In one there was no absence of HCl while no tumor nor specific formed elements could be discovered The diagnosis was based on the lack of appetite, repugnance for meat, absence of the signs of perforation and of vomiting after eating, the dry, straw colored skin, the cachexia and progressive character of the symptoms which suggested gastric ulcer In a second case the symptoms indicated stenosis of the pylorus, but there was no vomiting and no HCl In a third case the symptoms were those of pernicious anemia, but the progressive cachexia the difficulty in ingesting solid foods and the pains in the intrascapular region suggested a cancer in the lesser curvature The cancer in his fourth patient induced intermittent fever probably from absorption of toxic products A psychosis was the first signal of trouble in this case, soon followed by the discovery of a tumor in the stomach

81 **Unusual Onset of Certain Infections**—Several cases of typhoid pneumonia and erysipelas are described, in all of which the first manifestations were identical, all of a gastro nervous type They included vomiting, diarrhea colic unconsciousness pupil inertia, clonic convulsions, etc Notwithstanding the severity of the onset, the after course was unusually mild in some of the cases

85 **Simple Stain for Tubercle Bacilli**—Among the causes of failure to show up tubercle bacilli, Tarchetti mentions defective preparation of the material imperfect staining and the unfounded notion that a contrast stain is necessary He uses a simple technic, which includes spreading the material in a thin, even layer on cover glasses fixation with heat staining with phenic fuchsin or Ziehl's (fuchsin 1 part alcohol, 10, phenic acid, 5, and water 100), applied hot for ten to fifteen minutes, rinsing decoloring for one or two minutes in a concentrated alcoholic solution of picric acid, changing the liquid once The process concludes with brief rinsing, drying and mounting in balsam The advantages of this technic are its simplicity and the mild action of the picric acid while the persistence of the yellow stain gives the impression of contrast staining

87 **Technic of Subcutaneous and Intravenous Injections**—Oliva described two years ago, an instrument for this purpose, and his experience has impressed him more and more with its advantages The needle is enclosed in a canula, which protects against its penetrating too far The tube connecting it with the fluid to be injected is enclosed in a larger tube through which there is a constant flow of hot water The simple apparatus is illustrated in detail

90 **Hyperglobulia in Tuberculosis**—This article has been noticed editorially, page 742 Micoli noticed that a certain patient with incipient tuberculosis had six million red corpuscles The aspect suggested anemia rather than hyperglobulia These findings were repeated in a number of other cases of slight sclerosis of the apices Pondering on this remarkable hyperglobulia in apparently anemic subjects, he came to the conclusion that it was due to the action of small amounts of tuberculin, such as are produced by a small, circumscribed, inactive tuberculous focus Arsenic in small amounts promotes the regeneration of the blood, and he queried whether tuberculin might not have a similar action Experimental researches on animals treated with small doses of tuberculin have confirmed the correctness of this assumption He refers to Swan's report of hyperglobulia observed in 8 out of 26 tuberculous subjects examined (THE JOURNAL, xlii, March 12), and explains the scarcity of such findings by the general impression that the pallor of consumptives is evidence against hyperglobulia In reality, the color of the skin depends on the pigmentation and the activity of the capillary circulation It has nothing to do with the number of the red corpuscles Another reason is that the blood is seldom examined in the incipient phases of tuberculosis When the patients come to the clinics this phase is long past Many influences are known that reduce the number of reds, and there is nothing strange in the fact that other influences may increase them Among such influences must be reckoned the action of the tuberculin generated in some small, torpid process in the spleen or lungs In a recent case a patient with sclerosis of the apices had hemoptysis of a pint of blood twice, with ten days' interval The day after the second hemorrhage the reds numbered 5,600,000 Hyperglobulia in incipient tuberculosis is a means of differentiating an active from a torpid process The hyperglobulia that follows hemoptysis is an argument in favor of venesection as an effectual measure against certain of the symptoms of tuberculosis

91 **Tuberculin as Stimulus to Production of Red Corpuscles**—This article relates the particulars of the research referred to in the preceding abstract The writers found that large doses of tuberculin injected into guinea pigs had a very destructive action on the reds Moderate doses had no apparent effect on the reds but repeated small doses induce pronounced hyperglobulia The hemoglobin increased parallel with the number of the reds This effect was apparent in a few days, and persisted for some time It was so marked that the writers suggest that it might be utilized in the therapeutics of non tuberculous affections Subcutaneous injection of minute "refractory" doses of tuberculin might prove an effective means in combating non tuberculous anemia and chlorosis In such small doses tuberculin is perfectly harmless, and it is being tested now in the clinic
